In the patents which use induction methods treated in the preceding part of this paper the distances over which transmission is effected are comparatively short. A class of devices will now be investigated in which the inventors attempt to signal through a considerable space without using line wires. These inventions are described in the following patents: Dolbear, 350,299, October 5, 1886; Edison, 465,971, December 29, 1891; and Kitsee, 550,510, November 26, 1895.

In the patent to Dolbear, see Fig. 6, the transmitting circuit is shown at *A*, the receiving station at *B*. The induction coil *G* contains but one winding, which forms both its primary and secondary. One convolution of the coil is cut, the ends thus formed being connected with the poles of the battery f^1, which has a number of cells sufficient to establish a potential difference of 100 volts between the condenser H^1, which is attached to one terminal of the induction coil *G* and the wire *C*, which grounds the other end of the coil. A microphone transmitter *T* is included in the primary circuit. At *B* are located a magnetic telephone receiver *R*, condensers *H* and H^2, and a battery which the inventor says is arranged to charge the ground at *D* to an opposite potential from that at *C*.

Fig. 6

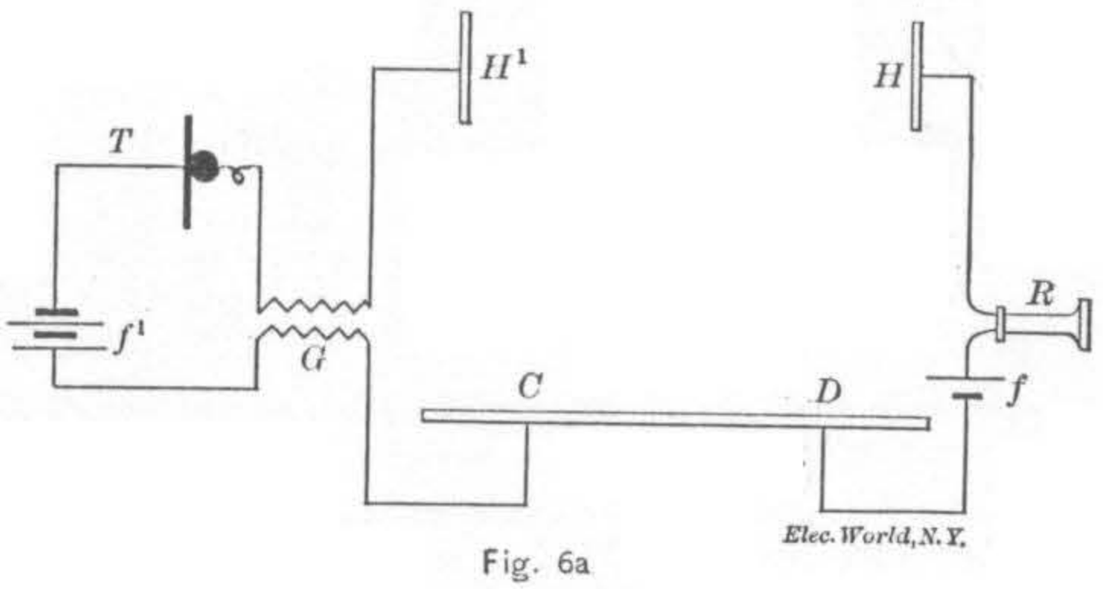

Fig. 6a

It would appear that several of the elements used by the patentee are unnecessary; he himself states that the condensers *H* and H^2 are not essential. Inasmuch as all the condensers are shown with one coating insulated, the capacity which they give to the system is small and their effect must be slight. The diagram, Fig. 6a, omits what appear to be inessentials, and gives perhaps a clearer idea of what occurs when the variable resistance transmitter *T* is vibrated. *G* represents the induction coil. H^1 and *H* form the two coatings of a condenser of small capacity. In addition to this condenser we have to take account of the fact that owing to the proximity of H^1 and *H* to the earth these plates form respectively the coatings of a pair of condensers, whose other plates are formed by the earth.

The capacity of this last-named pair is considerably greater than that of the condenser $H H^1$, for the capacity of a condenser varies inversely as the distance between the plates, and the distance from H or H^1 to earth is much less than from H to H^1. Consider now the circuit $C\ G\ f^1\ T\ G\ H^1\ H\ R\ D\ C$, in which a variable e. m. f. is produced by the vibration of T. There will be two paths for the alternating current produced by the change in the variable resistance T; one circuit beginning at the battery f^1 leads to the transmitter, then through one-half of the induction coil to H^1 to earth at C, and returns through the other half of the induction coil to the battery; the other circuit goes from H^1 to H, through the receiver R, and returns by way of the earth and through the path of the first circuit to H^1. It is the latter circuit that transmits the signals from T to R. Knowing the resistance, self-induction and capacity of each of these circuits, the amount of the e. m. f. of the battery and the variation in the resistance of T, the strength of the current in each of the two branches may be calculated. It will be seen that only a small proportion of the current produced in the local circuit $f^1\ T\ G\ H^1\ C\ f^1$ will be diverted into the receiving circuit at R. The battery at f, which is connected in series with the battery at f^1, increases the total e. m. f. in the signaling circuit, so that by means of it a given change in the resistance T will increase the current through the receiver R.

The apparatus used by Edison in his patent No. 465,971 is shown in Figs 7, 7a and 7b. In these figures two capacity areas C are placed at a suitable elevation and connected by wires l through his electromotograph receivers D and the secondary of the induction coil F to the earth. The electromotograph is a revolving chalk cylinder upon which a metal brush rests, giving a note of definite pitch (see patent No. 221,957 to Edison). When the current flows through the instrument the friction between the brush and cylinder changes, and this produces a note of different pitch. Any other form of receiver, which can be operated by alternate currents, may be substituted. A revolving circuit breaker, G, normally short-circuited by the key H, is placed in the primary of each induction coil. When the key is depressed a large number of impulses are produced in the primary, and by means of the secondary corresponding impulses are produced at the elevated condensing surface. These electrostatic impulses are transmitted inductively to the distant surface C, and are made audible by the current generated in the electromotograph connected in the ground circuit with the distant condenser plate. The intervening body of air forms the dielectric of the condenser, so that we again have the case of a circuit containing resistance, self-induction and capacity in series in which an alternating current is generated by a series of impulses of low frequency. It may be well to remark that Edison was one of the first to note the advantage of elevation for the condenser plate, as is shown by his statement in the patent; "that it is necessary on land to increase the elevation in order to reduce to a minimum the induction absorbing effect of houses, trees and elevations in the land itself."

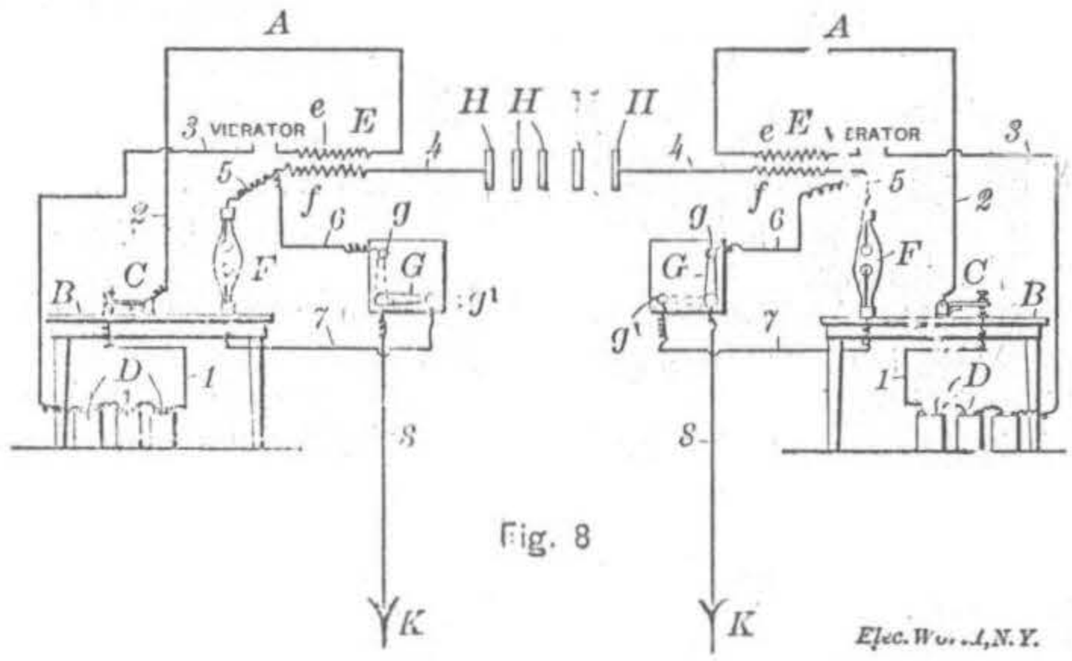

Fig. 8

The patent to Kitsee, which forms the last one of the electrostatic induction series, resembles the Edison patent in many respects, but uses a Geissler or vacuum tube for a receiving instrument. The closing of the key, in sending a current through the wire in which the Geissler tube is intercalated, causes a discharge in the tube which produces a continuous glow as long as the key is depressed. This permits the use of a dot and dash system of telegraphy. Referring to Fig. 8, a wire leads from the earth at K, through the switch G, and then either through the secondary f or through the Geissler tube F, and secondary to the line, according as the switch G is in the transmitting or receiving position. The local or signaling circuits consists of batteries D, a key C, a vibrator and primary e. With the switches in the position shown, on depressing the key C at the right-hand station, the vibrator is started, and the current induced in the secondary f, which alternately charges and discharges the plate H. These charges act inductively on the intermediate plates H, and finally induce a charge on the left-hand plate which creates a current in the secondary f which flows through the Geissler tube F, through the switch G to earth, thus causing a glow in the tube.

Fig. 7b

WAVE METHODS.

It seems difficult at first to separate wave methods from some of the electrostatic systems used by Dolbear, Edison and Kitsee, and indeed both may be regarded as belonging to the same generic class of induction as distinguished from conduction methods. It will serve to bring out the differences that exist between them if we digress somewhat in order to consult the examples furnished by other undulatory fields.

When sound waves are sent through the air, for instance, a great difference is recognized by the ear between a noise like the report of a cannon and a musical note. The former is produced by one or more shocks or sudden impulses, the latter by a series of waves of definite frequency and amplitude.

A similar distinction may be recognized when solid or liquid bodies are set in vibration. If a string is fastened at one end and the other held in the hand a single impulse may be sent along it by jerking the hand to one side, or a series of impulses or waves following each other in definite order, and at a uniform distance apart, may be formed by shaking the string transversely in timed sequence.

It is difficult to imagine an impulse formed by light or heat, for the period of such a wave is so short that a great number of them are sent out before the radian source can be eclipsed. A flash of light, which corresponds in its effect on the retina to the shock produced by a sound impulse or noise upon the tympanum, is, it

reality made up of a great number of waves, and is not due to a single light impulse. The persistence of impressions on the retina, the duration of which is about half a second, permits 250,000,000,000,000 light waves to act upon it before the sensation due to the first wave has died out.

In all these cases an impulse may be regarded as a single wave, but differing in shape and sometimes in velocity from the wave that exists in a train or series of undulations emitted by a suitable source of energy. In the electrical induction methods which have been described a single impulse or a number of them is generated, and these impulses produce their separate effects upon the receiver. One impulse dies out and an interval of time elapses before another is created. Their effect may be cumulative, as in the case of the Kitsee apparatus, where a series of impulses produced by depressing a key causes a continuous glow in the vacuum tube owing to the persistence of the impression on the retina, but the impulses themselves are separated by a distinct interval of time. This will more fully appear from the following considerations.

Suppose, as in the patent to Edison, 465,971, a Rhumkorff coil is used to charge the inducing plate, and assume that the current interrupter G is driven at a speed which will produce 100 breaks of the primary current per second. In each one-hundredth of a second two distinct charges of opposite sign are produced at the end of the open secondary; the one due to the make of the primary, the other to its break. In addition there are a number of oscillations of the make-induced charge as well as of the break charge. The shape of the curve which shows the charge of the ends of the secondary may be roughly indicated as in Fig. 9. This shape depends on a number of conditions, which include the resistance, self-induction and capacity of the two circuits, and is particularly affected by the presence of a condenser in the primary circuit[1]. For the present purpose it is sufficient to say that the curve is made up of two predominant impulses A and B, one positive and the other negative, each accompanied by a few considerable oscillations a and b, with a large number of neglible waves, a' and b', and a period of zero charge C between them. In some experiments by Bernstein[2] the frequency of the oscillation was as high as 20,000 per second. If the interrupter breaks the primary 100 times a second 200 oscillations will have time to die out between two breaks. Only a few of these can be effective owing to the large dampening factor of the circuits, and in the experiments referred to perhaps thirty oscillations were measurable, of which the first two or three alone may be regarded as of the same order of intensity as that of the initially induced wave. In pure wave methods on the contrary each wave of the train exerts its influence and is as effective as any other.

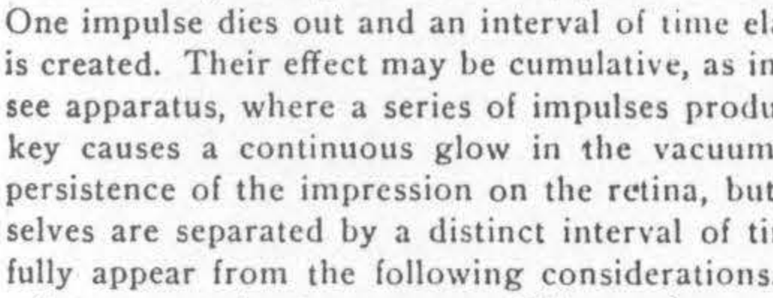

Fig. 9

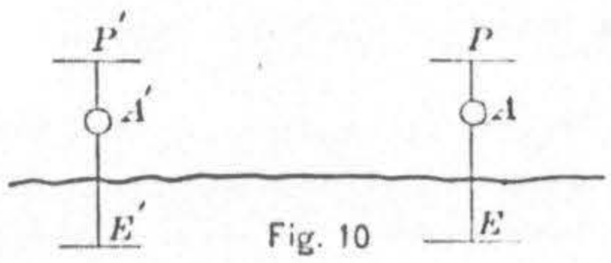

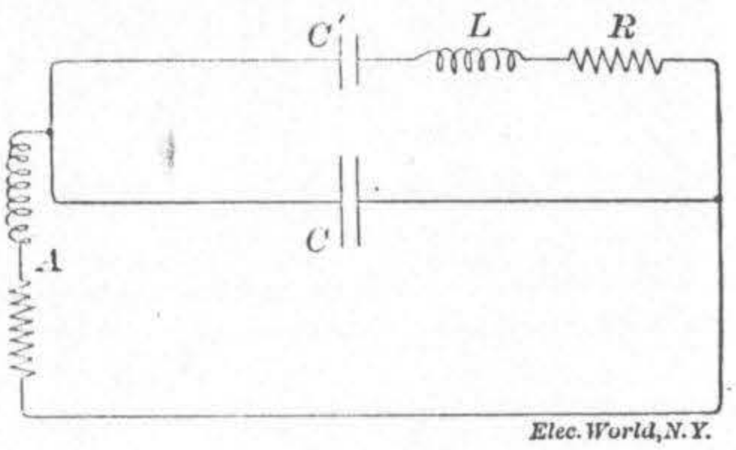

Fig. 10

Elec. World, N.Y.

Fig. 10 a

Another distinction which exists between impulse and wave methods is brought out by the principle of resonance. As is well known an oscillatory disturbance of definite period will exert a much greater effect upon a system tuned to the same period than upon one differing even slightly from it. A train of waves sent out by a sounding body will set a tuning fork of the same pitch into sympathetic vibration, but will leave undisturbed a fork of slightly different pitch.

A pendulum may be made to oscillate through a large arc by a series of weak forces if we so time their application that the interval between them is equal to the period of the pendulum. This has been used in a telephone selective signal system, in which each station is provided with a single pendulum of a definite time of vibration, which is determined by the position of a weight along its length. A number of electromagnets connected in series with a battery are arranged one at each station and each in position to attract its pendulum. Each subscriber can close the magnet circuit in suitable time sequence by means of a make and break pendulum whose period can be made equal to that of the call of any of the subscribers wanted. The magnets are thus all energized at each closure of the circuit, but the pendulum at the call station is the only one that responds, since its period is equal to that of the calling pendulum.

In optics, as is well known, a ray of light of a fixed wave length emitted by the sun will be absorbed by an incandescent gas in its photo sphere, which sends out waves of the same wave length, thus produced a so-called dark line in the solar spectrum. This has enabled physicists to determine the composition of the sun and "fixed" stars.

So an electrical oscillation of a definite period will exert, other conditions being the same, a much greater inductive effect upon one of equal period than upon one differing even slightly from it. The phenomenon of resonance is absent from electrical circuits in which impulses only are produced, for in them there is either an entire absence of period or this is not fixed but variable. Or as Lodge puts it[1], almost anything will respond equally well or equally ill to a dead-beat or strongly damped exciter.

Before proceeding to the discussion of the patents that have been granted for applications of wave methods it will be desirable to consider briefly a suggestion of Tesla which relates to a method of signaling by means of high frequency currents. The scheme, which is illustrated in Fig. 10, is described in his researches edited by T. C. Martin, 1894. Assume that a source of alternating currents of high frequency A be connected with one of its terminals to earth and the other to a body of large surface P When an electrical oscillation is set up at P this acts inductively on P', which constitutes a receiver. At any point within a certain radius of the source A a properly adjusted self-induction and capacity can be set in action by resonance. This method of signaling resembles that of the Edison patent 465,971, but an alternator is used without an induction coil, whose period, if we take for granted that a Tesla generator is referred to, may be as high as 20,000 reversals per second. No coherer is necessary, and the period of the waves emitted by the alternator, which is equal to that of the oscillations created in some of the induction methods described above, is of a much lower order than that of the Marconi and Lodge patents referred to below, in which waves are produced whose frequency may equal 10,000,000 per second. It will be seen that this device occupies an intermediate position in the development of the art.

The diagram in Fig. 10a shows the arrangements of the constants of the circuit. The generator A has a given self-induction and resistance; C' denotes the condenser at the receiving station in series with a suitable relay of resistance R and self-induction L. C is the condenser formed by the sending plate with the earth. It is shown as connected across the receiving circuit.

The case may be solved by the geometrical method, if the values of the constants are known. The calculation of the latter is a matter of some difficulty, since alowance must be made for the proximity of the condensing plates to the earth. The formula for calculating the capacity of two parallel plates

$$S = \frac{A}{4\pi d}$$

assumes that the field between them is uniform, which is only true when the distance between the plates is small compared to the distance of the plates from a foreign inducing body. This condition is just the reverse of the present case in which the earth acts inductively on the plate, increasing its capacity. In the absence of any experimental data it will be misleading to calculate a theoretical effect whose value in practice may be very different. Attention is

[1] See Colley, "Wied. Ann.," vol. 280, p. 109, and Lemstrom, "Pogg. Ann.," vol. 147, p. 354.

[2] "Pogg. Ann.," vol. 142, p. 54, 1871.

[1] See "The Work of Herz and Some of His Successes."

called to the fact, however, that the earth condenser C is of much larger capacity than C', so that very little current will be diverted through the receiving circuit. The capacity of the condenser C', moreover, is very minute, so that to secure resonance the self-induction of the circuit must also be made very small according to the formula

$$T = 2\pi\sqrt{LC}.$$

It is impossible to fix the value of self-induction by calculation when its value is so small; a cut-and-try method must be used until the proper length of wire is obtained which will neutralize the capacity.

The method used by Tesla, which has been described, resembles his proposed means for transmitting power at high altitudes, for which British patent 24,421 of 1897, and Swiss patent, 15,542 of 1897, have been granted to him, and is a step in the direction of his recent United States patent, 613,809, November 8, 1898, for controlling the movements and operation of a vessel or vehicle. Although both of these inventions relate to a different art, namely, that of transmitting power as distinguished from that of transmitting signals, yet by reason of their analogy to the present subject matter a brief description of them will be given. In the patent for transmitting power step-up and step-down transformers of high converting power are used, the former at the sending and the latter at the receiving station. One end of the secondary of the step-up transformer is connected to earth, the other to an insulated metallic sphere or condensing surface at a high elevation in the atmosphere. A similar arrangement is adopted at the receiving end and power is transmitted from one condenser plate to the other. The conditions which effect this method of transmission have been pointed out above.

In the patent, No. 613,809, for steering and propelling vessels a coherer circuit is used and local circuits which are energized by storage batteries for controlling the propelling and steering mechanisms. A steering motor is made to run in one direction by a local circuit thrown in by a relay and is driven in the reverse direction by another circuit and relay. The relays are energized by the coherer circuit, which includes a commutator and battery. The coherer circuit is made effective by the oscillator on shore. The boat is put into the water with the rudder to starboard, for example, the oscillator is started, the coherer is put into operation and the local circuit is thrown in which drives the rudder to port. This continues until the rudder reaches the port side. The coherer is then again operated which turns the commutator in the coherer circuit so as to throw in the local circuit which drives the rudder to starboard. The boat is thus made to steer its path in a series of zig zags. Signal lights may be flashed each time the coherer is operated to imitate the course of the vessel.

(To be continued.)

Telegraphing Without Line Wires—III.

By William Bissing.

(Concluded from last issue.)

Two patents have been granted in this country which make use of the method of signaling by electrical waves. One is the familiar patent to Marconi, 586,193, July 13, 1897, and the other is the patent to Lodge, 609,154, August 16, 1898.

In the patent to Marconi, Figs. 11 and 12 represent the transmitter and receiving apparatus when used for short distances. In them *c* indicates the induction coil, whose secondary is connected to the balls *d;* the primary is closed through the key *b*. *f* is a reflecting mirror of metal, and the sparking apparatus is placed at its focus. The spheres *e* lie between the knobs *d*, and when the induction coil sparks across at *d* it also of course produces sparking at *e*. This spark is the result of an oscillatory charge which is induced on the sphere *e*, and which sends out waves through the ether to the receiver, Fig. 12. This receiver consists of the coherer *j*, a glass tube containing metallic powder, each end of the column of powder being connected to a metallic plate *k* of suitable length to cause the system to syntonize electrically with the electrical oscillation transmitted. The tube *j* may be replaced by other forms of imperfect electrical contacts, examples of which are given by Lodge in the monograph above cited.* See the chapter on microphonic detectors. The reflector *l* collects the oscillations and projects them upon the coherer. There are two circuits at the receiver; one is the circuit embracing the coherer, the plates *k*, the battery *g*, and the magnet of the relay *n*; the other includes the battery *r*, the armature of the relay *n* and the trembler *p*. These correspond respectively to the line and local circuit of the ordinary Morse telegraph

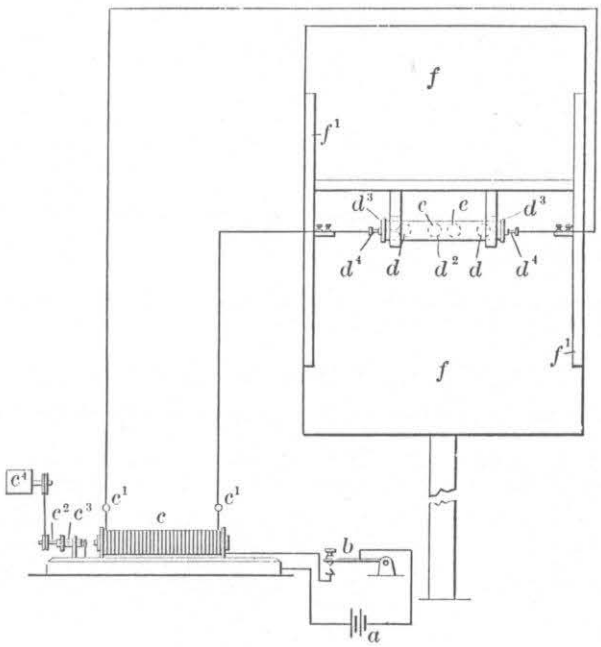

Fig. 11

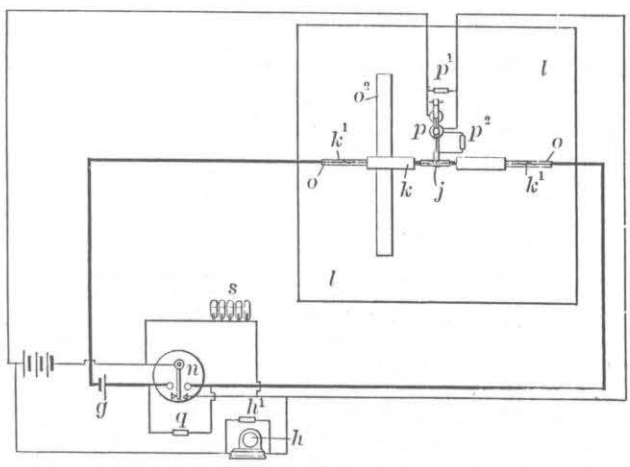

Fig. 12

The object of the trembler or decoherer is to disturb the filings after the spark has passed, and thus once more make their resistance too high to permit the passage of the current of the battery *g*. This decoherer is usually an electromagnetic bell, whose hammer is arranged to strike the coherer tube. The tapping is thus done automatically by the current started by the spark in the tube. In addition to these generic features of the invention there are a number of details which are shown in the figures. A telegraphic receiver *h* is placed in a circuit derived from the trembler bell circuit. The other devices shown at p^1 p^2 h^1 *q* and *s* are non-inductive resistances shunted about the electromagnets or circuit closures to counteract self-induction or prevent sparking. The arrangement usually adopted by Marconi is shown in Figs. 13 and 14, which are taken from Figs. 10 and 11 of the patent. One of the spheres *d* is connected to earth *E* and the other to a plate *u* suspended on a pole *v* and insulated from the earth. At the receiving station, Fig. 14, one terminal of the sensitive tube *j* is connected to the earth

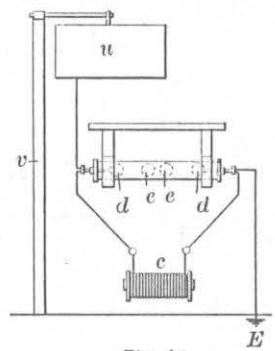

Fig. 13

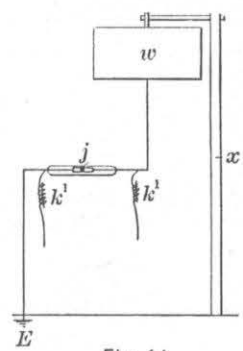

Fig. 14

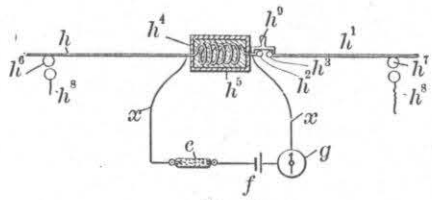

Fig. 15

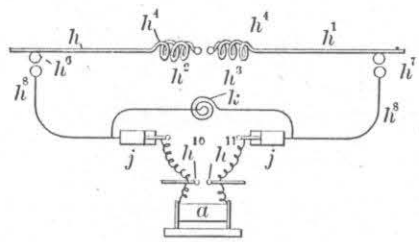

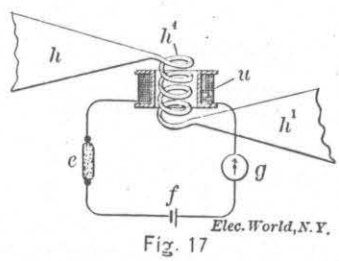

Fig. 16

Elec. World, N.Y.

Fig. 17

E and the other to an insulated plate *w* suspended on a pole *x*. The larger the plates of the receiver and transmitter and the higher the plates are suspended from the earth the greater is the distance through which it is possible to communicate. It was pointed out above that this elevation of the plates increased the proportion of the capacity of the plates with respect to each other to their capacity with respect to the earth, which augments the inductive action of one plate on the other. The theory of the coherer has been explained in several ways. The explanation given by Lodge in the monograph above referred to is that a kind of welding action between the particles takes place when the spark passes, which, of course, diminishes the resistance of the body of filings to the passage of the battery current.

*See "The Work of Herz and Some of His Successes."

Marconi describes in the specification a means of adjusting the capacity areas *k* so that the receiving circuit may syntonise electrically with the oscillations of the transmitter. In most of the experiments carried out by him with this apparatus, however, no tuning was attempted, and in the latest results that have been obtained by Slaby, circuits out of tune were used and a number of the minor features of the invention, such as the high shunted resistances to avoid sparking were omitted.

The patent to Lodge marks an important step in advance in this art. In the first place the waves emitted by the transmitter last longer, i. e., a greater number of waves are sent out at each discharge of the transmitter before they are damped out. Secondly, the receiver can be more effectively tuned or syntonized to respond to a definite pitch of the signaling instrument. Lodge's invention is shown in Figs. 15, 16 and 17, which are copies of Figs. 3, 4 and 13 of the patent.

Fig. 15 shows a combined radiator and receiver. In it h^8 indicates wires leading to the Ruhmkorff or high potential coil: *h* and h^1 constitute the capacity areas, h^4 is the syntonizing self-induction coil embedded in insulation h^5; h^9 is a sort of circuiting switch; *e* is the coherer, *f* the battery and *g* the receiving instrument. When in use as a radiator the gap between the discharge knobs h^2 and h^3 is left open; when utilized as a receiver the gap is closed by the switch and the coherer, battery and receiving instrument *g* are connected through a thin wire *x* from each end of the coil h^4. The above arrangement permits one instrument to be used as a transmitter or receiver by simply throwing a switch. In Fig. 16 a Leyden jar or other suitable condenser *j*, able to stand a high potential, is interposed in the wires h^8, leading from the Ruhmkorff coil, so that the knobs are supplied from the outer, that is, the uninsulated coat of each jar, while between the inner coats a third spark gap is arranged, called the starting gap, which consists of suitable knobs, h^{10} h^{11}. The outer coats of the jars are joined by an induction coil of thin wire, *k*, so as to permit thorough charging. When the discharge occurs this wire acts as an alternative path or bypass, but does not prevent the sparks at the supply gap.

In Fig. 17 the syntonizing coil of the resonator is surrounded with another or secondary coil *u*, constituting a species of transformer. This latter coil is made a part of the coherer circuit, so that it is secondarily affected by the alternating currents excited in the conductor of the resonator. The coherer is thus stimulated by the current in this secondary coil rather than primarily by the currents in the syntonising coil itself, the idea being to thus leave the resonator freer to vibrate electrically without disturbance from attached wires.

The persistance of vibration of the waves of the transmitter is due to the self-induction coil which is inserted between the capacity areas of the radiator. This effect is analogous to that due to increasing the weight, and therefore the moment of inertia of a flywheel which prolongs the number of revolutions the wheel makes, beginning with a given angular velocity, before it comes to rest. The following extract from Helmholtz's "Sencations of Tone," page 62, may make the action of the induction coil clearer by setting forth the parallel case for sounding bodies:

"Bodies of small mass which readily communicate their motion to the air and quickly cease to sound, as for example stretched membranes or violin strings, are readily set in sympathetic vibration. The limits of pitch capable of exciting sympathetic vibration in such bodies are somewhat broad. Massive elastic bodies, on the other hand, such as bells and plates, are not so easily excited. It is necessary to hit the pitch of their tone with much greater nicety in order to make them vibrate sympathetically. They will, of course, continue to vibrate for a longer period than the others."

Attention is called to the persistency of the sounds of heavy elastic bodies and nicety of regulation, which is required to set them in sympathetic vibration, just as in an electric circuit containing an induction coil, as used by Lodge, the oscillations last longer and the syntony is more accurate than when the coil is omitted.

With the patent to Lodge it will be necessary to bring this article to an end. It will be readily granted that there are still numerous problems to be solved in the art of wireless telegraphy. It will be necessary to increase the distance over which transmission may be effected, to add to the certainty and secrecy of the message, to prevent the disturbing and absorptive effects of the intervening media, to increase the sensitiveness without impairing the efficiency of the receiving instrument, before we can hope to replace the Atlantic cable and its costly appurtenances with a pair of syntonized radiators and receivers.

October, 1898.

The New York Herald January 15, 1898

ELECTRIC CURRENT TO KILL BACILLI

Nikola Tesla Proposes to Annihilate Disease by Using Millions of Volts.

RESULT, NEW LEASE OF LIFE

How This Tremendous Force Is To Be Generated Has Not Yet Been Revealed.

NO INSULATOR FOR PATIENTS.

Even Consumption, It Is Asserted, Will Be Routed by the New Discovery.

Nikola Tesla, whose boldness in conceiving astonishing uses to which electricity may be put, has given the scientific world surprises from time to time, has a new proposal, and one which will arouse widespread interest and comment.

He now proposes to destroy the bacilli of all diseases by applying millions of volts of electricity to persons afflicted. The tremendous force is to be applied in such a manner that the vital organs will be free from harmful effects and so that the bacilli will be drawn from the system.

The tremendous current which Tesla proposes to apply will not be sent through the body, as in the cases of persons executed by electricity, but will run along the surface.

The new plan for destroying disease germs, including even those of consumption, was outlined recently in an exhaustive paper which the electrician read before the Electro-Therapeutic Society, and created deep interest.

TO USE MILLIONS OF VOLTS.

It had been supposed that Tesla's feat in generating a current of fifty thousand volts, announced some time ago, was the limit, but he told me last evening that the cure proposed involved the use of millions of volts, applied in such a manner as not only not to harm the patient but to remove from his system all the bacilli lodged there and renew his store of energy.

The matter became public yesterday, when in despatches from Washington it was announced that a New York lawyer was filing with the patent office the papers necessary to protect the discovery. Mr. Tesla said yesterday that he had applied for no patent and that no one was acting for him in that respect, but he added that the news contained in the Washington despatches was probably based upon new features in the use of electricity of which he treated in the paper he read recently in this city.

Inquiry was made at the patent office by the HERALD'S Washington correspondent, and he was told that as yet no patent for any electrical process for germ destroying had been applied for, and that nothing was known of any application for a patent protecting any contrivance intended for such uses.

NO GLASS CASE.

Mr. Tesla told me that the Washington accounts of his discovery were incorrect in some particulars. It was said, for instance, that it was proposed to place the patient in a glass case and to apply the tremendous current from without, the glass, not being an absolute non-conductor, serving to permit the application of the current without causing too great a shock and to distribute it so that the repeated charges of static electricity would destroy the various forms of bacilli without injury to the patient. Mr. Tesla said of this description of his process:—

"That is wrong, technically. There will be no glass case such as is spoken of. I have no time to go into the matter in detail now, beyond telling you that it is my plan to apply several millions of volts of electricity to the surface of the body and draw out the germs.

"No, death would not follow the use of a current so tremendous. The patient would not be injured, but would receive a new store of energy. I think the reports from Washington are a result of my recent presentation of new features in the use of electricity for the cure of disease."

Just how Mr. Tesla proposes to generate a force so mighty he did not say. That is his secret. While a current of 1,500 or 1,800 volts suffices to kill a man instantly when applied in a certain way, a vastly greater amount of electricity applied in a manner altogether different, it is explained, may be of beneficial effect, and the patient may became practically a new man as far as his store of vital energy is concerned.

WHAT OTHER EXPERTS SAY.

Lack of details concerning the manner in which Mr. Tesla proposes to apply static electricity for curative purposes prevented a discussion of the value of the alleged discovery by medical men yesterday. Dr. Cyrus Edson pointed out that it is physically impossible to make static electricity permeate all parts of the human body, as it does not penetrate beyond the surface. If it did, the germs of disease might be destroyed by it.

Thomas A. Edison, when the matter was brought to his attention, in Orange, N. J., yesterday, said he had applied for no patent in connection with the use of electricity for germ destroying, and knew nothing about the discovery.

Dr. F. S. Kolle, who is in charge of the electro-therapeutic department of the Electrical Engineer Institute, at No. 120 Liberty street, and who has written extensively of the Roentgen discovery and kindred matters, was much interested when told of the discovery of Tesla yesterday. He told me that Tesla and others had produced apparatus that would generate two and a half million volts of electricity, and continued:—

"I see no reason why a glass case should be used. Any man can take a million volts direct into his body and not be injured by it, but benefited instead. The reason that 50,000 volts did not kill Tesla when he took that strength of current is that the cells in his body did not have time to contract in response to it. Much less would have killed him instantly. Much more is all the safer.

"It is just such a case as that of a bullet going through a window pane. At high speed it will cut a clean hole and will not crack the glass. The particles have not time to spread during the period of impact.

WHY ELECTRICITY IS LIFE.

"As to the benefit of so great a current, we say it as a proverb that electricity is life, and the scientific meaning of that saying is that it oxidizes the tissue.

"I have long held the theory, though I have never made it public before, that the renewal of energy and vitality which follows eating long before the three or four hours necessary for ordinary digestion have passed, is directly due to the production of a small electrical current generated by the action of the acid secreted by the stomach's mucous membrane upon the metallic elements which make up the food ingested.

"The exterior application of an oscillatory current of high frequency would have a similar effect, greater as the current went higher, but whether proportionately greater I cannot say. So, therefore, the use of such a current would restore vitality and be an ally and aid to the food taken into the stomach. It could never take the place of food, of course, for, while it could supply oxygen, it could not give the carbo-hydrates necessary to existence. Therefore its use would not diminish the amount of food needed. The person using it, however, would have a greater ability to work and a more brilliant intellectuality.

"Would a million volt current kill the bacili of disease in the body? I do not know. I do not know whether a fifty thousand volt current can do it. I am not aware that any experiments of that kind have been made. But oxidization does kill bacilli of all kinds, and as those currents produce it there is good reason to believe that part of the claim for this discovery. What has not been heretofore known is how much oxidization of tissue will kill bacilli therein. Perhaps that has now been found out. It all seems feasible, except the talk about a glass cage."

A PAPER read by Mr. Nikola Tesla at a meeting of the Electro-Therapeutic Society in Buffalo not long ago, suggesting a method of killing disease germs in the human body by means of static electricity, has again been brought to public notice by the rumor that a New York attorney was a day or two ago in Washington filing with the Patent Office the necessary papers for protecting the invention. In a word, Mr. Tesla's idea is to apply a current at everal millions of volts to the surface of the body, and by oxidizing the tissue kill all bacilli that may be present. The details of the process, as for instance how Mr. Tesla proposes to produce such a high potential current and how it would be applied for curative purposes, has as yet not been made public.

Vol. XXVII. NEW YORK, JANUARY 19, 1899. No. 559.

The Upper Regions of the Air as Current Conductors.

THERE are a number of striking and important electrical and magnetic phenomena, which though giving rise to speculation and hypotheses, have not yet been explained by generally accepted theories. Among these we may mention the earth's magnetism and electrical storms. A satisfactory explanation of the cause of these phenomena would indeed be a great step in advance on our present knowledge and might indeed lead to results now scarcely within the limits of legitimate speculation.

Undismayed by the numerous and conflicting theories of the past, Prof. W. P. Trowbridge has recently come forward with a new hypothesis which, even if not unassailable in all its details, is nevertheless highly interesting and deserving of more than passing notice. As explained by him in this month's "Forum," if we ascend a sufficient distance the layer of air which surrounds the earth we there find all the conditions requisite for the production of the two phenomena mentioned above, and incidentally a medium which can transmit X-rays. Having in mind the fact that at great altitudes the air is so rarefied as to constitute a good conductor and the further fact that the air absorbs numerous rays emanating from the sun, especially those of short wave length, Prof. Trowbridge asks: Can the disappearance of the short waves of light have anything to do with the production of electrical storms and the appearance of this weird new form of energy? and, Can this disappearance be connected in any way with the production of magnetism of the earth?

Starting with the proposition that the energy involved in the production of these phenomena emanates from the sun primarily, Prof. Trowbridge propounds the further question whether it is not possible that the short waves of energy may in some way produce electrical and magnetic effects in the upper regions of the air, and thus, being transformed, fail to manifest themselves as light at lower altitudes. It is Prof. Trowbridge's main contention that the sun's rays contain the short wave lengths assigned to the X-rays and that, though absorbed by the lower strata of the atmosphere, they exist at the higher altitudes; and that they are instrumental in producing the electricity of the atmosphere and the magnetism of the earth.

Fortifying himself by some recent researches Prof. Trowbridge holds that the solar X-rays give an electrical charge to our atmosphere. The rotation of the earth on its axis would then cause an accumulation of electricity on one side of the earth and a diminution of electricity on the other. We should, therefore, expect a fall of electric pressure between the regions just entering daylight and those in the full glare of the sun. This condition would direct the resulting electric current from east to west, or in the direction opposite to that of the earth's rotation.

The current thus established, according to Prof. Trowbridge, is sufficient to account for the main points of his thesis. The electrical disturbances, such as thunder storms, in the lower regions, might thus be accounted for as being the result of great commotions in the air which constitutes a vast atmospheric sea and due to a local descent of high electrical conditions prevailing in the upper regions. The Northern Lights, again, may, according to the same theory, be due to a dissipation of a portion of the electrical discharge, through layers of rarefied and well conducting air.

Reasoning in an analogous way, the currents existing in the upper well-conducting regions act as a solenoid upon the earth beneath and form the magnetic poles observed. In support of the solenoidal action, Prof. Trowbridge points out that on no other theory could the great distance between the north and south pole be explained; no permanent magnet could have any such length without exhibiting consequent poles. As no currents adequate to produce the poles of the earth have yet been discovered in or on the earth, they may, if they exist, circulate in the upper regions.

This entire reasoning depends of course upon the assumption of the great conductivity of the rarefied, upper regions of the air. This brings Prof. Trowbridge to the question of the practicability of Mr. Tesla's recent proposal to utilize those regions as a conducting medium for the electrical transmission of power. Prof. Trowbridge's experience, based on experiments in the laboratory, lead him to the belief that the method is impracticable. Thus, before one reached the height of ten miles—where there is greatly increased conductivity—the electricity would have deserted the terminal raised to that height and would have flowed to the ground, instead of taking the path of the air to the distant station! In the dark, one can see the reason for the diminished length; for luminous discharges are noted between the high tension apparatus and the floor of the room. The inductive effect is so great that sparks can be drawn from the brick walls and the neighboring gas pipes! The time when the upper regions of the air will be thus used commercially seems therefore to Prof. Trowbridge far distant.

As we have stated above, Prof. Trowbridge's hypothesis is not without objections. Thus, we may ask, how according to that theory, can the fact be accounted for that auroras have been observed within but a hundred yards of the surface of the earth, where there could be no possible adequate rarefaction of the air? Still the hypothesis is interesting and, at least, si non e vero e ben trovato.

Apropos of the suggestion of utilizing the upper strata of the atmosphere as a current conductor, we are reminded by some of our readers of the fact that the idea was put forth some twenty-five years ago by Mr. S. J. M. Bear for telegraph work. And now, Chicago, not to be outdone, has a claimant to the same region, in the person of Mr. Archibald J. Robertson, who claims to have covered the idea in a patent granted to him in 1892. From what he says, it looks as though we shall presently learn of a suit for infringement brought against Mr. Tesla. If a Chicago man can lay claim to giving the main idea of Cyrano de Bergerac to Rostand, why may not another from the same city of unlimited area and ideas claim all the upper atmosphere and its attributes as his own? To avoid strife and the establishment of a grinding monopoly in the future we would suggest that all claims in those regions be now staked and filed in a Government Air Bureau specially organized by Dr. Cleveland Abbe for that purpose, and to be called the Government Rarefied Air Office, with regulations patterned after those of the present Land Office. This might at once mitigate the coming wars with squatters and interlopers.

Tesla Polyphase Patents Declared Invalid in Germany.—The New York *Electrical Engineer* says that the Reichsgericht of Germany has confirmed the decision of the lower courts declaring the Tesla polyphase motor patents invalid. The court reviewing the case, holds that the patents are void owing to their not having been worked according to the requirements of the German patent law. The court goes on to say, however, that even if the patent had been sustained on that ground, it would have been, nevertheless, invalidated owing to the fact that the invention was not adequately described in the German patent specification, whereas the American patent specification is clear. It is understood that the Helios Company, of Cologne, who control the Tesla patents in Germany, will no longer contest the suits which it has brought against several parties in Germany.

ROENTGEN LIGHT NOTES.

BY WILLIAM ROLLINS.

NOTE XLII—ON GENERATOR TERMINALS IN OIL.

Soon after Roentgen's discovery was announced, Professor Trowbridge cooled the discharge tube by oil. Mr. Tesla developed the method and published a figure of the apparatus. Like most of the early work it has been lost, because the great experimenters will not take the time to say the same thing over and over. While using this method I noticed a phenomenon new to me. As I can not find it mentioned it is here described. At the anode end of the tube the oil fairly boiled, not in temperature but in appearance, the surface being raised and in constant motion. This was striking, for no bubbles were formed. At the cathode end there was less disturbance, though a match appeared alive, darting to the terminal and rushing back again, repeating the motion at short intervals. When the tube was removed and the terminals placed 15 inches apart the phenomena were very marked, the surface of the oil near the anode being raised a quarter of an inch. We had here in the liquid dielectric a similar process to what takes place in air; in other words, a liquid brush discharge.

NOTE XLIII—BURNING FROM ROENTGEN TUBES.

In Note 12 I showed that a severe burn could be produced by a tube giving no Roentgen light, the pressure being so low that, with the potential used, no discharge went through the tube. In this case, therefore, the burning was due to the electric discharge and not to Roentgen light. On the other hand I stated that prolonged exposure to the discharges from a vacuum tube did not burn me because I used a Tesla screen. I also tried the experiment in another way. The vacuum was made so high that the greater proportion of the Roentgen light was of short-wave length, what is commonly known as penetrating X rays. Using the same screen I could not burn myself. I then arranged the apparatus so that the radiation consisted chiefly of short waves, what is known as least penetrating X rays. I could not, with exposures of hours in a several day investigation, produce any effect with the screen to protect me. Now, as Roentgen rays are short ether vibrations, whose length depends upon the temperature to which the particles of the cathode discharge are raised by their impact on the target, we should not expect them to produce much more severe burns than sunlight, also an ether wave phenomenon; the chief difference, except in amount, being that in addition to the rays present in sunlight when it reaches us a tube gives off radiations of higher pitch. Prof. E. Thomson has said that the sun probably gives these short vibrations also, and Madame Curie, in attempting to reach the shore of that mysterious ocean of power from which evermore uranium and thorium draw force, started with the idea that all space is filled with more subtile radiations than those of Roentgen. Elster and Geitel doubt this, because carrying these metals to the bottom of a mine 3,000 feet below the surface did not affect them. To me this objection is without force, because I had previously stated in these notes that we could produce a vibration to which worlds would be transparent, the Roentgen rays being but an octave in the grand gamut. An eminent authority has stated, and repeated his statement, that burns are due to X rays of low penetrating power, which are most stopped by the tissues, and that a sheet of suitable material, in other words a Tesla screen, may prevent burns by stopping these waves. I, of course, do not know enough to criticize this view, but mention some facts which should be considered by those who hold it. I have always used a Tesla screen of wire netting, through whose open meshes all rays pass freely. This construction has been made necessary by the imperative need of being able to safely watch for hours the tubes with which I was experimenting. Moreover, the less penetrating rays are most stopped by bones, which on this theory should be affected.

NOTE XLIV—ON HYDROGEN AND OXYGEN.

In this journal for December 1, 1897, a tube was figured with an hydrogen vacuum, and in the number for February 9, 1898, one with an oxygen vacuum. As the latter type of vacuum is perhaps being made unduly prominent, the matter will bear speaking of again. When we wish to make most of the light of short waves use hydrogen, because the same electro-motive force causes its particles to strike the target at a higher velocity, and therefore they are raised to a higher temperature, producing more short waves. In this case the target should be of the most dense metal, because, as stated in Note XXXV, the shock of impact is more sudden, the heat in consequence reaching a higher degree. To generate light of mostly longer waves use oxygen, which, being heavier, strikes the target with less velocity when the electro-motive force is the same. The particles are therefore not raised to so high a temperature, the waves being in consequence longer. Oxygen has one advantage for a tube with an uncooled target—it does not disappear so rapidly, the vacuum requiring less frequent adjustment. These statements apply to the ordinary types of commercial apparatus. With generators of moderate electro-motive force, large amperage and enormous frequency, other considerations come in.

NOTE XLV—ON HARMONICS.

After reading the notes published in this journal it is desirable to add a few words on some points already touched upon. The wave length of the Roentgen light was said to depend upon the velocity with which the particles struck the target and upon the temperature to which they were raised by the force of impact. As these particles are small the heat declines rapidly, the train of waves being short, the length of the waves increasing as the heat declines. It was also stated that the amount of Roentgen light depended upon the amperage utilized at the target, and as this is not the same as saying that to increase the light it is only necessary to increase the amperage, I dwelt at some length upon the necessity of harmony between the tube and generator, a matter which each new day of experience showed to be of prime importance. For example, it is possible to use the entire output of my large Holtz machine, probably the most powerful of its type in America, and not get as much light from a tube as when it is excited by a very small machine of the same type. I do not believe that any electrician but Mr. Tesla realizes the imperative necessity for harmonics, if we wish to economically convert a long into a short vibration, and it appears to me that the remarkable photographs he has shown in this journal of electricity converted into light are due to his recognition of this principle.

The poets are the true seers, and the discoverers whose minds are most like theirs are those who first catch glimpses of remotest laws. I have already quoted Emerson as saying "the atoms march in tune," and again refer to this as showing the necessity of adjusting the apparatus so that the discharges from the concave terminal shall follow each other in regular order, and at periods which are harmonics of the wave length of the Roentgen light we wish to generate by the impact of these discharges on the target. Only in this way can we get the most light with the least amperage. Trowbridge has shown that an apparently single surge is composed of a multitude. We must adjust the rate of these, for so simple a thing as changing the condenser discharge with a static machine will make the difference between a well or badly lighted tube.

Torpedo Boat Without a Crew.....N. Tesla.....New York Journal

"My submarine boat, loaded with its torpedoes, can start out from a protected bay or be dropped over a ship side, make its devious way below the surface, through dangerous channels of mine beds, into protected harbors and attack a fleet at anchor, or go out to sea and circle about, watching for its prey, then dart upon it at a favorable moment, rush up to within a hundred feet if need be, discharge its deadly weapon and return to the hand that sent it. Yet all through these wonderful evolutions it will be under the absolute and instant control of a distant human hand on a far-off headland, or on a warship whose hull is below the horizon and invisible to the enemy.

"I am aware that this sounds almost incredible, and I have refrained from making this invention public till I had worked out every practical detail of it. In my laboratory I now have such a model, and my plans and description at the Patent Office at Washington show the full specifications of it.

"As to the mechanism which is to be stored in this submarine shell: The first and most essential thing is a motor, with storage battery to drive the propeller. Then there are smaller motors and batteries to operate the steering gear, on the same principle that an ordinary vessel is now steered by steam or electricity. Besides these there are still other storage batteries and motors to feed electric signal lights. But in order that the weight of machinery shall not be too great to destroy the buoyancy or make the boat go too deep in the water, compressed air motors will also be used to perform certain functions, such as to fill and empty the water tanks which raise the boat to the surface or sink it to any required depth. Pneumatic air or motors will also fire the torpedoes and pump out the water that may leak in at any time.

"This submarine destroyer will be equipped with six fourteen-foot Whitehead torpedoes. These will be arranged vertically in two rows in the bow. As one torpedo falls into position and is discharged by pneumatic force, another torpedo, by the force of gravity, falls into the position of the first one, the others above being held up by automatic arms. They can be fired as rapidly as a self-cocking revolver is emptied or at intervals of minutes or hours. The discharge takes place through a single tube, projecting straight in the bow. The small amount of water which leaks through each time is caught by drain pipes and a compressed air pump instantly expels it. As each torpedo is expelled a buoyancy regulator will open the sea cocks and let enough water in the ballast tanks to make the buoyancy uniform and keep the boat at the same distance beneath the surface.

"This submarine destroyer will carry a charge of torpedoes greater than that of the largest destroyers now in use. Those vessels of five hundred tons each, which cost the Government $500,000, carry but three or four torpedoes, while this simple submarine destroyer, which can be built for $48,000 to $50,000 or less, will carry six torpedoes. It will have also the incalculable advantage of being absolutely invisible to an enemy, and have no human lives to risk or steam boilers to blow up and destroy itself.

"All that is necessary to make this submarine boat subject to perfect control at any distance is to properly wire it, just like a modern house is wired so that a button here rings a bell, a lever there turns on the lights, a hidden wire somewhere else sets off a burglar alarm and a thermal device gives a fire alarm.

"The only difference in the case of the submarine boat is in the delicacy of the instruments employed. To the propelling device, the steering gear, the signal apparatus and the mechanism for firing the torpedoes are attached little instruments which are attuned each to a certain electro-magnetic synchronism.

"Then there is a similar set of synchronistic instruments all connected to one little switchboard, and placed either on shore or on an ordinary warship. By moving the lever on the switchboard I can give the proper impulse to the submarine boat to go ahead, to reverse, throw the helm to port or to go ahead, rise, sink, dsicharge her torpedo or return. It might seem that some great power would be necessary to be projected across the miles of distance and operate on the far-off boat. But no; the power is all stored in the submarine boat itself—in its storage batteries and compressed air. All that is needed to affect the synchronistic instruments is a set of high alternating currents, which can be produced by my oscillator attached to any ordinary dynamo situated on shore or on a warship.

"How such an apparently complicated mechanism can be operated and controlled at a distance of miles is no mystery. It is as simple as the mes-

senger call to be found in almost any office. This is a little metal box with a lever on the outside. By moving the crank to a certain point it gives vibrating sounds and springs back into position, and its momentary buzzing calls a messenger. But move the crank a third further round the dial and it buzzes still longer, and pretty soon a policeman appears, summoned by its mysterious call. Again, move the crank this time to the farthest limit of the circle, and scarcely has its more prolonged hum of recoil sounded when the city fire apparatus dashes up to your place at its call.

"Now, my device for controlling the motion of a distant submarine boat is exactly similar. Only I need no connecting wires between my switchboard and the distant submarine boat, for I make use of the now well-known principle of wireless telegraphy. As I move this little lever to points which I have marked on a circular dial I cause a different number of vibrations each time. In this case two waves go forth at each half turn of the lever and affect different parts of the distant destroyer's machinery.

"How such submarine destroyers should actually be used in war I leave for naval tacticians to determine. But it seems to me that they could best be operated by taking a number on board a large, fast auxiliary cruiser like the St. Louis or St. Paul, launch them, several at a time, like lifeboats, and direct their movements from a switchboard placed in the forward fighting top.

"In order that the director of the submarine destroyer may know its exact position at every movement, two masts, at bow and stern, will project up just above the water, too minute to be seen or hit by an enemy's guns by day, and by night they will carry hooded lights.

"The lookout placed in the fighting top could detect a hostile ship off on the horizon while the auxiliary cruiser's big hull is still invisible to the enemy. Starting these little destroyers out under direction of a man with a telescope, they could attack and destroy a whole armada—destroy it utterly—in an hour, and the enemy never have a sight of their antagonists or know what power destroyed them. A big auxiliary cruiser, used to carry these submarine destroyers, could also carry a cargo of torpedoes sufficient to conduct a long campaign and go half-way around the world.

"She could carry the gun-cotton and other explosives needed to load torpedoes in safe magazines below the water line, and do away with much of the danger of transporting loaded torpedoes. When necessary for use the war heads could be loaded, fitted to the torpedoes, and the submarine destroyers fully equipped.

"A high, projecting headland overlooking a harbor and the sea would also be a good point on which to establish a station and have the destroyers laid up at docks below and ready to start."

Mr. Tesla's New Theory of Artificial Light.

EVER since Mr. Tesla practically finished his multiphase motor work, now more than ten years ago, he is understood to have devoted much of his time to experimental work in the domain of electric lighting. His first attempts led him in the direction of the vacuum tube and his brilliant lectures on that subject, both here and abroad, must still be fresh in the minds of many of our readers. But even in those lectures Mr. Tesla devoted considerable space to the discussion of the employment of solid, refractory materials as light giving media under the influence of high frequency currents. It would seem, however, that of late Mr. Tesla has greatly modified his views as to what is a sine qua non in a successful electric illuminant. At least we are led to this belief after reading an interview had with him by Mr. Charles Culver Johnson, appearing in the "Philadelphia Press." We must confess at the outset that we are unable to follow the interviewer at all points, but we gather in general that Mr. Tesla has come to the conclusion that electricians have all been on the wrong track in the past in working on so-called non-refractory or heat proof materials as light giving bodies. There are, Mr. Tesla says, a few bodies which for a time seem to be indifferent to heat, but he has found that not one of them will endure a continuous strain. In this new discovery, we are told, vibrations play a most important part, Mr. Tesla having succeeded in obtaining more perfect control of the more rapid vibrations of light waves. Carbon is not employed as the light giver. As to the nature of the force employed the interviewer quotes Mr. Tesla as saying that he "will form an electric circuit and then with a file reduce the thickness of the wire a sixteenth of an inch and double the force of the current." The details of Mr. Tesla's work in this direction are unfortunately lacking, but Mr. Tesla promises to prepare a paper on the subject, "which he will read presently to a few scientific friends." Failing full details the information thus far vouchsafed is insufficient to permit of much comment, but we are glad to know that we may so soon expect a promised advance in electric lighting. All such work as this, or, in older directions, such as that on the Nernst lamp, is worthy of fullest encouragement.

The New York Tribune March 3, 1899

NIKOLA TESLA'S EXPERIMENTS.

DESCRIPTION OF HIS TRANSMITTING ELECTRICAL ENERGY WITHOUT WIRES.

The current issue of "The Electrical Review" contains the first extended description published of experiments carried on in Nikola Tesla's laboratory, and demonstrating, it is stated, his recently announced discoveries in the application of electricity to commercial purposes without the use of conducting wires. The experiments involve handling currents up to eight millions of volts, produced by his perfected oscillators with entire safety, it is said. Photographs of the experiments make it appear that the energy can be transmitted to any point desired. In one illustration the inventor appears to receive the electrical waves from a distance and to develop a pressure of 500,000 volts in a coil which he holds in his hand, preserving himself against injury by maintaining a fixed position, where the pressure developed is small. Another photograph shows an assistant receiving in his body the currents from an electrical oscillator, which pass through his body and make a metal bar glow in his hands, also lighting a vacuum tube on the ceiling.

In closing his communication to "The Electrical Review," Mr. Tesla says:

To the scientific experts, who are familiar, in theory and experiment, with electrical vibrations, the results here shown will, I believe, speak in eloquent language. But those readers to whom they are naturally less intelligible will ask: What are they good for, and what do they or have they demonstrated? To them it may be said that they have shown and proved among many other things: That ordinary currents can be transformed with high economy into electrical vibrations of any pitch, which are needed in many novel arts; they have shown that electrical energy in great amounts can be efficiently and safely transmitted without the use of wires to any point of the globe, however distant; they have furnished proof that the movements and operation of bodies and machinery carried by the same can be controlled from a great distance without any tangible connection whatever and with absolute precision; they have proved the practicability of a system of signalling without wires, not with the imperfect appliances as before attempted, which cannot be tuned, and are rendered useless by the play of a small induction coil, but by means of apparatus producing powerful oscillations and circuits in exact synchronism, with which it is impossible to interfere; they have shown that atmospheric nitrogen can be readily combined and valuable products manufactured, merely by the application of cheap water power, and that light, diffusive, like that of the sun, can be produced with an economy greater than is obtainable in the usual ways, and with lamps that never consume.

"The Electrical Review," in its editorial comment, says:

The experiments on which Tesla dwells, and which are evidently the result of years of patient labor, are, in our opinion, the most striking and promising that have been shown in years, and they cannot fail to create a profound impression on scientific minds.

The Reichsgericht, of Germany, has confirmed the decision of the lower courts declaring the Tesla polyphase motor patents invalid. The court reviewing the case holds that the patents are void, owing to their not having been worked according to the requirements of the German patent law. The court goes on to say, however, that even if the patent had been sustained on that ground, it would have been, nevertheless, invalidated, owing to the fact that the invention was not adequately described in the German patent specification, whereas the American patent specification is clear. It is understood, says The Electrical Engineer, of New York, that the Helios Company, of Cologne, who control the Tesla patents in Germany, will no longer contest the suits which it has brought against several parties in Germany.

TESLA ON CURRENT INTERRUPTERS.

To the Editor of Electrical Review:

I wish to acknowledge the receipt of your favor of March 11, and thank you for calling my attention to the matter of the "electrolytic current interrupter." Pressing work has for the past few weeks claimed all my time, and I have been unable to peruse the technical periodicals; and it is only a few days ago that I noticed an article descriptive of the device. Upon receiving your note I have gone over the journals and have read the articles and comments that have appeared. Most of them are indicative of time ill-spent for the purpose of comprehending the requirements of such an apparatus.

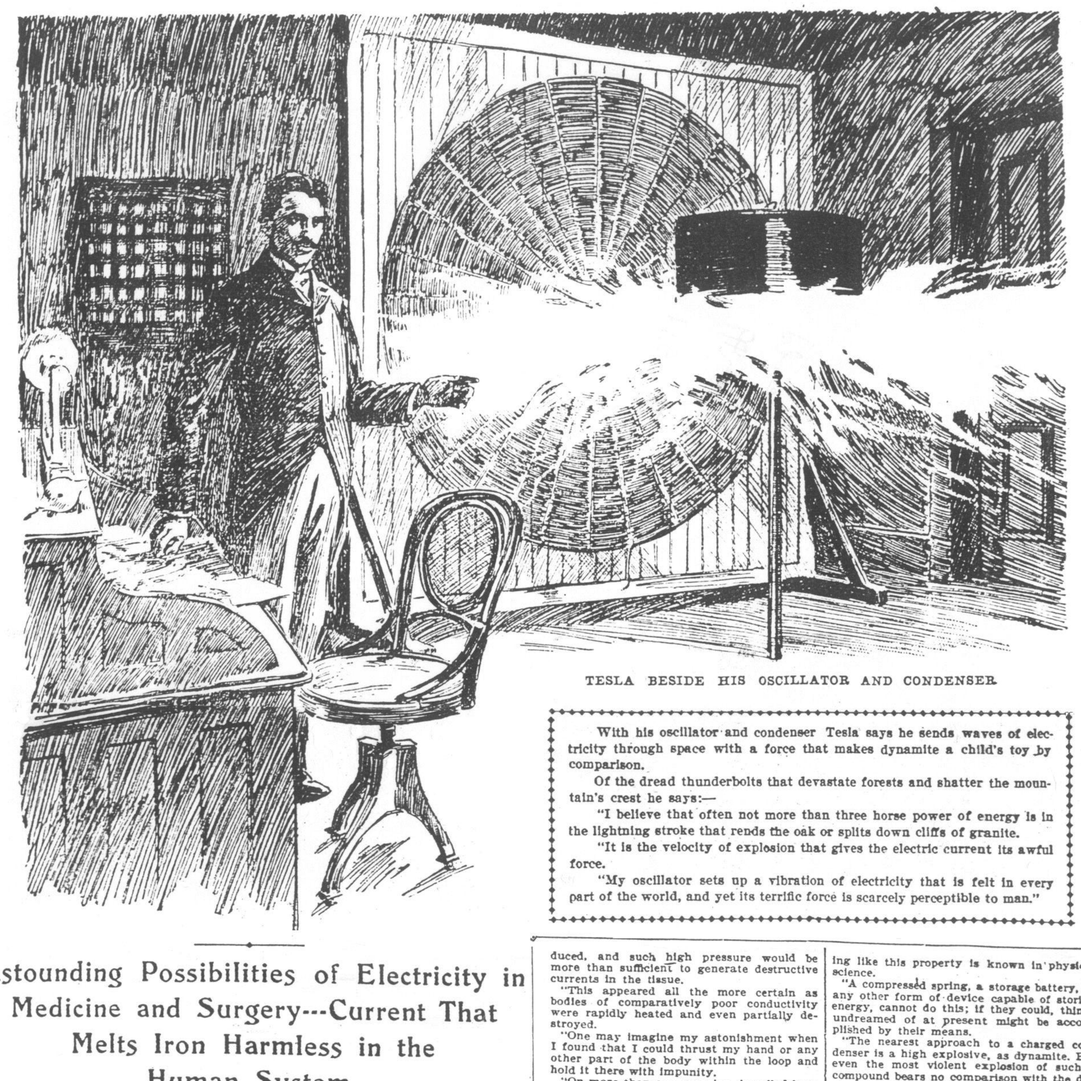
To stimulate the ardor of the zealous experimenters, who believe in the revolutionary character of this discovery, it might be well to suggest one or two such simple devices for interrupting the current For instance, a very primitive contrivance of this kind comprises a poker—yes, an ordinary poker, connected by means of a flexible cable to one of the mains of the generator, and a bathtub filled with conducting fluid which is connected in any suitable manner, through the primary of an induction coil, to the other pole of the generator. When the experimenter desires to take a Roentgen picture, he brings the end of the poker to white heat, and, thrusting the same into the bathtub, he will at once witness an astonishing phenomenon, the seething and boiling liquid making and breaking the current in rapid succession, and the powerful rays generated will at once convince him of the great practical value of this discovery. I might further suggest that the poker may be conveniently heated by means of a welding machine.

Another device, entirely automatic, and probably suitable for use in suburban districts, comprises two insulated metal plates, supported in any convenient manner, in close proximity to each other. These plates are connected through the primary of an induction coil with the terminals of a generator, and are bridged by two movable contacts joined by a flexible cable. The two contacts are both attached to the legs of a good-sized chicken standing astride on the plates. Heat being applied to the latter, muscular contractions are produced in the legs of the chicken, which thus makes and breaks the current through the induction coil. Any number of such chickens may be provided and the contacts connected in series or multiple arc, as may be desired, thus increasing the frequency of the impulses. In this manner fierce sparks, suitable for most purposes, may be obtained, and vacuum tubes may be operated, and these contrivances will be found a notable improvement on certain circuit-breakers of old, with which two enterprising editors undertook some years ago to revolutionize the systems of electric lighting. The enterprising editors are wiser now. They are to be congratulated, and their readers, scientific societies and the profession, all ought to be congratulated, and—"all is well that ends well." The observant experimenter will not fail to note that the fierce sparks frighten the chickens, which are thus put into more violent spasms and muscular contractions, this again increasing the fierceness of the sparks, which, in return, causes a greater fright of the chickens and increased speed of interruptions; it is, in fact, as Kipling says:

"Interdependence absolute, foreseen, ordained, decreed.
To work, ye'll note, at any tilt an' every rate o' speed."

But to return, in all earnestness, to the "electrolytic interrupter" described, this is a device with which I am perfectly familiar, having carried on extensive experiments with the same two or three years ago. It was one of many devices which I invented in my efforts to produce an economical contrivance of this kind. The name is really not appropriate, inasmuch as any fluid, either conducting or made so in any manner, as by being rendered acid or alkaline, or by being heated, may be used. I have even found it possible, under certain conditions, to operate with mercury. The device is extremely simple, but the great waste of energy attendant upon its operation and certain other defects make it entirely unsuitable for any valuable, practical purpose, and as far as those instances are concerned, in which a small amount of energy is needed, much better results are obtained by a properly designed mechanical circuit-breaker. The experimenters are very likely deceived by finding that an induction coil gives longer sparks when this device is inserted in place of the ordinary break, but this is due merely to the fact that the break is not properly designed. Of the total energy supplied from the mains, scarcely one-fourth is obtainable of that amount, which a well constructed mechanical break furnishes in the secondary, and although I have designed many improved forms, I have found it impossible to increase materially the economy. Two improvements, however, which I found at that time necessary to introduce, I may mention for the benefit of those who are using the device. As will be readily noted, the small terminal is surrounded by a gaseous bubble, in which the makes and breaks are formed, generally in an irregular manner, by the liquid being driven towards the terminal at some point. The force which drives the liquid is evidently the pressure of the fluid column, and by increasing the fluid pressure in any manner the liquid is forced with greater speed towards the terminal and thus the frequency is increased. Another necessary improvement was to make a provision for preventing the acid or alkali from being carried off into the atmosphere, which always happens more or less, even if the liquid column be of some height. During my early experiments with the device I became so interested in it that I neglected this precaution, and I noted that the acid had attacked all the apparatus in my laboratory. The experimenter will conveniently carry out both of these improvements by taking a long glass tube of, say, six to eight feet in length, and arranging the interrupting device close to the bottom of the tube, with an outlet for eventually replacing the liquid. The high column will prevent the fumes from vitiating the atmosphere of the room, and the increased pressure will add materially to the effectiveness of the performance. If the liquid column be, say, nine times as high, the force driving the fluid towards the contact is nine times as great, and this force is capable, under the same conditions, of driving the fluid three times as fast, hence the frequency is increased in that ratio and, in fact, in a somewhat greater ratio, as the gaseous bubble, being compressed, is rendered smaller, and therefore the liquid is made to travel through a smaller distance. The electrode, of course, should be very small to insure the regularity of operation, and it is not necessary to use platinum. The pressure may, however, be increased in other ways, and I have obtained some results of interest in experiments of this kind.

As before stated, the device is very wasteful, and, while it may be used in in which by far better results are obtainable with devices equally simple, if not more so. I may mention one here, based on a different principle, which is incomparably more effective, more efficient and also simpler on the whole. It comprises a fine stream of conducting fluid which is made to issue, with any desired speed, from an orifice connected with one pole of a generator, through the primary of the induction coil, against the other terminal of the generator placed at a small distance. This device gives discharges of a remarkable suddenness, and the frequency may be brought within reasonable limits, almost to anything desired. I have used this device for a long time in connection with ordinary coils and in a form of my own coil with results greatly superior in every respect to those obtainable with the form of device discussed.



If time permits I shall, in compliance with the request expressed in your letter, make a few statements referring to such make and break devices in general, and various forms based on this new principle.

Yours very truly,

N. Tesla.

New York, March 13.

TESLA'S LIGHTNING TO FREE MAN FROM DISEASE.

TESLA BESIDE HIS OSCILLATOR AND CONDENSER.

With his oscillator and condenser Tesla says he sends waves of electricity through space with a force that makes dynamite a child's toy by comparison.

Of the dread thunderbolts that devastate forests and shatter the mountain's crest he says:—

"I believe that often not more than three horse power of energy is in the lightning stroke that rends the oak or splits down cliffs of granite.

"It is the velocity of explosion that gives the electric current its awful force.

"My oscillator sets up a vibration of electricity that is felt in every part of the world, and yet its terrific force is scarcely perceptible to man."

Astounding Possibilities of Electricity in Medicine and Surgery---Current That Melts Iron Harmless in the Human System.

HOW to use tremendous electrical forces, freeing us from microbes and disease," is the latest marvel of science.

Tesla has made some astonishing discoveries. He is able to shoot millions and tens of millions of volts of real thunder storm lightning through a man, that will melt glass and fuse metals, and yet give him no injury or pain.

More wonderful still is that all this mighty force which a human being can withstand will destroy microbic life and disease germs within, making one's system as clean and sweet as atmosphere after a thunder storm.

In view of these facts electro-medical scientists have shown great interest in Tesla's experiments with his machines for generating electricity that welds iron, tears steel bars to fragments, and yet plays harmlessly through the human system, creating new health and life for the microbe poisoned victim.

Tesla Rushing His Inventions.

A remarkable feature of it all is that Tesla has no patents to sell for manufacturing medicinal lightning, and he has no agents selling his all healing volts to the public.

He is working on a far loftier plane of achievement. He is pushing to completion his startling inventions for propelling and steering torpedo boats, war ships or any other kind of craft at a distance from land, with no person on board nor any connection by wire. He is also perfecting his machine for transmitting power from Niagara Falls to Paris or any other part of the world without a wire, by means of his electro-automatic instruments—each in perfect sympathy and unison with the other, so that electric currents leap across the intervening space of one or many thousands of miles.

Tesla's marvellous problems have now been solved, it is said, and he has only to perfect the necessary appliances to present them to the world in practical working form.

To this end a double force of skilled men are now engaged and the machines are being pushed with unceasing rapidity to completion.

Among the many discoveries made by Tesla none is more impressive than the fact that with a small volume of electricity he secures tremendous results.

How is it done?

By the velocity of the electrical explosions in his marvellous machine known as the condenser.

What giant can drive a hard wax candle into wood with blows from a hammer? But a boy can shoot a soft tallow dip through an oak plank with a shotgun. The powder gives the candle velocity.

A frontier teamster can split a board with his ox whip, which his child plays with and finds harmless. Sand blown from a powerful air blast machine cuts glass and steel like butter. Big steel rails are cut with a soft iron disc.

With the water that falls in gentle dew on the rose garden, the hydraulic miner in California beats down hills and mountains, because of the force—velocity—behind the water.

With his oscillator and condenser, Tesla says he sends waves of electricity through space with a force that makes dynamite a child's toy by comparison.

Of the dread thunderbolts that devastate forests and shatter the mountain's crest he says:—

"I believe that often not more than three horse power of energy is in the lightning stroke that rends the oak or splits down cliffs of granite. It is the velocity of explosion that gives the electric current its awful force.

"My oscillator sets up a vibration of electricity that is felt in every part of the world, and yet its terrific force is scarcely perceptible to man."

Tesla has been criticised severely by unthinking scientists, yet his invention of the "rotating magnetic field motor" has made those mighty machines at Niagara Falls possible. They light the city of Buffalo, twenty miles away, and run its street cars and the machinery of a thousand factories. Tesla's name in big letters of bronze cast on the plates of these world famed machines is a fitting monument to his genius.

His achievement in obtaining instantaneous force encircling the globe, omnipotent and everywhere present, borders on the miraculous—the infinite.

Tesla makes the unseen a visible, terrible manifestation in nature. He generates currents that would not disturb a fly on your sleeping babe, yet they are as devastating as a cyclone. He gives the faintest whispering current force—a force that disintegrates armor plate as quickly as you melt sugar with water.

In a way, he brings certainty out of chaos. He makes substance from "nothing." That which you can neither see, taste, hear nor smell, he lashes into a storm of fury, and you hear this "nothing" roar and thunder like Niagara.

It suggests to the contemplative mind that period when this great rolling globe of ours was "without form and void."

It suggests the phenomena of the original creation of matter made visible to man—the power of making substance out of thought. Of thinking "nothing" into substance, and perhaps the life principle itself. In this direction, toward this great end, science seems certainly drifting.

In one sense it may be said that the only sure thing to-day, the only thing that can be predicted with unfailing accuracy, is that which no man has seen with his naked eye nor touched, nor heard, nor tasted with his lips—the star which no one has beheld, but which science has already catalogued and which will appear next year or next century to the hour and minute.

Who dares stake his life on the sure arrival of to-morrow's five o'clock express at that hour? Yet all the world knows that to-morrow's eclipse will arrive on time to the second.

Working Toward Infinite Possibilities.

It is along these omnipotent, infallible lines of science that Tesla is apparently working.

Now to go back to his views on the use of electricity for disease.

Tesla has been before the highest scientific body of its kind in the country with his discovery. His address to the Electro-Therapeutic Association regarding the use of electricity by physicians in healing wounds and curing disease is soon to be published by the society.

In his carefully prepared paper he makes these interesting statements:—"The body of a person may be subjected without danger to electrical pressures vastly in excess of any producible by ordinary apparatus, for they may amount to several million volts, as has been shown in actual practice.

"Now, when a conducting body is electrified to go high a degree small particles, which may be adhering firmly to its surface, are torn off with violence and thrown to distances which can only be conjectured.

"The continuous improvement of the instruments and the study of the phenomenon may shortly lead to the establishment of a novel mode of hygienic treatment which would permit an instantaneous cleaning of the skin of a person, simply by connecting the same to, or possibly, by merely placing the person in the vicinity of, a source of intense electrical oscillations, this having the effect of throwing off, in a twinkle of the eye, dust or particles of any extraneous matter adhering to the body."

Of his experiments Tesla says:—

"Soon my efforts were centred upon producing in a small space the most intense inductive action, and by gradual improvement in the apparatus I obtained results of a surprising character.

"For instance, when the end of a heavy bar of iron was thrust within a loop powerfully energized, a few moments were sufficient to raise the bar to a high temperature.

Wonders of His Electricity.

"Even heavy lumps of other metals were heated as rapidly as though they were placed in a furnace.

"When a continuous band formed of a sheet of tin was thrust into the loop the metal was fused instantly, the action being comparable to an explosion, and no wonder, for the frictional losses accumulated in it at the rate of possibly ten horse power.

"Masses of poorly conducting material behaved similarly, and when a highly exhausted bulb was pushed into the loop the glass was heated in a few seconds nearly to the point of melting.

"When I first observed these astonishing actions I was interested to study their effects upon living tissues.

"As may be assumed, I proceeded with all the necessary caution, and well I might, for I had the evidence that in a turn of only a few inches in diameter an electromotive force of more than ten thousand volts was produced, and such high pressure would be more than sufficient to generate destructive currents in the tissue.

"This appeared all the more certain as bodies of comparatively poor conductivity were rapidly heated and even partially destroyed.

"One may imagine my astonishment when I found that I could thrust my hand or any other part of the body within the loop and hold it there with impunity.

"On more than one occasion, impelled by a desire to make some novel and useful observation, I have willingly or unconsciously performed an experiment connected with some risk, this being scarcely avoidable in laboratory experience.

"Now, why is it that in a space in which such violent turmoil is going on living tissue remains uninjured?

"One might say the currents cannot pass because of the great self-induction offered by the large conducting mass. But this it cannot be, because a mass of metal offers a still higher self-induction and is heated just the same.

"One might argue the tissues offer too great a resistance. But this, again, cannot be the reason, for all evidence shows that the tissues conduct well enough, and besides, bodies of approximately the same resistance are raised to a high temperature.

"One might attribute the apparent harmlessness of the oscillations to the high specific heat of the tissue, but even a rough quantitative estimate from experiments with other bodies shows that this view is untenable.

Human Tissues Are "Condensers."

"The only plausible explanation I have so far found is that the tissues are condensers. This only can account for the absence of injurious effects.

"But it is remarkable that, as soon as a heterogeneous circuit is constituted, as by taking in the hands a bar of metal and forming a closed loop in this manner, the passage of the currents through the arms is felt, and other physiological effects are distinctly noted.

"The strongest action is, of course, secured when the exciting loop makes only one turn, unless the connections take up a considerable portion of the total length of the circuit, in which case the experimenter should settle upon the least number of turns by carefully estimating what he loses by increasing the number of turns, and what he gains by utilizing thus a greater proportion of the total length of the circuit.

"It should be borne in mind that when the exciting coil has a considerable number of turns and is of some length, the effects of electrostatic induction may preponderate, as there may exist a very great difference of potential—a hundred thousand volts or more—between the first and last turn. However, these latter effects are always present even when a single turn is employed.

"When a person is placed within such a loop any pieces of metal, though of small bulk, are perceptibly warmed. Without doubt they would be also heated—particularly if they were of iron—when imbedded in living tissue, and this suggests the possibility of surgical treatment by this method.

To Sterilize Wounds Possible.

"It might be possible to sterilize wounds, or to locate, or even to extract metallic objects, or to perform other operations of this kind within the sphere of the surgeon's duties in this novel manner.

"Most of the results enumerated, and many others still more remarkable, are made possible only by utilizing the discharges of a condenser.

"It is probable that but a very few—even among those who are working in these identical fields—fully appreciate what a wonderful instrument such a condenser is in reality. Let me convey an idea to this effect.

"One may take a condenser, small enough to go in one's vest pocket, and by skilfully using it he may create an electrical pressure vastly in excess—a hundred times greater, if necessary—than any producible by the largest static machine ever constructed.

"Or he may take the same condenser, and, using it in a different way, he may obtain from it currents against which those of the most powerful welding machine are utterly insignificant.

"Or, again, he may avail himself of the same marvellous instrument, and, by suddenly discharging its stored electricity, he may create such a terrific commotion in the space that, though silent and invisible, it can be detected, as actually demonstrated, at distances much greater than those at which the sound of the largest gun is perceptible, distances which are measured in tens, perhaps hundreds, and even thousands, of miles.

"Those who are imbued with popular notions as to the pressures of static machines and currents obtainable with a commercial transformer will be astonished at this statement—yet the truth of it is easy to see.

His Method of Storing Electrical Force.

"Such results are obtainable, and easily, because the condenser can discharge the stored energy in an inconceivably short time. Nothing like this property is known in physical science.

"A compressed spring, a storage battery, or any other form of device capable of storing energy, cannot do this; if they could, things undreamed of at present might be accomplished by their means.

"The nearest approach to a charged condenser is a high explosive, as dynamite. But even the most violent explosion of such a compound bears no comparison with the discharge or explosion of a condenser.

"For, while the pressures that are produced in the detonation of a chemical compound are measured in tens of tons per square inch, those which may be caused by condenser discharges may amount to thousands of tons per square inch, and if a chemical could be made which would explode as quickly as a condenser can be discharged under conditions which are realizable an ounce of it would quite certainly be sufficient to render useless the largest battle ship.

"That important realizations would follow from the use of an instrument possessing such ideal properties I have been convinced since long ago, but I also recognized early that great difficulties would have to be overcome before it could replace less perfect implements now used in the arts for the manifold transformations of electrical energy.

"These difficulties were many. The condensers themselves, as usually manufactured, were inefficient, the conductors wasteful, the best insulation inadequate, and the conditions for the most efficient conversion were hard to adjust and to maintain.

Problem of Controlling Electricity.

"One difficulty, however, which was more serious than others, and to which I called attention when I first described this system of energy transformation, was found in the devices necessarily used for controlling the charges and discharges of the condenser.

"They were wanting in efficiency and reliability, and threatened to prove a decided drawback, greatly restricting the use of the system and depriving it of many valuable features.

"For a number of years I have tried to master this difficulty. During this time a great number of such devices were experimented upon. Many of them promised well at first, only to prove inadequate in the end.

"Reluctantly, I came back upon an idea on which I had worked long before. It was to replace the ordinary brushes and commutator segments by fluid contacts. I had encountered difficulties then, but the intervening years in the laboratory were not spent in vain, and I made headway.

"First it was necessary to provide for a circulation of the fluid, but forcing it through by a pump proved itself impractical.

"Then the happy idea, presented itself to make the pumping device an integral part of the circuit interrupter, enclosing both in a receptacle to prevent oxidation.

"Next some simple ways of maintaining the circulation, as by rotating a body of mercury, presented themselves. Then I learned how to reduce the wear and losses which still existed. I fear that these statements, indicating how much effort was spent in these seemingly insignificant details, will not convey a high idea of my ability, but I confess that my patience was taxed to the utmost.

Success for the Physician of Science.

Finally, though, I had the satisfaction of producing devices which are simple and reliable in their operation, which require practically no attention, and which are capable of effecting a transformation of considerable amounts of energy with fair economy.

"The physician will not be able to obtain an instrument suitable to fulfil many requirements. He will be able to use it in electro-therapeutic treatment in most of the ways enumerated. He will have the facility of providing himself with coils such as he may desire to have for any particular purpose, which will give him any current or any pressure he may wish to obtain.

"Such coils will consist of but a few turns of wire, and the expense of preparing them will be quite insignificant.

"The instrument will also enable him to generate Rönigen rays of much greater power than obtainable with ordinary apparatus.

"A tube must still be furnished by the manufacturers which will not deteriorate, and which will allow to concentrate larger amounts of energy upon the electrodes.

"When this is done nothing will stand in the way of an extensive and efficient application of this beautiful discovery, which must ultimately prove itself of the highest value, not only at the hands of the surgeon, but also of the electrotherapist, and, what is most important, of the bacteriologist."

"The first and simplest method of applying the currents was to connect the body of the patient to two points of the generator, be it a dynamo or an induction coil. The alternator may be one giving from five to ten thousand complete vibrations per second, this number being still within the limit of practicability.

WESTINGHOUSE SUES GENERAL ELECTRIC ON THE TESLA PATENTS.

The following important information is received by the ELECTRICAL REVIEW just as it goes to press. It would indicate that some new features have entered into the big electric lighting deal in New York city. There is also a rumor that this is an entering wedge in the split that is said to be likely to come between the General Electric and Westinghouse interests in the matter of their patent agreement. The electrical field will view with much interest and concern this new move. The statement the ELECTRICAL REVIEW has received is as follows:

The suit referred to in your inquiry is doubtless the suit which the Westinghouse company has instituted in the Circuit Court of the United States for the Northern District of New York, to enjoin the General Electric Company from delivering multiphase apparatus covered by the Tesla patents to the Edison Electric Illuminating Company of New York. The suit is brought under the agreement relating to patents which the General Electric and Westinghouse companies entered into in March, 1896, and the Westinghouse company contends that the apparatus in question can not be delivered by the General Electric Company to the New York Edison company because of the exclusive license under the Tesla patents which the Westinghouse Company's licensee in New York city, the United Electric Light and Power Company, has held for many years. The bill was filed at Utica, Tuesday, March 21, and the motion for a preliminary injunction is returnable Tuesday, April 4.

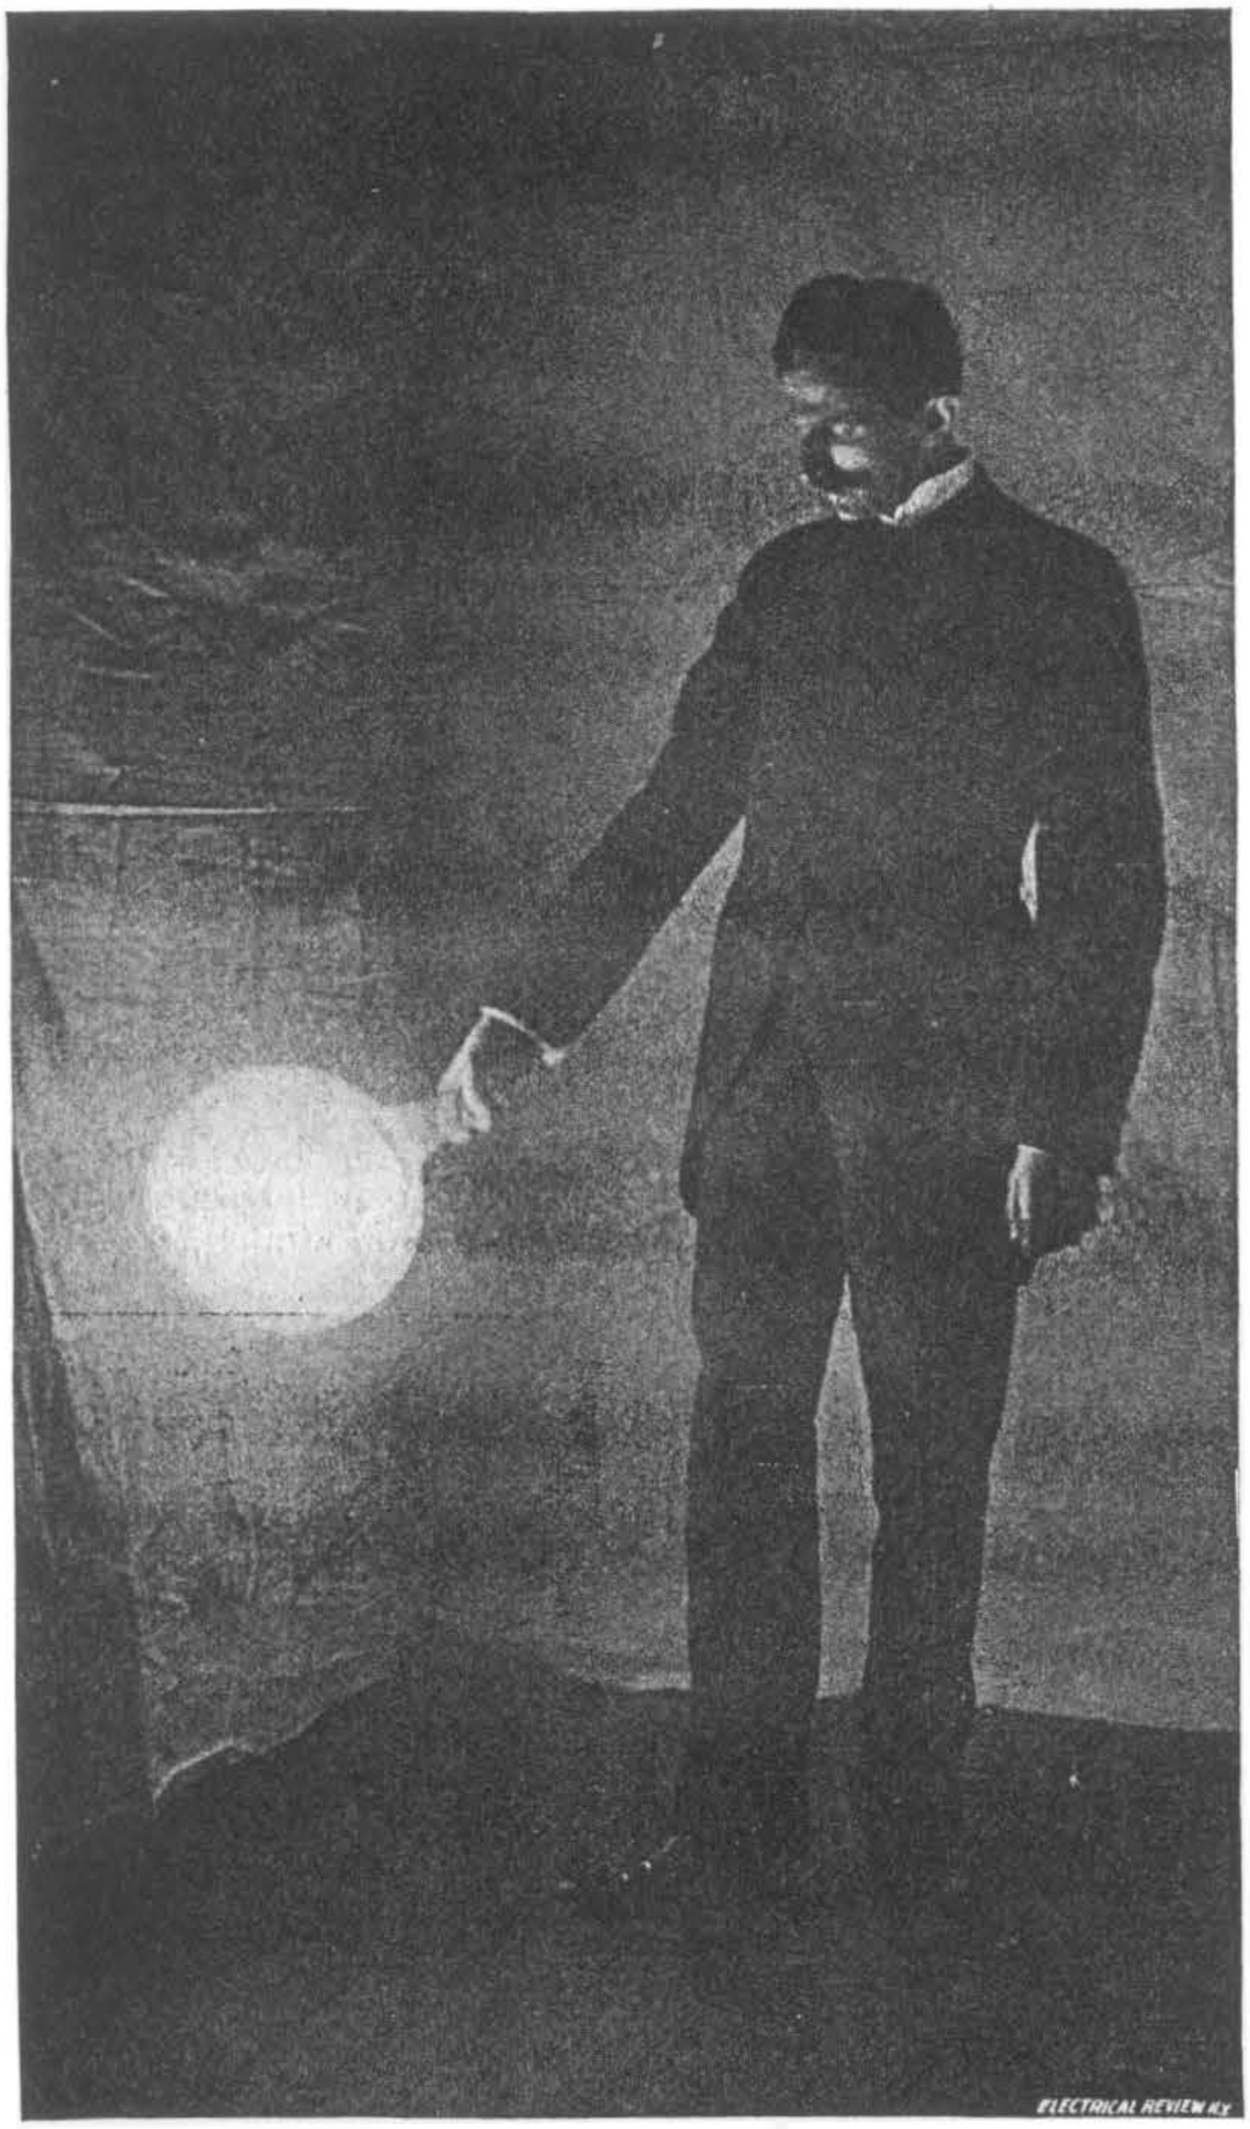

FIG. 1.—"SOME EXPERIMENTS IN TESLA'S LABORATORY WITH CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY"—LIGHTING A DISCONNECTED VACUUM BULB OF 1,500 CANDLE-POWER BY HIGH-FREQUENCY CURRENTS—PHOTOGRAPH TAKEN BY THE LIGHT OF THE BULB ITSELF, EXPOSURE ABOUT TWO SECONDS.

SOME EXPERIMENTS IN TESLA'S LABORATORY WITH CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY.

TO THE EDITOR OF ELECTRICAL REVIEW:

Since the unfortunate accident of four years ago, which crippled and delayed my labors in a number of lines so seriously, I have had but little time to devote to the fulfillment of a duty which, next to that of turning his best efforts to diligent inquiry in the fields he has chosen, is the most important to a scientific man; namely, that of giving an exact record of the results obtained. I realize with sorrow every day that, despite of all pains taken to this end, I am gaining but very slowly on the material accumulated. Ideas come through a happy inspiration, apparently without much exertion, but it is the working out of the many harassing details and putting into a presentable form which consumes time and energy. It was impossible to abandon research in new directions, in which I have felt myself irresistibly drawn, and it was equally impossible to do full justice to the work partially completed, and I can only hope to gradually retrieve my losses by the only expedient available, which is to redouble the zeal. It is not the best plan to follow, I confess, and is in radical opposition to the kindly advice given to me by a great philosopher, but this admission may serve to refute the statements attributed to me to the effect that I intended to live 200 years by sleeping most of the time! It may also show that it is not this mode of life which is responsible for the delay in the commercial introduction of my system of vacuum tube lighting, as has been asserted by some people who have found a singular satisfaction in dwelling extensively in their columns on my proposed glass house on Long Island, which was to cover acres of ground, and which was to be built for the purpose of catching the sun's rays; on my claims of the discoveries

of Roentgen; on my invention enabling me to move and explode torpedo boats by will power, and on my efforts to annihilate the entire British navy. It is to be hoped that the limit of patience of the readers has been finally reached.

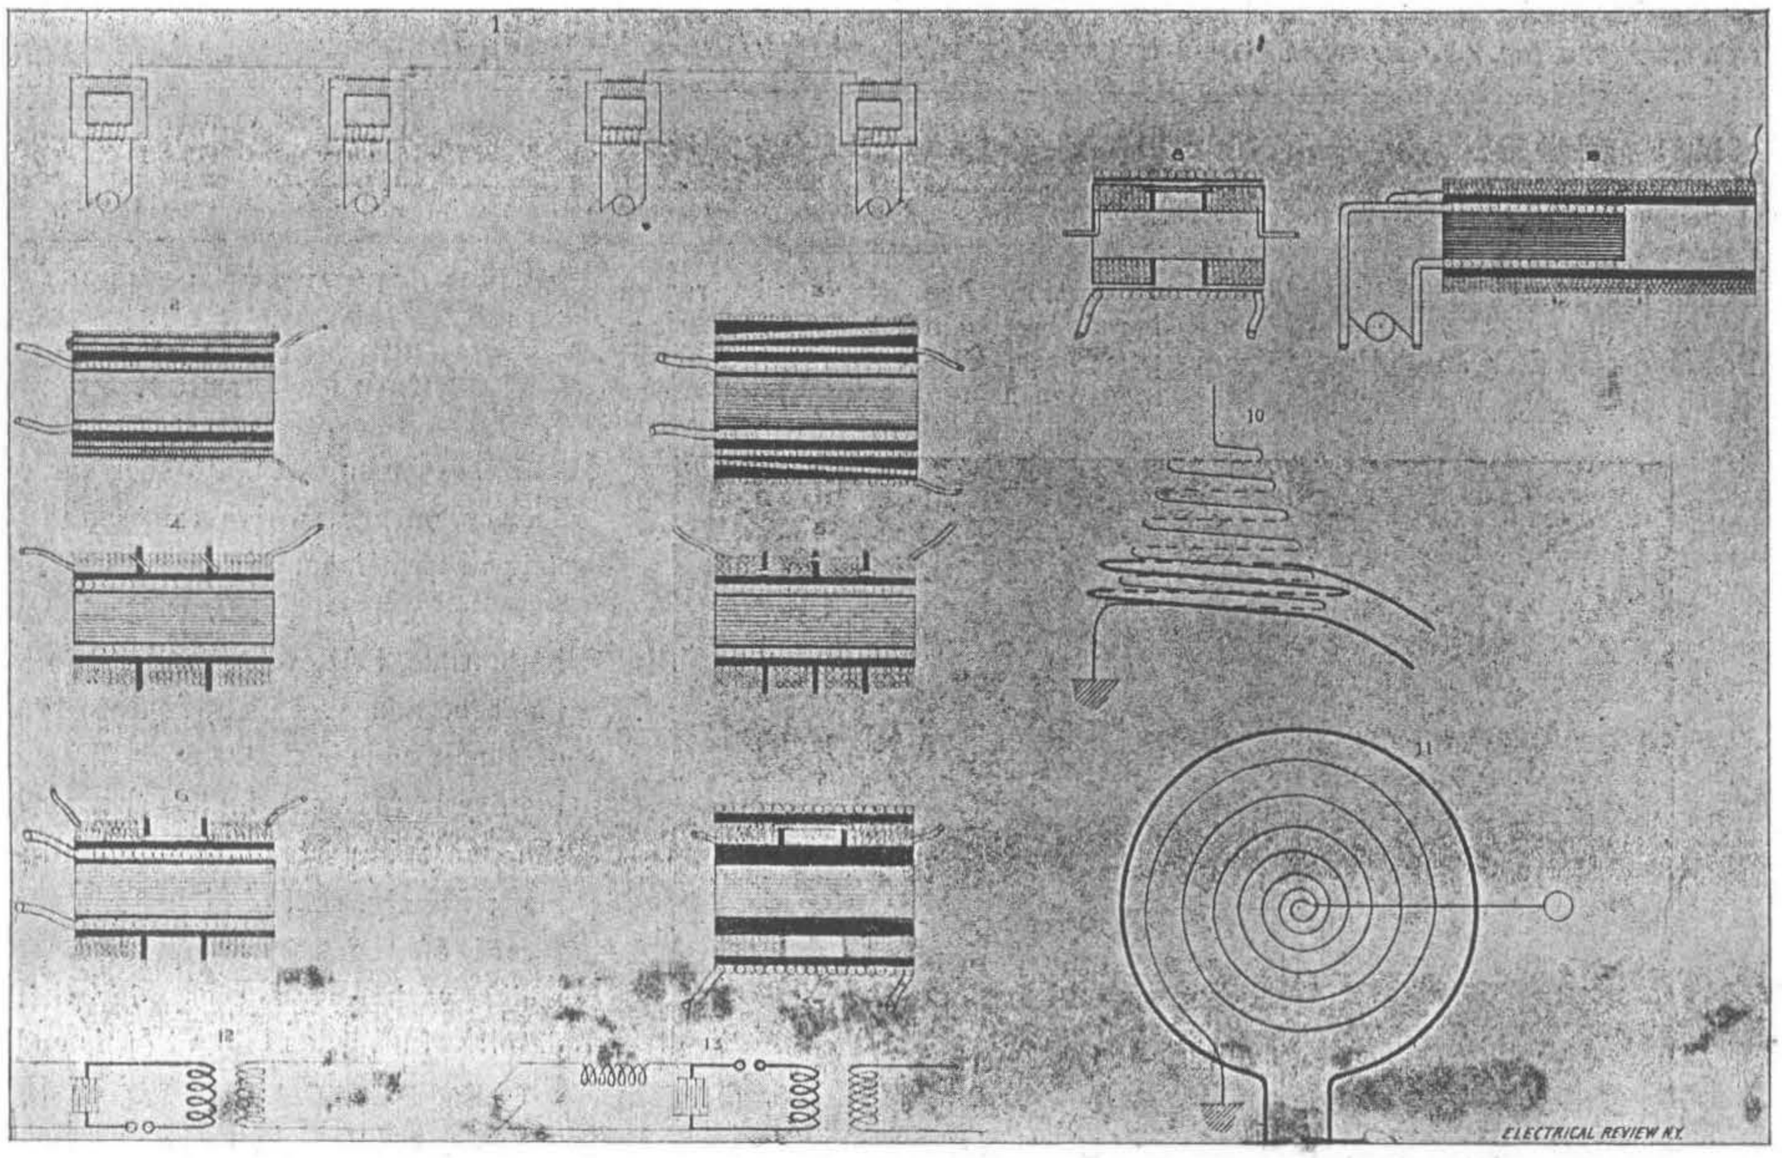

FIG. 2.—"SOME EXPERIMENTS IN TESLA'S LABORATORY WITH CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY."—TABLE OF DIAGRAMS ILLUSTRATING THE EVOLUTION OF A HIGH-TENSION TRANSFORMER ENABLING THE PRODUCTION OF ELECTRO-MOTIVE FORCES OF MANY MILLIONS OF VOLTS.

At that time, still painfully remembered, my energies were taken up principally by some mechanical problems of great importance, and the few observations in electricity which I was fortunate to make came like ever so many refreshing berries found on the road by a weary wanderer. The journey is not finished yet, and the wanderer is well-nigh exhausted. He longs for more sweet berries, and anxiously asks, "Did any one pass this road before?"

It was chiefly in three directions that electrical investigation was attractive and promising: There were the excessive electrical pressures of millions of volts, which opened up wonderful possibilities if producible in practical ways; there were the currents of many hundreds of thousands of amperes, which appealed to the imagination by their astonishing effects, and, most interesting and inviting of all, there were the powerful electrical vibrations with their mysterious actions at a distance. What better work could one do than inventing methods and devising means for enabling scientific men to push investigation far out into these practically unknown regions? This work was difficult and tedious and involved a certain amount of material sacrifice, but promised a higher reward if successfully accomplished—the gratitude of those many who exercise their gifts in different directions and are compelled to rely on the expert for providing them with implements suitable for their special purpose. Who can estimate how much science has been advanced by the beautiful instruments of measure which Lord Kelvin has given us? Unfortunately, in many of the new fields such instruments are yet to be invented. Still more unfortunately, information seems to be more needful than instruments, if one is to judge from statements frequently made in technical periodicals on a variety of subjects. An experimenter, for instance, measures the current through a make-and-break device, and, finding it small, he infers that the conversion is economical. Another suggests to determine the efficiency of conversion through such a device by the calorimetric method. Now, as a matter of fact, if there was such a contrivance, absolutely perfect in its action, which would behave as I have explained on another occasion, and change the resistance of a gap from zero to infinity without any loss in the gap itself, which separates the terminals, it still might happen that 99 per cent of the energy supplied to the circuit would be wasted in radiations, useless for the purpose contemplated. The calorimetric method would in this, or generally in any other instance, in which the disturbances produced are very sudden, entirely fail in giving an approximation as to the energy dissipated in the circuit, for the simple reason that the friction encountered by a wave in its passage through a medium, which determines the amount of heat generated, is no measure whatever of the energy of the wave. Thus, certain well understood cases excepted, the only method at present available in such estimates is to take account of the energy consumed by the source of supply. This remark alone will show that the economical conversion of currents by make and break devices is a much more difficult problem than it appears to those who have studied it superficially. Not only must the devices used in the transformation possess certain characteristics, but the entire circuit must be properly designed. One can not help admiring the confidence and self-possession of experimenters, who put

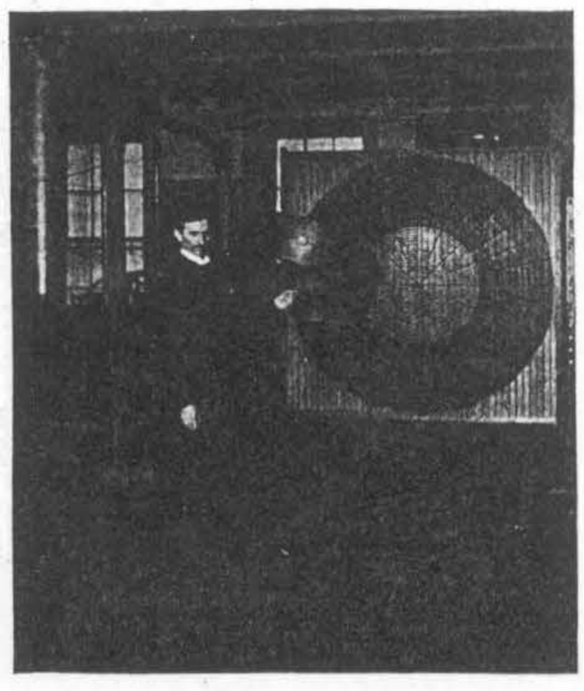

FIG. 5.—PHOTOGRAPH SHOWING AN INCANDESCENT LAMP LIGHTED BY MEANS OF WAVES TRANSMITTED THROUGH SPACE TO A COIL SYNCHRONIZED WITHOUT A CONDENSER.

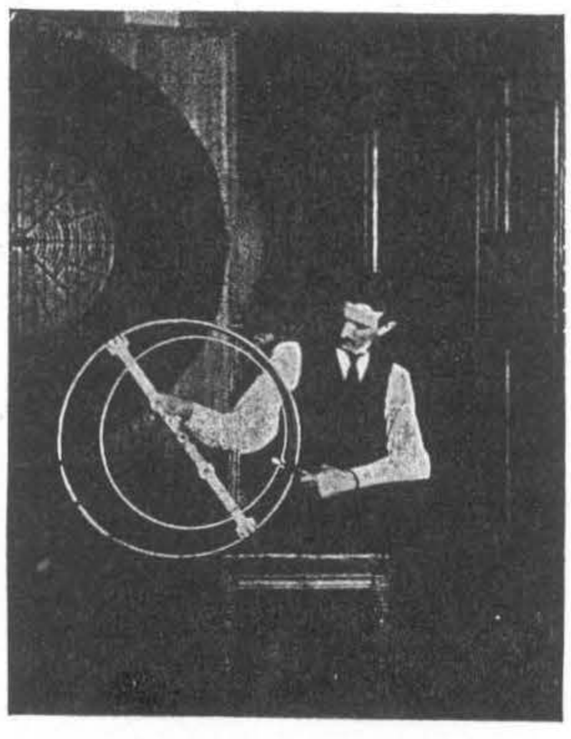

FIG. 6.—EXPERIMENT ILLUSTRATING THE ACTION OF A SYNCHRONIZED CIRCUIT ENERGIZED BY WAVES TRANSMITTED FROM A DISTANT OSCILLATOR — THE ENERGY RECEIVED IS TRANSFERRED UPON ANOTHER UNRESPONSIVE CIRCUIT, LIGHTING THE INCANDESCENT LAMP ATTACHED TO THE SAME.

forth carelessly such views and who, with but a few days', not to say hours', experience with a device, venture before scientific societies, apparently unmindful of the responsibility of such a step, and advance their imperfect results and opinions hastily formed. The sparks may be long and brilliant, the display interesting to witness, and the audience may be delighted, but one must doubt the value of such demonstrations. There is so little novelty in them, that one might easily perform a practical joke on the lecturer by describing in advance all his drawings, apparatus, experiments and theories, thus placing him in an awful predicament. Though such a course would be naturally impolite, it might be found justified and excused by the circumstances, for premature expressions of opinion and demonstrations of this kind are responsible for much evil, one of these being the erroneous idea which they create in scientific circles as to the importance of an advance made. It grieves one to observe that, for example, such great work as that of Professor Dewar, which he turns out with clock regularity, is scarcely commented upon in the technical columns, whereas a worthless trap for interrupting currents, which usually consumes nine-tenths of the energy, and is, besides, useless for other reasons, and just suitable for the amusement of small boys, who are beginning their electrical experience with Leclanche batteries and $1.50 induction coils, is hailed as an important scientific discovery. An agreeable contrast is afforded by those few who patiently investigate, contented to lose the credit for advances made rather than to present them to the world in an imperfect state, who form their opinions conscientiously, after a long and careful study, and have little to correct afterward.

The importance of the task of providing proper implements for research in these various fields once recognized, it became the question in what line the efforts to this end would be likely to be most profitable. A little thought showed that it was in investigating high electrical pressures, for these were needed in most instances. More than a passing thought was given to static electricity, with the experiments of Franklin as starting point. Various forms of generators of static electricity were experimented upon, and some new ones designed, to which I hope to revert some time, as they present some features of interest. The most valuable outcome of these experiments was a method of conversion which I have described, and which enables the operation of any kind of devices of low tension from such a high-pressure source with perfect ease and safety, no matter how high the tension. Soon, however, it was recognized that with the above object in view generators of steady pressure were entirely impractical, quite apart from their incidental limitations. It was exactly as if one attempted to drive piles into the ground by the application of continuous pressure. This would require cumbersome and powerful machinery, and would be very inconvenient. An incomparably better way of developing high pressure is by delivering violent blows as with a hammer. In such a case the motion of the hammer being suddenly arrested pressure is developed on the point of impact, which is all the greater the smaller the displacement caused, and if there were material absolutely rigid, incompressible and inelastic, an infinite pressure might thus be developed by a small blow.

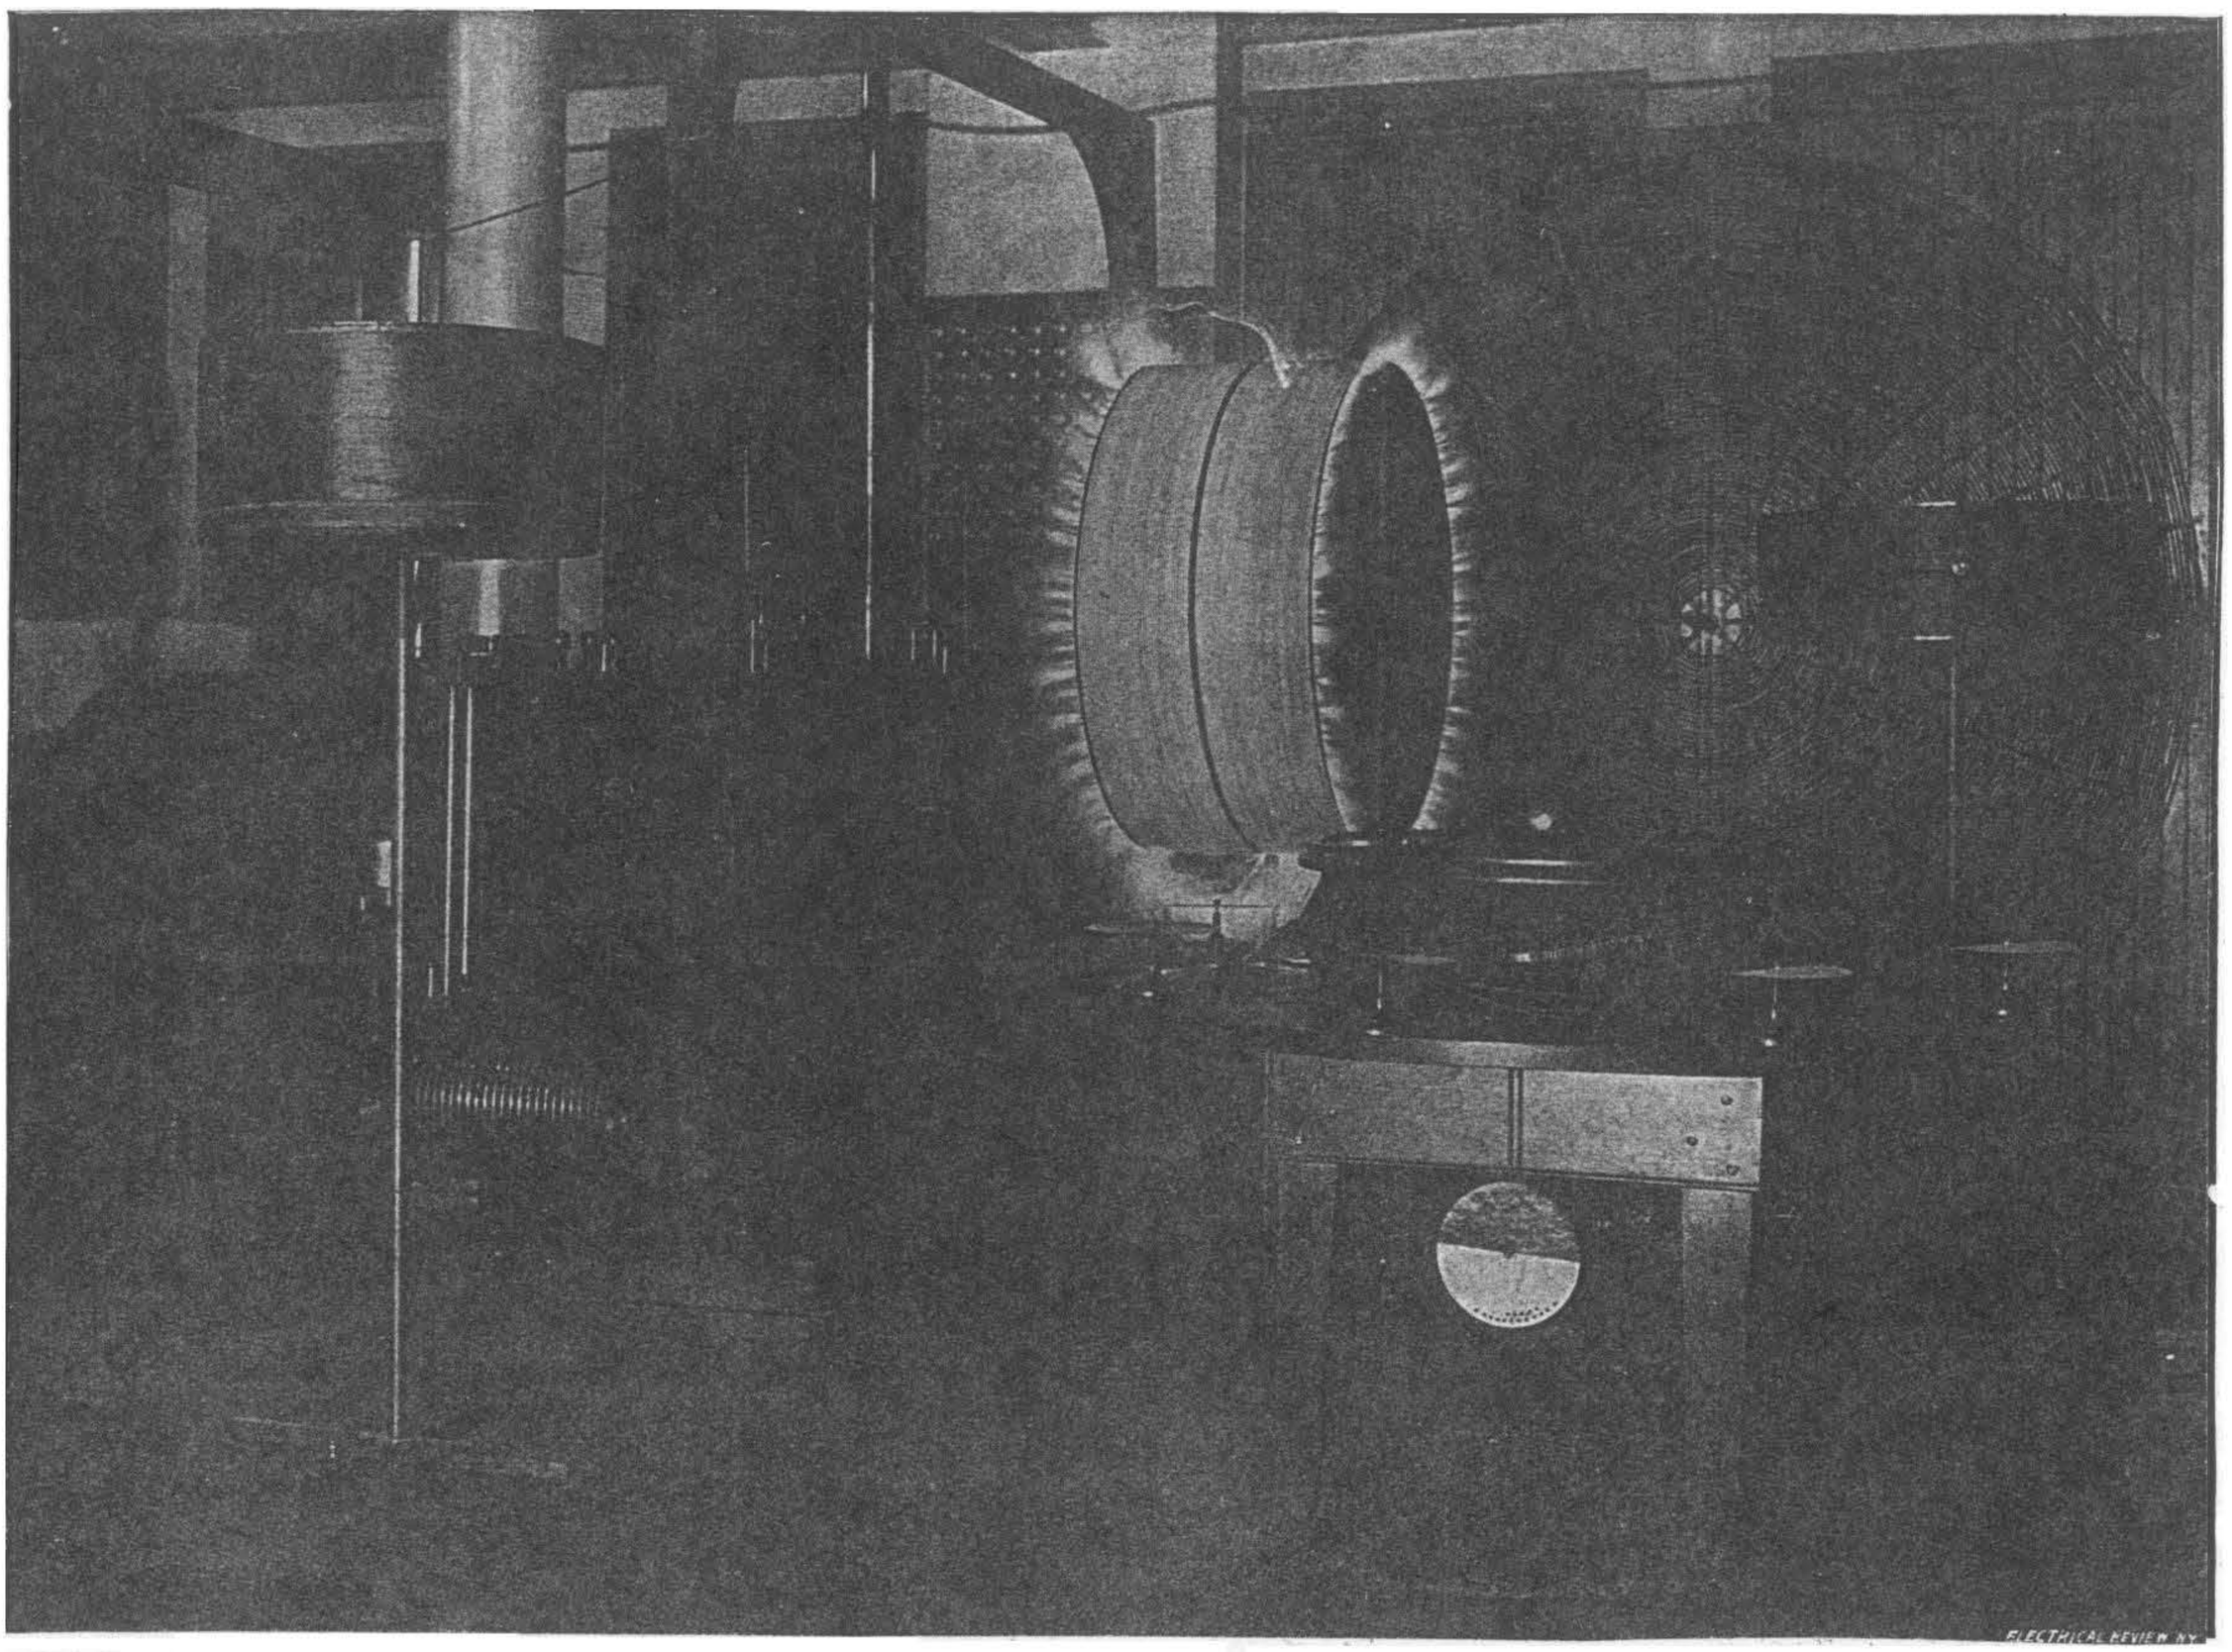

FIG. 3.—"SOME EXPERIMENTS IN TESLA'S LABORATORY WITH CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY"—PHOTOGRAPH SHOWING A PART OF THE LABORATORY, WITH A DISCONNECTED RESONATING COIL SUPPORTED ON AN INSULATING STAND, AND ILLUMINATED BY THE STREAMERS PRODUCED, OTHER COILS REMAINING UNAFFECTED—THE PRESSURE DEVELOPED IN THE RESONATING COIL IS OVER HALF A MILLION VOLTS.

Hence one is forcibly driven to the use of a transformer or induction coil as means for producing great electrical pressures. The first difficulty encountered was that of insulation, and it might be interesting and useful to show, chiefly to those who are less familiar with this special subject, how by gradual improvement, from the ordinary inductorium capable of furnishing currents of very moderate electro-motive force, an apparatus was finally evolved in which there is practically no limit as to the pressure obtainable.

Selecting first the closed core transformer, one easily recognizes that it is unsuitable for the attainment of the object in view for obvious reasons. Nevertheless, by adopting the plan illustrated in the first diagram of Fig. 2. I succeeded in obtaining nearly 200,000 volts, and I think that more than twice this tension is practicable by means of such an arrangement, which involves the use of independent and entirely insulated sources for supplying the primaries, as will be understood from an inspection of the diagram without further explanation. The evident limitations of the closed-core type in the way of insulation, rate of change and frequency of the current impulses, led to the adoption of an open-core type,

FIG. 8. — PHOTOGRAPH OF THE EXPERIMENTER STANDING IN THE MIDDLE OF THE LABORATORY AND LIGHTING A VACUUM BULB BY WAVES FROM A DISTANT OSCILLATOR—HIS BODY IS, IN THIS CASE, SUBJECTED TO GREAT ELECTRICAL PRESSURE.

as a matter of course, and the various diagrams of the figure referred to illustrate the modifications as they were gradually made in the manner of insulating and winding of the coils. In diagram 2 the old, primitive method of insulation is indicated. In diagram 3 the succeeding layers are insulated by material increasing in thickness gradually from one end to the other, being thickest on the place of greatest difference of potential. The thickness is easily calculated beforehand, and is such that all the insulation is as nearly as possible uniformly strained. As it was impracticable to pile up many layers in the manner illustrated in diagram 3, naturally the modification illustrated in diagram 4 was made, which led to a further improvement, indicated in diagram 5. It was recognized, however, that there was no advantage in winding many coils, and that all that was needed were two secondary coils joined in the middle, as illustrated in diagram 6, the secondaries being, of course, wound as shown in diagram 3. Next, in order to increase the output of the coil and gain other advantages, the relative customary position of the primary and secondary windings was reversed and the coil as shown in diagram 7 produced, the two secondary coils being joined on their outer, instead of on their inner ends, as before. This construction was considerably better than that illustrated in diagram 6, as the primary and secondary coils were placed in closer inductive relation. But when with this coil the tension had been pushed far enough, it was found that the iron core limited the spark length, and then two insulated cores, one in each coil, were resorted to, which were finally discarded, and so the coil shown in diagram 8 resulted, which I have described on several occasions and which, of all other constructions, permits the obtainment of the highest possible tension with a two-terminal coil in a given space.

But even in this perfected type it was not possible to go beyond a certain potential difference, and a further investigation led to a new type, which I have called a single terminal coil, and which is illustrated in diagram 9 and is now well known. In this coil the adjustment is so made that the secondary is nearly equal to a quarter of the wave length, the highest potential being, under these conditions, produced on the free terminal. Subsequently I extended such adjustment also to the coils in diagram 8, improving the same materially.

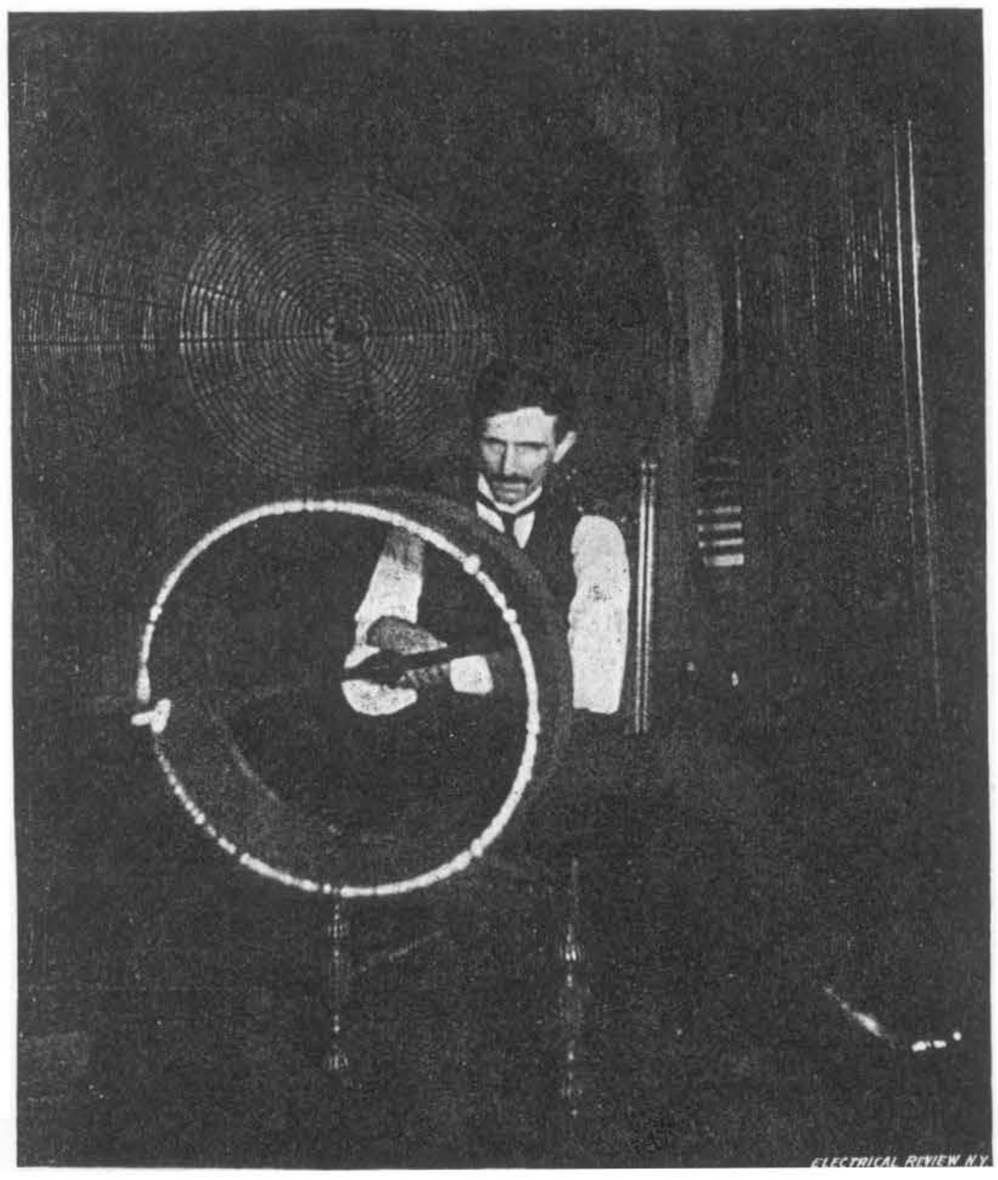

FIG. 7.—"SOME EXPERIMENTS IN TESLA'S LABORATORY WITH CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY"—EXPERIMENT SHOWING A COIL ENERGIZED BY THE WAVES OF A DISTANT OSCILLATOR AND ADJUSTED TO THE CAPACITY OF THE BODY OF THE OPERATOR, WHO PRESERVES HIMSELF FROM INJURY BY MAINTAINING A POSITION AT THE NODAL POINT, WHERE THE INTENSE VIBRATION IS LITTLE FELT—THE PRESSURE ON THE END OF THE COIL TOWARDS THE READER, WHICH IS ILLUMINATED BY THE POWERFUL STREAMERS, IS NEARLY HALF A MILLION VOLTS.

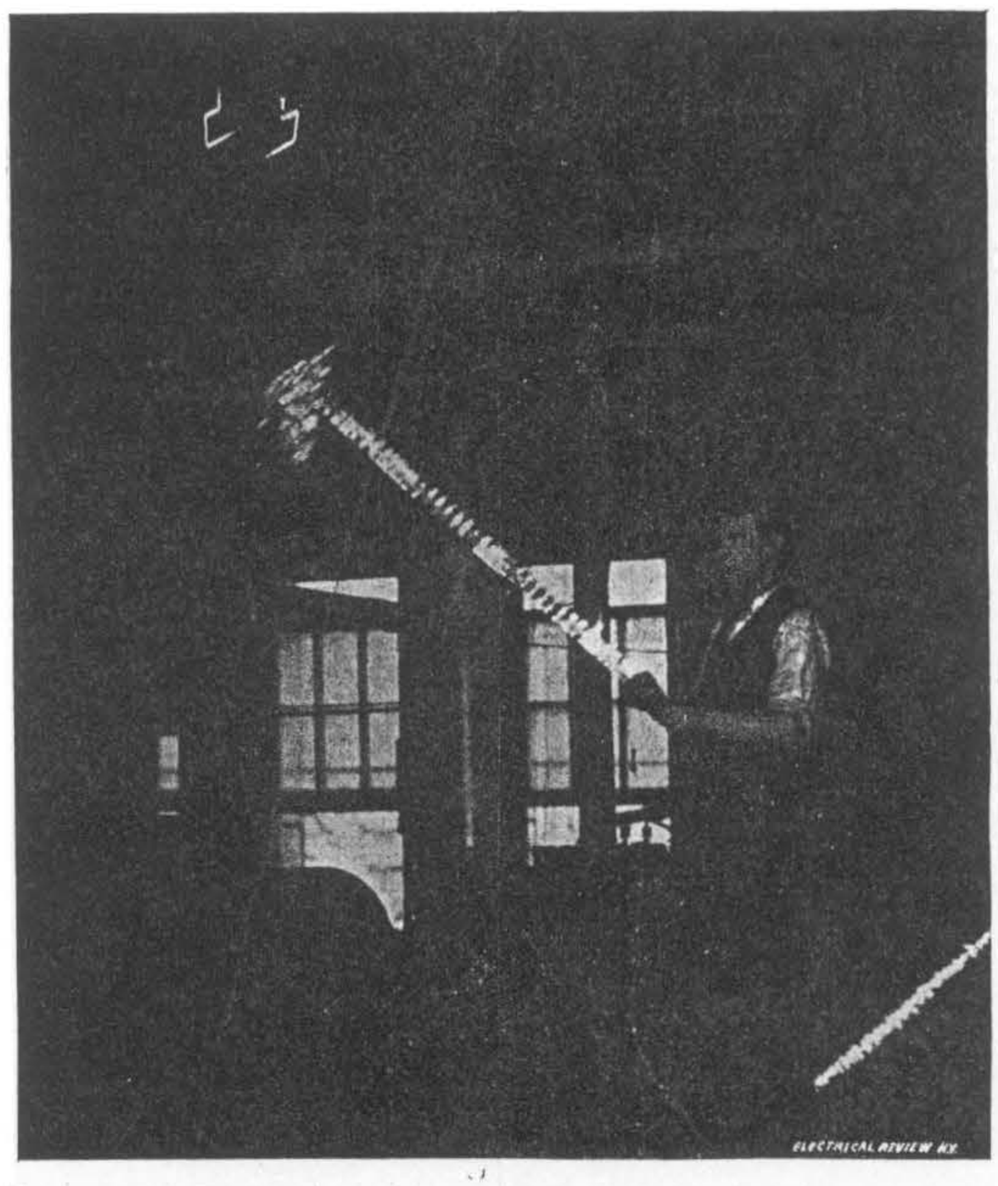

FIG. 10.—IN THIS EXPERIMENT THE OPERATOR'S BODY IS CHARGED TO A GREAT PRESSURE BY A DIRECT CONNECTION WITH AN OSCILLATOR—THE PHOTOGRAPH SHOWS A CONDUCTING BAR, CARRYING ON THE END A SHEET OF TIN OF DETERMINED SIZE, HELD IN HAND—THE OPERATOR IS ON THE TOP OF A STATIONARY ELECTRICAL WAVE AND THE BAR AND SHEET ARE BOTH ILLUMINATED BY THE VIOLENTLY AGITATED AIR SURROUNDING THEM—ONE OF THE VACUUM TUBES USED IN LIGHTING THE LABORATORY, THOUGH AT CONSIDERABLE DISTANCE ON THE CEILING, GLOWS BRIGHTLY, BEING AFFECTED BY THE VIBRATIONS TRANSMITTED TO IT FROM THE OPERATOR'S BODY.

During these efforts I fortunately discovered the important part which air played in the breaking down of the insulation, and by adopting proper methods for the exclusion of gaseous matter, I was able to increase the electro-motive force to more than 10 times the value without breaking down the secondary. I have described this method since, which I am using in the manufacture of coils and condensers, and without which it would be entirely impossible to reach any such results as I have obtained. The industrial world has profited by the recognition of the action of the air, for it has helped to extend power transmission to greater distances than heretofore practicable. It has also been useful in determining the limits of the electro-motive forces with ordinary apparatus used in power transmission, but I see that no attempt is yet made to overcome the streamers by a suitable construction of the cables, as I have indicated, and thus make higher electro-motive forces available.

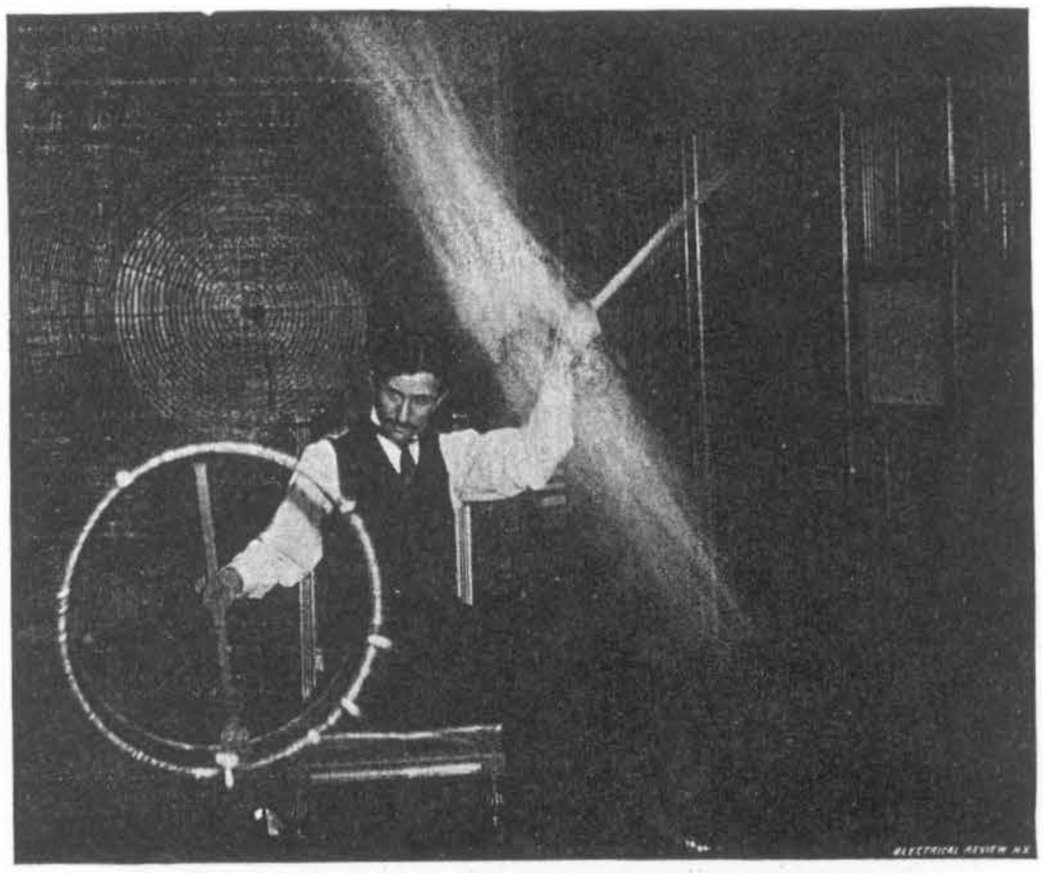

FIG. 9.—"SOME EXPERIMENTS IN TESLA'S LABORATORY WITH CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY"—THE OPERATOR'S BODY, IN THIS EXPERIMENT, IS CHARGED TO A HIGH POTENTIAL BY MEANS OF A COIL RESPONSIVE TO THE WAVES TRANSMITTED TO IT FROM A DISTANT OSCILLATOR, AND A LONG GLASS TUBE WAVED IN THE HAND IS LIGHTED TO GREAT BRILLIANCY BY THE ELECTRICAL CHARGES CONVEYED TO IT THROUGH THE BODY.

Further experimentation with the original single-terminal coil, before referred to, finally led step by step to the adoption of a coil of large dimensions, which, in two typical forms, is illustrated in diagrams 10 and 11. With such a coil I found that there was practically no limit to the tension obtainable, and it is by its means that I discovered the most important of all facts arrived at in the course of my investigation in these fields. One of these was that the atmospheric air, though ordinarily a perfect insulator, conducted freely the currents of immense electro-motive force producible by such coils and suitable accessories. So great is the conductivity of the air, that the discharge issuing from a single terminal behaves as if the atmosphere were rarefied. Another fact is that this conductivity increases very rapidly with the rarefaction of the atmosphere and augmentation of the electrical pressure, to such an extent that at barometric pressures which permit of no transit of ordinary currents, those generated by such a coil pass with great freedom through the air as through a copper wire. Following up these promising revelations I demonstrated conclusively by experiments that great amounts of electrical energy can be transmitted to any distance through upper air strata which are easily accessible, and since this truth has been recognized every fiber has been strained to realize such a transmission on a large scale. These two observations explain clearly the silent discharges noted frequently in dense air strata, but three or four miles above the earth's surface. One more equally important fact I may mention, which was simultaneously observed. The discharges of such a coil, when of an electro-motive force of a few millions of volts, excite powerful affinities in the atmospheric nitrogen, causing it to combine readily with the oxygen and other elements, particularly in the presence of aqueous vapor. So energetic are these actions and so strangely do such powerful discharges behave, that I have often experienced a fear that the atmosphere might be ignited, a terrible possibility, which Sir William Crookes, with his piercing intellect, has already considered. Who knows but such a calamity is possible? And who can tell with certitude that periodical cessations of organic life on the globe might not be caused by ignition of the air and destruction of its life-sustaining qualities, accidentally or as a consequence of some accumulative change? A lump of coal will lie for centuries unaffected in contact with oxygen, but the combustion once started, the process continues as long as there are elements to combine.

While improving the construction of the transformers, every effort was made to perfect the apparatus for generating the currents. The objective point from the outset was to obtain the greatest possible rate of variation. High-frequency alternators were first used, but their limitations were soon apparent. I then turned again to make and break devices, chiefly with the object of using them in connection with a novel form of transformer, which I have previously described, and which is now well known and understood. In its original form, as I first showed it, it is illustrated in diagram 12, which need not be dwelt upon, beyond saying that one of the characteristic features of such an instrument is the energizing of the primary of the induction coil by the rapidly succeeding discharges of a condenser. In a more recent type, specially adapted for ordinary supply circuits, which I have described and shown before several scientific societies, the transformer comprises, as indicated in diagram 13, three coils, there being, in addition to the primary and secondary coils, one which receives the currents from the supply circuit, and is designated the charging coil. Pref-

TESLA'S LABORATORY EXPERIMENTS.

(*Concluded from page 197.*)

erably the latter is not in inductive relation with the former. On a number of occasions I have described high-frequency apparatus embodying this beautiful method, which has already been of great value to science in my hands as well as in those of others. But a defect, to which I called attention early, still confronted me. It lay in the make and break devices which performed the function of charging and discharging the condenser. Many of such devices, based on a variety of principles, formed the subject of experiments carried on with the aim of doing away with this imperfection. To cite one of these, the current from the source of supply was passed through a minute column of conducting liquid maintained in a variety of ways, and in this simple manner rapidly succeeding impulses were obtained. Incidentally, some useful results were secured with these contrivances, as, for example, the generation of currents of differing phase and the production of rotating fields moving with constant velocity; but, interesting as these simple devices were, they naturally precluded the possibility of economical conversion. Their study, however, was useful as a means of recognizing the requirements of such make and break apparatus, and, finally, led to forms based on scientific and economical principles. A number of these were recently described in technical periodicals and, as stated on a former occasion, they fulfill their difficult duty surprisingly well and make it possible to obtain currents of very high frequency from ordinary supply circuits with great economy. These novel contrivances lend themselves well also to the uses of the ordinary induction coil, and I have employed them with equal success in a form of Planté's rheostatic machine and for many other useful purposes. Thus, after a continuous effort extending through a number of years, I have the supreme satisfaction of having carried this hard and important task to a satisfactory end.

The annexed photographs will serve to convey an idea of what can be done with these perfected implements. Referring to Fig. 1, illustrative of the high rate of change obtained in the current, a vacuum bulb of about 12 inches in diameter is held in front of a coil of four turns of specially constructed heavy cable, through which a condenser is discharging, and, although at a distance of several inches from the coil, the gas in the bulb is brought to intense incandescence, the light emitted being fully equal to 1,500 candles. Such a powerfully energized coil, when the frequency, as in this instance, is measured in millions per second, shows little repellent action, but when the frequency of the impulses is low, closed conductors, as washers of conducting material, are thrown off with a force of a magnitude which can be only explained on the assumption that the currents have maximum values of many hundred thousand amperes.

The remaining photographs will be understood from the titles, which are made explicit for this purpose. I hope to have in the near future an opportunity for describing more of such experiments, and dwelling in detail on the apparatus used. For the present I am compelled, for want of time, to merely state that the vibrations used in most of them were from 400,000 to 800,000 per second.

In conclusion I wish to apologize for the frequent appearance of my likeness in these photographs, which is distasteful to me, but was unavoidable. Most of the advances indicated, and a number of others, have resulted from the application of the beautiful principle upon which the operation of this apparatus is based. Scientific men have honored me by identifying it with my name, and I have earnestly endeavored to show myself worthier of this great distinction by devoting to it much of my energies. No desire for material advantages has animated me in all this work, though I hope, for the sake of the continuance of my labors, that these will soon follow, naturally, as a compensation for valuable services rendered to science and industry. To the scientific experts, who are familiar, in theory and experiment, with electrical vibrations, the results here shown will, I believe, speak in eloquent language. But those readers to whom they are naturally less intelligible will ask: What are they good for, and what do they or have they demonstrated? To them it may be said that they have shown and proved among many other things: That ordinary currents can be transformed with high economy into electrical vibrations of any pitch, which are needed in many novel arts; they have shown that electrical energy in great amounts can be efficiently and safely transmitted without the use of wires to any point of the globe, however distant; they have furnished proof that the movements and operation of bodies and machinery carried by the same can be controlled from a great distance without any tangible connection whatever and with absolute precision; they have proved the practicability of a system of signaling without wires, not with the imperfect appliances as before attempted, which can not be tuned and are rendered useless by the play of a small induction coil, but by means of apparatus producing powerful oscillations and circuits in exact synchronism, with which it is impossible to interfere; they have shown that atmospheric nitrogen can be readily combined and valuable products manufactured, merely by the application of cheap water power, and that light, diffusive like that of the sun, can be produced with an economy greater than obtainable in the usual ways and with lamps that never consume. N. TESLA.

New York, March 26.

TESLA'S LABORATORY EXPERIMENTS.

It is with great pleasure that we present to our readers, in this issue, the extraordinary results obtained by Mr. Tesla. The photographs taken in his laboratory are, we believe, the first of this kind that he has ever permitted to be published. The experiments on which he dwells, and which are evidently the result of years of patient labor, are, in our opinion, the most striking and promising that have been shown in years, and they can not fail to create a profound impression on scientific minds.

The New York Herald March 30, 1899

MORE WONDERS WORKED BY TESLA

Inventor Makes Marvellous Progress in Transmitting Electrical Energy Without the Use of Wires.

CONTROLS DEADLY CURRENT

Eight Million Volts of the Fluid Handled with Safety by Means of Oscillator.

SPARK AROUND THE GLOBE.

Nikola Tesla has further advanced his extraordinary experiments in transmitting electrical energy for commercial purposes without the use of wires. I called on him at the Waldorf-Astoria last night to learn the progress which he has made, and which amounts to this:—

The inventor can handle currents up to eight millions of volts, produced by his perfected oscillators; the current can be directed to any point at which arrangements have been made to receive it, and this can be accomplished without regard to distance or surrounding conditions.

These advances have been made since October, 1898, when the HERALD published an account of Mr. Tesla's discovery. Then the inventor thought environment would have a potent influence on the transmission. Now, he says, that handicap has been done away with.

MARVELS SHOWN IN PHOTOGRAPHS.

Referring to photographs, the current issue of the Electrical Review says:—

"In one illustration the inventor receives the electrical waves from a distance and develops a pressure of half a million volts in a coil which he holds in his hand, preserving himself against injury by maintaining a fixed position on the electrical wave, where the pressure developed is small. Another photograph shows an assistant receiving in his body the currents from an electrical oscillator, which pass through his body and make a metal bar glow in his hands, also lighting a vaccum tube on the ceiling."

"To the scientific experts who are familiar, in theory and experiment, with electrical vibration, the results here shown will, I believe, speak in eloquent language," said Mr. Tesla, in a communication to the Review, "but those readers to whom they are naturally less intelligible will ask:—'What are they good for, and what do they or have they demonstrated?'

"To them it may be said that they have shown and proved, among many other things, that ordinary currents can be transformed with high economy into electrical vibrations of any pitch, which are needed in many novel arts; they have shown that electrical energy in great amounts can be efficiently and safely transmitted without the use of wires to any point of the globe, however distant; they have furnished proof that the movements and operation of bodies and machinery carried by the same can be controlled from a great distance without any tangible connection whatever and with absolute precision.

SIGNALLING WITHOUT WIRES.

"They have also proved the practicability of a system of signalling without wires, not with the imperfect appliances as before attempted, which cannot be tuned and are rendered useless by the play of a small induction coil, but by means of apparatus producing powerful oscillations and circuits in exact synchronism, with which it is impossible to interfere. They have shown that atmospheric nitrogen can be readily combined and valuable products manufactured merely by the application of cheap water power, and that light, diffusive like that of the sun, can be produced with an economy greater than obtainable in the usual ways, and with lamps that never consume."

The Review, in its editorial comment, says:—

"The experiments on which Tesla dwells and which are evidently the result of years of patient labor, are, in our opinion, the most striking and promising that have been shown in years, and they cannot fail to create profound impression on scientific minds."

The New York Times March 30, 1899

TESLA'S ELECTRIC DISCOVERY.

The Electrical Review Pronounces His Experiments the Most Striking and Promising in Years.

The current issue of the Electrical Review contains the first elaborate description published of experiments carried on in Nikola Tesla's laboratory demonstrating his recently announced discoveries in the application of electricity to commercial purposes without the use of conducting wires. The experiments involve the handling of currents up to 8,000,000 volts produced by his perfected oscillators, with entire safety. Photographs of the experiments performed make it appear that the energy can be directed to any point desired, regardless of distance and environment.

In one illustration the inventor receives the electrical waves from a distance, and develops a pressure of half a million volts in a coil which he holds in his hand, preserving himself against injury by maintaining a fixed position on the electrical wave where the pressure developed is small. Another photograph shows an assistant receiving in his body the currents from an electrical oscillator, which pass through his body and make a metal bar glow in his hands, also lighting a vacuum tube on the ceiling.

In concluding his communication to The Electrical Review, Tesla says that it is proved, among many other things, that ordinary currents can be transformed with high economy into electrical vibrations of any pitch, which are needed in many novel arts; that electrical energy in great amounts can be efficiently and safely transmitted without the use of wires to any point of the globe, however distant; that the movements and operation of bodies and machinery carried by the same can be controlled from a great distance, without any tangible connection whatever and with absolute precision; the practicability of a system of signaling without wires; that atmospheric nitrogen can be readily combined and valuable products manufactured merely by the application of cheap water power, and that light, diffusive like that of the sun, can be produced with an economy greater than obtainable in the usual ways, and with lamps that never consume.

The Electrical Review in its editorial comment, says: "The experiments on which Tesla dwells, and which are evidently the result of years of patient labor, are, in our opinion, the most striking and promising that have been shown in years, and they cannot fail to create a profound impression on scientific minds.

Wireless Telegraphy for Yacht Races.

LONDON, March 30.—According to a dispatch to The Daily Chronicle from Dover Signor Marconi, whose brilliantly successful experiments with wireless telegraphy across the Strait of Dover have excited the liveliest interest, says he has received an offer to report the American Cup races for certain American newspapers.

HIGH PRESSURES AND HIGH FREQUENCIES.

There is no department of electrical study so fascinating as that dealing with high pressures and frequencies. While the first knowledge of electricity came through the study of high-pressure phenomena, interest in these waned and almost disappeared after the introduction of current electricity as a working force. The almost incredible development of knowledge in this department, the great industrial evolution it accomplished, the vast benefits arising from the completion of each step in advance, so accelerated the progress of the electrical arts that, to-day, application of the ordinary forms of electric current —direct, alternating, polyphase— may almost be said to be a finished subject. Its era of rapid progress is passed; it can only improve by the little betterments of detail suggested by experience.

But the really great field of electrical study remains, for the most part, unexplored. It is to electricity at high pressures and at high rates of vibration, or both, that we must look for new progress. So little is known of the beautiful phenomena of electrical action under such circumstances, so much can be imagined, that the least attempt at prophecy is dangerous.

The very few enthusiastic investigators who have left the beaten track to explore this fascinating region have already produced amazing results. In these pages, last week, was an account of the remarkable work of Mr. Tesla with currents of high potential and frequency. Such results as this patient and earnest experimentalist in the field of science has accomplished lie so far without the range of usual experience that no comparison of other results with them is possible. They stand apart, and it must be left to the future to judge of the value of their accomplishment.

Still; it is certain that every new fact of Nature discovered is finally beneficial, whether or not its utilitarian application is immediate. There seems vast promise in the new facts that Tesla presents; still vaster possibilities lie scattered through the new and interesting field to which he points. To this work must be given the large credit due to any effort to add to the world's store of knowledge. Its results may not always be immediate, but they can not fail to be extremely valuable — perhaps even revolutionary.

TESLA, America's Own and Only Non-Inventing Inventor, the Scientist of the Delmonico Café and Waldorf-Astoria Palm Garden, has been at it again. This time the news of young Marconi's success in telegraphing through space fired Tesla to feats hitherto undreamed of, and he filled columns in the *Herald*—which paper, I much fear me, inclines to help Tesla make a guy of himself—with profound droolings about volts and resistances and circuits and ampères and things and things. Tesla says he can do everything that Marconi has done. Of course he doesn't really do them, but that may be because he is afraid someone else may find out how they are done. He knows all about the theory and the practical machinery of Marconi's messages through miles of space, and could prove it too—if old Bill Jones was alive. Indeed, the actual results of the methods of the two inventors show only this slight difference: Marconi telegraphs through space and Tesla talks through space.

The New York Tribune April 9, 1899

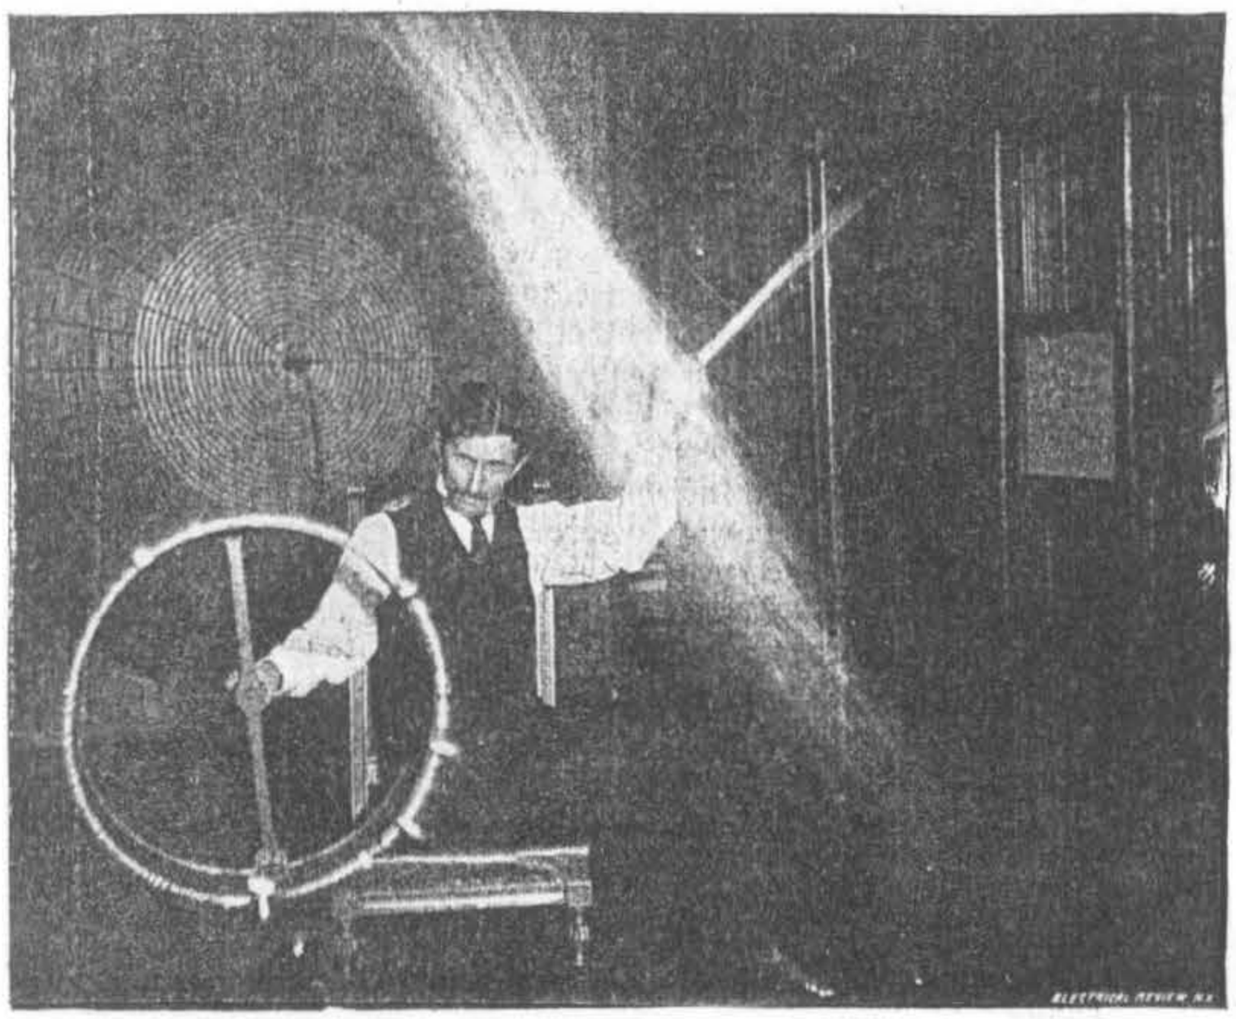
IF THE AIR SHOULD BURN UP

A STARTLING AND INCENDIARY POSSIBILITY, SUGGESTED BY MR. TESLA.

In a paper which Mr. Tesla recently contributed to the pages of "The Electrical Review" he mentioned a striking possibility. He was discussing his own apparatus for raising the potential, or pressure, of an electric current, when it is intended to transmit it through rarefied air from one point to another. He noted, in passing, the increased sensitiveness of atmospheric nitrogen when subjected to the influence of electricity at a high potential. That is to say, a gas which is ordinarily rather sluggish about combining with other chemical elements exhibits a more sociable disposition when a powerful current is passing through it.

This fact led Mr. Tesla to contemplate the contingency of a sudden union between the nitrogen of the air, along the route traversed by a high-pressure current, and the oxygen with which it is mechanically intermingled. Such an operation, it must be noted, would really amount to combustion. When any substance burns—wood, for instance—the inflammable part of it combines chemically with oxygen. A material that is burned is oxidized. Hence a chemical combination of the nitrogen with its principal fellow-constituent of the atmosphere would really be a burning process.

Now, if anything of this sort should ever happen, the combustion would be confined at first to the immediate vicinity of the path of the current. But many things, like a stick of wood or a piece of coal, when once ignited, continue to burn for a considerable period, the fire gradually extending from the place at which it began until the whole object is consumed. In like manner, Mr. Tesla suggested, if the earth's aerial envelope is ever set ablaze at all, it may keep on burning until it is altogether converted into something else. The best-known chemical combinations of oxygen and nitrogen are nitrous or nitric acids, and one or both of these would doubtless result from a conflagration of the kind here indicated. A complete removal of the atmosphere from the earth would put an end to winds, rain and weather in general. But inasmuch as it would also extinguish all animal life, the weather would not be missed.



The fact that lightning is attended with very high potentials, and has been at work in the atmosphere for thousands—probably millions—of years without having produced any result of this kind, so far as scientists know, is somewhat reassuring as to the future; but, after all, it does not absolutely guarantee humanity against the possibility to which Mr. Tesla calls attention. It is doubtful whether the voltages of an ordinary stroke of lightning are as great as those which Mr. Tesla secures with his new transformer. Setting the North River on fire is conceded to be an unattainable bit of incendiarism; but if Mr. Tesla is not cautious he may give the world an infinitely vaster display of fireworks.

Teslaic Experiments.—In the issue of the *Electrical Review* of New York for March 29 there is an illustrated article written by Mr. Nikola Tesla on some experiments he has carried out with currents of high potential and high frequency. The value of the description in question is much enhanced by the numerous illustrations in which Mr. Tesla himself appears very frequently as operating or supporting the various luminous bodies. The article is chiefly devoted to vacuum-tube lighting, and in the first illustration a bulb 12in. in diameter is shown held in the hand of its inventor, in which a light equal to 1,500 c.p. is said to be generated by the vacuum bulb being held in front of a coil of four turns through which a condenser is discharging. Mr. Tesla adds that "such a powerfully energised coil, when the frequency, as in this instance, is measured in millions per second, shows little repellent action, but when the frequency of the impulses is low, closed conductors, as washers of conducting material, are thrown off with a force of a magnitude which can be only explained on the assumption that the currents have maximum values of many hundred thousand amperes." In the second illustrations a series of diagrams showing the connections adopted by Mr. Tesla in the construction of his high-frequency coils are clearly illustrated, the object being to produce one pole of exceedingly high potential so that it will discharge freely into the atmosphere. This type of coil Mr. Tesla calls the single-terminal coil, and a number of illustrations are given in which it is seen to be discharging very freely. For instance, in Fig. 11 a photograph of the actual terminal is shown such as Mr. Tesla wishes to use for the transmission of electrical energy to great distances without the use of wires. In this case, with a pressure on the terminal of about 8,000,000 volts, the width of space illuminated by the discharge is some 18ft. A good deal of attention is also drawn to the way in which such apparatus can be handled without danger. The author also claims that the energy developed in the bulbs is comparatively small. But no figures are given to enable one to judge whether the high candle-power obtained in several cases is more economically produced than by, say, arc lighting. Another point taken up is the action of these discharges into the air, in which E.M.F. is measured in millions of volts. Mr. Tesla states that such discharges excited powerful affinities in the atmospheric nitrogen, causing it to combine readily with the oxygen and other elements present in the air. This is particularly the case when aqueous vapour is present. In fact, to quote the author verbatim, "so energetic are these actions and so strangely do such powerful discharges behave, that I have often experienced a fear that the atmosphere might be ignited, a terrible possibility which Sir William Crookes, with his piercing intellect, has already considered. Who knows but such a calamity is possible? And who can tell with certitude that periodical cessations of organic life on the globe might not be caused by ignition of the air and destruction of its life-sustaining qualities, accidentally or as a consequence of some accumulative change?" One pleasing feature in the reproduction of the photographs taken in Mr. Tesla's laboratory is that a description of the apparatus used is placed underneath each of these. The author in certain parts of the article refers to his labours in other directions, such as an invention of a means for the annihilation of the English fleet. One cannot help wishing, however, that he would devote his attention more to the development of vacuum-tube lighting until its commercial possibility is either proved or disproved.

SCIENCE AND INVENTION.

RECENT EXPERIMENTS BY TESLA.

NIKOLA TESLA contributes to *The Electrical Review* (March 29) an illustrated account of some of his latest experiments in the building of improved induction-coils for the development of great electrical pressure. Mr. Tesla says that it is

SOME EXPERIMENTS IN TESLA'S LABORATORY WITH CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY.

The operator's body, in this experiment, is charged to a high potential by means of a coil responsive to the waves transmitted to it from a distant oscillator, and a long glass tube waved in the hand is lighted to great brilliancy by the electrical charges conveyed to it through the body.

Courtesy of *The Electrical Review.*

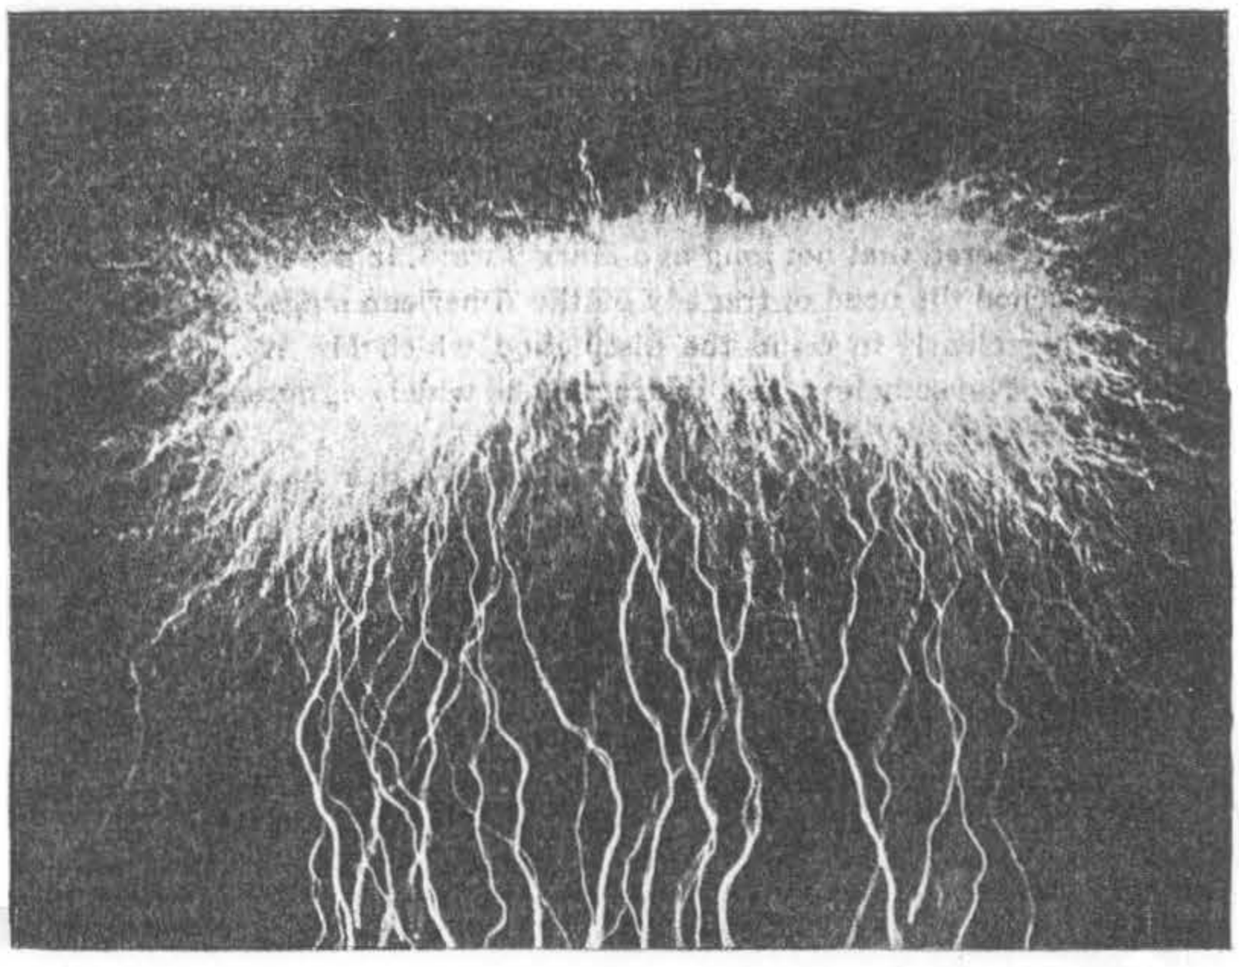
easier for him to invent than it is to perfect and to record his inventions. He puts it thus:

"Ideas come through a happy inspiration, apparently without much exertion; but it is the working out of the many harassing details and putting into a presentable form which consumes time and energy. It was impossible to abandon research in new directions, in which I have felt myself irresistibly drawn, and it was equally impossible to do full justice to the work partially completed, and I can only hope gradually to retrieve my losses by the only expedient available, which is to redouble the zeal."

The author pays his respects to the sensation-loving public, which at intervals attributes to his genius some new miracle, to the disgust of sober and slow-going, native-born scientists. "Some people," he says,

"have found a singular satisfaction in dwelling extensively in their columns on my proposed glass-house on Long Island, which was to cover acres of ground, and which was to be built for the purpose of catching the sun's rays; on my claims of the discoveries of Roentgen; on my invention enabling me to move and explode torpedo-boats by will power, and on my efforts to annihilate the entire British navy. It is to be hoped that the limits of patience of the readers have been finally reached."

The inventor next describes the process of thought that led him to devote special attention to the improvement of induction-coils. He says:



"The importance of the task of providing proper implements for research in these various fields once recognized, it became the question in what line the efforts to this end would be likely to be most profitable. A little thought showed that it was in investigating high electrical pressures, for these were needed in most instances. . . . . .

"Soon it was recognized that . . . generators of steady pressure were entirely impractical, quite apart from their incidental limitations. It was exactly as if one attempted to drive piles into the ground by the application of continuous pressure. This would require cumbersome and powerful machinery, and would be very inconvenient. An incomparably better way of developing high pressure is by delivering violent blows as with a hammer. In such a case the motion of the hammer being suddenly arrested pressure is developed on the point of impact, which is all the greater the smaller the displacement caused; and if there were material absolutely rigid, incompressible, and inelastic, an infinite pressure might thus be developed by a small blow. Hence one is forcibly driven to the use of a transformer or induction-coil as a means for producing great electrical pressures."

We can not follow the inventor in his detailed description of his work. The first difficulty he encountered was that of insulation, but by clever devices and by various alterations of position and arrangement in his primary and secondary coils, he finally attained remarkable results. His final and most radical improvement is thus described:

"During these efforts I fortunately discovered the important part which air played in the breaking down of the insulation, and by adopting proper methods for the exclusion of gaseous matter, I was able to increase the electromotive force to more than ten times the value without breaking down the secondary. I have described this method since, which I am using in the manufacture of coils and condensers, and without which it would be entirely impossible to reach any such results as I have obtained. The industrial world has profited by the recognition of the action of the air, for it has helped to extend power transmission to greater distances than heretofore practicable. . . . . .

"Further experimentation . . . finally led step by step to the adoption of a coil of large dimensions. . . . With such a coil I found that there was practically no limit to the tension obtain-

PHOTOGRAPH OF AN ACTIVE TERMINAL OF AN IMPROVED OSCILLATOR, USED IN TESLA'S EXPERIMENTS FOR TRANSMITTING ELECTRICAL ENERGY TO GREAT DISTANCES WITHOUT WIRES.

Width of illuminated space is 18 feet—the pressure on the terminal is about eight million volts.

Courtesy of *The Electrical Review.*

able, and it is by its means that I discovered the most important of all facts arrived at in the course of my investigation in these fields. One of these was that the atmospheric air, tho ordinarily a perfect insulator, conducted freely the currents of immense electromotive force producible by such coils and suitable accessories. So great is the conductivity of the air that the discharge issuing from a single terminal behaves as if the atmosphere were rarefied. Another fact is that this conductivity increases very rapidly with the rarefaction of the atmosphere and augmentation of the electrical pressure, to such an extent that at barometric pressures which permit of no transit of ordinary currents, those generated by such a coil pass with great freedom through the air as through a copper wire. Following up these promising revelations I demonstrated conclusively by experiments that great amounts of electrical energy can be transmitted to any distance through upper-air strata which are easily accessible, and since this truth has been recognized every fiber has been strained to realize such a transmission on a large scale. These two observations explain clearly the silent discharges noted frequently in dense-air strata, but three or four miles above the earth's surface. One more equally important fact I may mention, which was simultaneously observed. The discharges of such a coil, when of an electromotive force of a few millions of volts, excite powerful affinities in the atmospheric nitrogen, causing it to combine readily with the oxygen and other elements, particularly in the presence of aqueous vapor. So energetic are these actions and so strangely do such powerful discharges behave, that I have often experienced a fear that the atmosphere might be ignited, a terrible possibility, which Sir William Crookes, with his piercing intellect, has already considered. Who knows but such a calamity is possible? And who can tell with certitude that periodical cessations of organic life on the globe might not be caused by ignition of the air and destruction of its life-sustaining qualities, accidentally or as a consequence of some accumulative change? A lump of coal will lie for centuries unaffected in contact with oxygen, but the combustion once started, the process continues as long as there are elements to combine."

Tesla on the Wehnelt Interrupter.—Tesla lets himself out on the Wehnelt interrupter in the *Electrical Review*, (New York), March 15th. He invented this device two or three years ago. This belated publication in our contemporary would not, according to the generally accepted code, secure to Tesla the credit of being the inventor, but Tesla evidently does not regret this, since he considers there is no merit in the invention. It wastes, in his opinion, 90 per cent. of the energy, and is objectionable for other reasons which he does not specify. He mentions another interrupter based on a different principle which is incomparably more efficient, and also simpler on the whole. It comprises a fine stream of conducting fluid which is made to issue, with any desired speed, from an orifice connected with one pole of a generator, through the primary of the induction coil, against the other terminal of the generator placed at a small distance. This device gives discharges of a remarkable suddenness, and the frequency may be brought within reasonable limits, almost to anything desired. He has used this device for a long time in connection with ordinary coils and in a form of coil of his own with results greatly superior in every respect to those obtainable with the form of device discussed.

The New York Tribune April 23, 1899

ACTION AT A DISTANCE.

MODERN WONDERS WROUGHT BY ELECTRICITY.

A SUGGESTION TO TESLA—HIS SYSTEM OF CONTROLLING VESSELS—POWER TRANSMISSION.

The suggestion was made not long ago by Szczepanik, the inventor of the telectroscope, that Mr. Tesla might find a flying machine a good subject for experiment in testing his apparatus for controlling the movements of a vehicle at a distance. The idea is not a bad one; but it involves difficulties which the young Pole probably has not considered.

Mr. Tesla had in view, when he worked on his scheme last summer, the control of marine vessels capable of carrying a storage battery and propelled and steered electrically. But a storage battery is heavy, and, although it has been tried on a small scale in aerial navigation, the tendency of late years has been toward the construction and use of extremely light steam or gasolene engines instead of electric motors. In this manner it seems to be practicable to reduce the weight of the machinery in proportion to the power developed. In so dense a medium as sea water a craft laden with a considerable number of accumulator cells would easily preserve its buoyancy, but the case is different with an airship. Again, it is the ambition of the aerial navigator to traverse scores, even hundreds of miles, after once launching out upon a voyage, whereas Mr. Tesla, while studying how to project against an enemy's warship a more formidable quantity of high explosives than has hitherto been used, apparently contemplated shorter trips.

In view of the lively interest now taken by the enlightened public in electrical action at a distance without wires a fresh consideration of Mr. Tesla's plan is not out of place. In his patent, applied for last July, and taken out in November, he says:

> The invention which I have described may prove useful in many ways. Vessels or vehicles of any suitable kind may be used, as life, dispatch or pilot boats or the like, or for carrying letters, packages, provisions, instruments, objects or materials of any description, for establishing communication with inaccessible regions and exploring conditions existing in the same, for killing or capturing whales or other animals of the sea, and for many other scientific engineering or commercial purposes. But the greatest value of my invention will result from its effect upon warfare and armaments; for, by reason of its certain and unlimited destructiveness, it will tend to bring about and maintain permanent peace among nations.

Mr. Tesla provides for a base of operations on the shore or on a big ship at sea. Here the man who controls the movements of the crewless torpedo-boat has before him a rotating device or switch, one complete turn of which admits four momentary impulses to a vertical wire and sends them off into the earth or other conducting medium. The wire leads down into the earth and upward along a pole, terminating overhead in a flat metal plate. Several forms of apparatus for generating the electric waves are mentioned as available for this service. They resemble in general the appliances which Mr. Tesla has proposed to use for wireless telegraphy.

The small boat is equipped with an uplifted metal plate, a wire running down from it into the vessel, a sensitive device through which any impulse excited in this "receiving circuit" must flow, and, finally, a wire leading to the keel of the boat and thus to the sea. As has been mentioned already, the boat carries a storage battery, and there are several wire circuits, each leading to a different set of instruments. These wires behave much like pipes on a steamship which conduct steam along various routes to perform different kinds of work. In each auxiliary circuit, acting like a valve to admit or shut off current, is the familiar "relay" of the telegrapher. This mechanism is so constructed that an exceedingly faint current, passing through one part of it, automatically opens up the way for the flow of another current through another channel.

But the master instrument is the sensitive device in the receiving circut. This is so arranged that it already has a weak current trying to flow through it, and needing only the least imaginable additional stimulus to promote success. The needed impulse is derived from the vibrations emitted from the distant land station, and communicated through the ether, sea or earth. The sensitive device performs somewhat the same function as the "coherer" of a Marconi telegraphic system, but is an original affair in design. Mr. Tesla regards it as much more trustworthy and efficient.

It is not necessary to describe in detail the apparatus inside the boat. It suffices to say that it has been tried in a model and works to perfection. The distant operator, by his manner of moving the switch, can start the boat ahead, stop it, and steer it to the right or the left. Automobile torpedoes carry a charge of one hundred or two hundred pounds of guncotton. A boat like this of Mr. Tesla might bear tons of explosive and work the instantaneous ruin of the stoutest war vessel ever conceived. No wonder that he regards himself as the ally of the Czar of Russia in putting an end to war!

The plan of producing action at a distance should not be confounded with that other startling project which Mr. Tesla broached last summer—the transmission of power through the upper air. In the work just described, only a very small quantity of energy is employed, and it unlocks another store of energy already existing at the distant point. Moreover, the vibrations are transmitted, not by the air, but by the land, sea or what the scientist, not the poet, means when he uses the word "ether." But Mr. Tesla's new power-transmission scheme contemplates such work as is now being done between Niagara and Buffalo, where several thousand horse-power in the form of electricity are sent over costly copper rods, mounted on a pole line and carefully insulated.

Not only is it proposed to convey enormous quantities of energy from one place to another over distances of hundreds of miles, but to dispense altogether with the metallic conductor and use the air instead. At ordinary densities, especially when dry, the air is an insulator, and not a conductor. But when sufficiently rarefied it will conduct admirably; and as the atmosphere grows more rare as the distance above the earth increases, one needs only to get up to a certain elevation to find the right degree of rarefaction.

The current which Mr. Tesla would use for this purpose would possess a very high potential or voltage, and this would be secured by a newly invented apparatus of his, a peculiar type of "transformer." Every schoolboy knows nowadays that when a current is transformed upward, the voltage increases, but the quantity, as expressed in amperes, is reduced. The total amount of energy is unchanged. A current of 300 amperes, sent at 25,000 volts, is equivalent to 7,500,000 watts or 10,000 horse-power. But if this current were transformed into one of a single ampere and 7,500,000 volts, it would still be equal to 10,000 horse-power.

Now, Mr. Tesla has already experimented with a voltage of several millions, and he believes that he could transform up to 100,000,000 volts. If, at such a potential, he had one whole ampere, he would be handling 133,333 horse-power! He conceives it possible to transmit a current like this for hundreds, not to say thousands, of miles, with the air as a conductor in the same sense that copper wire is.

At the present time, however, he is not ready to explain how he would support in the upper air the terminal apparatus of his sending and receiving station, nor to talk about plans for making a commercial application of this remarkable idea

NOTES ON LIGHT.

BY WILLIAM ROLLINS.

NOTE LIX—INTERMOLECULAR JOURNEYS.

I wish to state concisely what some who have read my previous notes have failed to understand; namely, that material particles can be made by electricity to pass between the molecules of cold, dense, homogeneous metals. This is true of even the densest metals I have been able to obtain for experiment. Mr. Tesla, who always sees everything in the direction he is looking, stated, I find in this journal three years ago, that particles of gas from the interior of a vacuum tube passed outward through the glass. These outward journeys left the tube in too exhausted a condition to do its work. Of return journeys through glass I shall speak later. I mention them now, hoping others will also give us practical solutions of the problem.

NOTE LX—SYMMETRY IN TUBES.

In designing the aim should be to combine efficiency with beauty. As before mentioned, a regulator on the side of a vacuum tube is not pleasing. I have, therefore, aimed to find better positions and have shown some of my results as applied to cooled terminal tubes. In Fig. 56 the same plan is applied to a tube with an uncooled target. The regulator is on one end of the tube serving also as a support for the anode stem and as a place to attach a wire from the generator. I have selected one of my rotary target tubes for the illustration, because these are in use in a large hospital where there is an apparatus that soon perforates a stationary uncooled target of the usual kind. It is now three years since I made a tube with a cooled target, which would bear 10 times the power of the generators in use. I hoped then to soon see such a rapid development that such tubes would be necessary, but, even at the present time, there is no commercial apparatus where the power is sufficient to make them essential. One can form no clear idea of the possibilities of this invaluable method of medical diagnosis from the results obtained with the best commercial apparatus. With the best generators available, no better results can be obtained in photography than the remarkable ones shown by Professor Goodspeed three years ago. We must turn to the experimental results of Tesla and Trowbridge to see what may be done. Take, for example, the fact that the latter has made a photograph of the bones of the hand in a millionth of a second. Why, it would tax the best commercial generator to the utmost to do this in less than 2,000,000 times as long. What a vista this opens. If we concentrate all the power of an ordinary generator on an oval spot on the target two millimeters long, a thin bit of platinum will stand the full force of the Crookes's stream without melting. This gives some idea of how feeble such an apparatus is. Speaking of the Crookes's stream reminds me that this was discovered by Varley, who published his work in 1871. He not only observed the cathode stream, but also its effect on a pivoted mica vane. This is another illustration of what I mentioned in Note LVII. As I learn more about vacuum tube research I am constantly finding similar cases, and, even with my present limited knowledge, could make quite a list of them. But to return to my subject. Is it not singular that three years after Roentgen's discovery of the transparency of the human body to some of Lenard's rays that this most important method of diagnosis should not have come into general use? Not one physician in a hundred employs it regularly, and yet with some diseases it enables us to make the earliest diagnosis. To show how important this is, take consumption, which is responsible for one-seventh of the deaths from disease. If every one would be regularly examined, a matter taking only a short time, most of the cases could be saved, for Williams has proved that the signs can be detected so early that treatment is followed by prompt recovery, many cases not even requiring a change of climate. This latter is of the utmost importance as consumption is a disease of the poor, who can not often give up their work and go away. The fluoroscope in Dr. Williams's hands is constantly showing evidences of old tubercle scars in patients who never suspected they had been attacked by the disease. This is a point of great interest, for if in so many cases nature has unaided effected a cure, we may expect, with a little help from medicine, that almost every case can be saved. These details may seem out of place in a non-medical journal, but they are introduced for a purpose, as I am convinced that outside pressure is needed to hasten the adoption of the most important method of diagnosis discovered in my lifetime. Although my own work in medicine is in a limited field, I am in a position to see the prime importance of the method and to be distressed at its slow adoption. I know that at present efficient apparatus must be built at home and that it is large and expensive, but if Mr. Tesla could be induced to work on the problem it would be quickly solved, the apparatus being made efficient, compact, powerful and not expensive. As stated in previous notes it is only a matter of harmonics—a little generator if we knew how to tune it could accomplish great results.

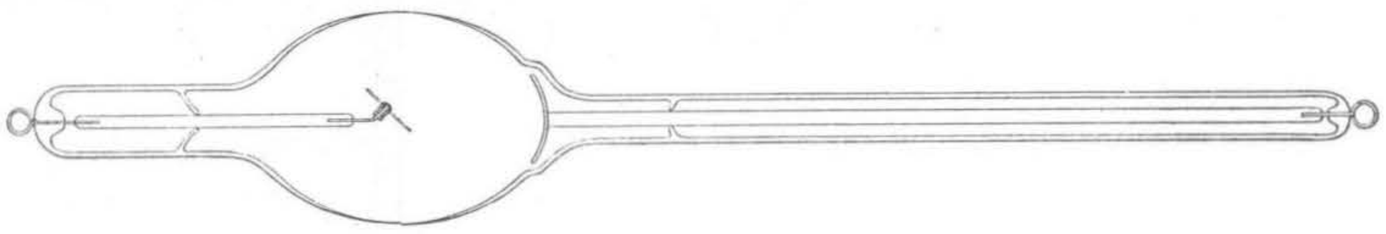


FIG. 56.—"NOTES ON LIGHT"—ROTARY TARGET TUBE WITH INTERMOLECULAR VACUUM REGULATOR AND TERMINALS WITH BARE STEMS.

NOTE LXI—ON GLASS WRAPPINGS.

Wrappings may have been appropriate for anything so old and dead as a mummy, but for vacuum tubes which are young and should be vigorous they are out of place. They are fetiches we have worshipped long enough. With any considerable force they get knocked from their pedestals, falling down as discolored fragments in the tube. As the glass wrapping about the anode stem was the first to go I tried the effect of shortening the stem, and finding this was an improvement, I also reduced the length of the wrapping, finally removing it entirely as in the tube here shown December 1, 1897. I next shortened that about the cathode stem and should have early abandoned it if two great experimenters, Lenard and Tesla, had not definitely stated that it was of value. I have now for some time discarded any covering for either terminal, not only without injury to the tube but to its distinct advantage. A tube of this kind is shown in Fig. 56. The method of supporting the bare stems is excellent and when these are of large diameter, three-sixteenths of an inch, the tube will bear any reasonable amount of jar in use or transportation. There is also another point about this tube which is of practical value—the large size of the wire loop forming the connection with the leading wire. These are usually small and delicate. They break easily and are difficult to find in a darkened room. It is irritating to hunt for the place to connect a wire, or to need to use care in its attachment. In some commercial tubes the danger of breaking the little wires is overcome by attaching brass caps on the ends, but these are objectionable as they prevent heating the tube, a process which should always be gone through with before exciting, to diminish the danger of puncture from the powerful current needed to overcome the high vacuums which are required for some work. Even with lower vacuums this preliminary heating is desirable, because with our present knowledge we can not make a tube which will give the same wave-length to the light when the tube is cold as when it has been run and become hot. A tube such as here shown is a small though distinct advance upon the usual commercial types.

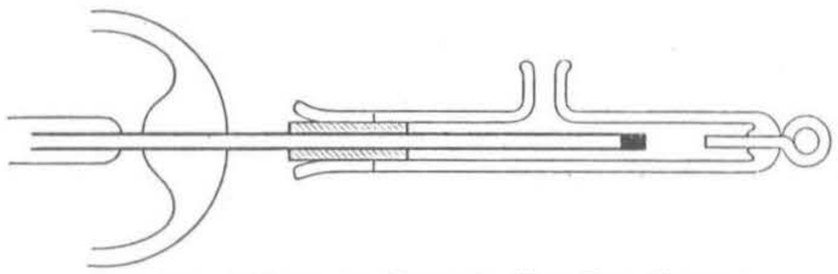

FIG. 57.—"NOTES ON LIGHT"—THE BON FEEDER.

NOTE LXII—THE BON FEEDER.

A friend having shown me a nursing tube of his invention, that had saved the life of a grandchild, I wanted to see if I also could not devise something new in this field. Having no grandchildren whose lives needed saving, it seemed best to construct it for a vacuum tube, which at that time was in a very exhausted condition. Fig. 57 shows the result. It is a bit of glass tubing partly filled with acidulated water held in by the rubber cork, which serves also as the support. To charge the regulator tube with hydrogen, connect the current in such a way that the gas will be liberated at the surface of the regulator tube, which should be of some metal that rapidly absorbs the gas. The device has amused me and may be of use to some one.

TESLA SAYS:

"Wireless telegraphy is a system of flashing signals by means of a light that is invisible, similar to the X-rays. Circles of this unseen, mysterious ligh instantly to any distance, even to Mars and Jupiter. If receiving terminals could be erected there the message could be intelligently and faithfully transmitted.

"To flash 2,000 or 3,000 words per minute to any part of the earth by the highly sensitized terminals I have perfected will be a common thing. It is nothing. inevitable. Distance no longer intimidates the electrician. I have demonstrated this week that messages may be sent with equal facility through the earth as by induc through the air. Neither distance nor the density of intervening objects will affect the speed or accuracy of the transmission of messages.

"THE PEOPLE OF NEW YORK CAN HAVE THEIR PRIVATE WIRELESS COMMUNICATION WITH FRIENDS AND ACQUAN ANCES IN VARIOUS PARTS OF THE GLOBE. IT WILL BE NO GREATER WONDER TO HAVE A CABLE TOWER ON YOUR RO THAN IT IS NOW TO HAVE A TELEPHONE IN YOUR HOUSE."---Nicola Tesla, the Distinguished Electrician, to the Journal.

Tesla's Wireless Telegraph Oscillator, Which He Proposes to Install on Balloons at New York and London and Telegraph Across the Ocean Without Cables
(From Photograph Taken for the Electrical Rewiew.)

THERE were two great developments in wireless telegraphy last week.

On Tuesday Marconi, the young Italian inventor, whose exploits in telegraphing so successfully between England and France across the English Channel had excited world-wide interest, admitted that the limit of his system had been reached.

Experiments made on the French dispatch boat Ibis that day had shown that the distances that could be covered by his system were limited to the height of poles that could be set up as terminals.

This would seem to show that Marconi's system is available only for short distances in signalling between ships and shore.

Before the cable had brought this discouraging news of an invention that so much has been expected from in the way of talking across oceans and continents without wires, Nikola Tesla perfected a discovery that he claims overcomes all the defects of the Marconi system.

By his new device he says he can start electrical waves that will travel across the ocean and completely around the world and bear messages with the swiftness of light.

To do this he will use instruments so similar to the ordinary telegraphic senders and receivers that the average person could not tell the difference between them.

The way he will make or start the electric waves to do this will be by means of his powerful oscillator, which the Journal has described several times in the past.

This is a great, round instrument, into which an ordinary current of electricity is turned from any dynamo. The oscillator instantly transforms it by a series of coils into an electro-motive force, vibrating at the rate of two to four million times a second. This starts electric waves through the air and earth, which vibrate almost as fast as the waves that produce light, and travel with the same speed.

But they are more like X rays than ordinary light, for they pass through dense things, like earth, stone and water, as easily as through the air and ether of space.

Mr. Nicola Tesla, who next to Thomas Edison is the foremost electrician in America, made this discovery six years ago. He has been at work perfecting it ever since. To make this of use in wireless telegraphy, one thing was needed. Last Tuesday Mr. Tesla exclaimed triumphantly that he had supplied the last link necessary for this purpose.

Nothing, Mr. Tesla says, can now obstruct or divert messages sent by this marvellous device. Words in incredible rapidity will be flashed across the broadest oceans and the widest continents. In fact, there is, according to the statements of the celebrated electrician, nothing to prevent the transmission of messages directly through the earth.

The construction of the wireless system is so simple and will be so inexpensive, that commercial firms and the great newspapers will have their own exclusive cable service.

"The people of New York," says Mr. Tesla, "can have their private wireless communication with friends and acquaintances in various parts of the globe.

"It will be no greater wonder to have a cable tower on your roof than it is now to have a telephone in your house.

"You will be able to send a 2,000-word dispatch from New York to London, Paris, Vienna, Constantinople, Bombay, Singapore, Tokio or Manila in less time than it takes now to ring up 'central.'

From a tower in Manila to a tower in New York City a message by wireless telegraphy, could be sent at no expense at all, in comparison with present cable rates, and without the danger of a moment's delay."

At his laboratory in East Houston street, surrounded by wires and motors and generators, Nikola Tesla was found yesterday by a representative of the Sunday Journal. The inventor was deep in the evolution of his great project.

"In 1893," said the inventor, "I predicted that messages would be sent throughout the world without wires. In an address delivered before the Franklin Institute, Philadelphia, in February of that year, I said a few words on this subject which even then constantly filled my thoughts. It was not a new idea—this wireless communication by signals. These demonstrations to-day in Europe by Marconi and others, and these triumphs in my laboratory had their crude genesis in the signal systems in vogue as early as the middle ages.

"Wireless telegraphy, to speak in unscientific terms, is a system of flashing signals, but by means of a light that is invisible, similar to the X rays. Circles of this unseen, mysterious light may be sped instantly to any distance—even to Mars and Jupiter, and if receiving terminals could be erected there, the message could be intelligently and faithfully transmitted.

"To flash 2,000 or 3,000 words per minute to any part of the earth by the highly sensitized terminals I have perfected will be a common thing. It is nothing. It is inevitable. Distance no longer intimidates the electrician. I have demonstrated, this week, that messages may be sent with equal facility through the earth as by induction through the air. The delicate and sensitive receiving device registers accurately every vibration of the transmitter. Neither distance or the density of intervening objects will affect the speed or accuracy of the transmission of messages.

"Accuracy and the avoidance of delay is secured by adjusting the receiving and transmitting contrivance to a common electric multiple. Then only the receiver prearranged and pre-adjusted, will record the message intended for it.

"By an understanding between operators in distant parts of the planet, code cipher messages will be sent with accuracy and with far greater speed than at present.

"Understand that I am not using scientific language. People generally misunderstand the system of wireless telegraphy, and I use ordinary expressions to make my meaning clear."

In more technical terms Mr. Tesla explained his rapid transmission of words by wireless telegraphy, and told how it could be put in operation between New York and London.

Two terminal stations should be established—one at New York and one at London. These may be captive balloons held by wi cables sent up to a height of 5,000 feet. This is necessary reach the upper strata of rarified air through which electr waves travel most easily. These balloon cables may be anch to steel towers. Just below each balloon should hang a dis large surface. The oscillators should be placed at the top o towers.

When the electrical movement is set up in the oscillator the towers, the current will rush upward to the terminal d under the balloons, where it will flash out starting vibrati that travel across the Atlantic Ocean. Currents will also downward from the towers into the earth by ground wires start similar vibrators to those in the upper air.

These electrical disturbances or vibrators, according to the tems being perfected by European electricians, diminish with distance, and the distance at which the effect will be percept will depend on the quantity of electricity set in motion.

"Not so with my system," says Mr. Tesla. "At least, not preciably so. One horse-power will operate a current betw New York and London. In 1890 a French scientist combine metallic dust that would register electric waves. This is by all the other experimenters in wireless telegraphy. My covery is infinitely more sensitive and receptive. That is secret I am not quite ready to exploit, as I shall first patent it.

"In 1893, as I have already said, I declared it was certain practicable to impress an electric vibration, at least of a certa low period, upon the earth, by means of proper machinery. At wh distance such a vibration might be made perceptible I then co only conjecture, but I said then that I believed it could not quire a great amount of energy to produce a disturbance p ceptible at a great distance, or even all over the surface of globe.

"We have progressed much since then, and these prophecie considered six years ago to be vain dreams are now becomin realities.

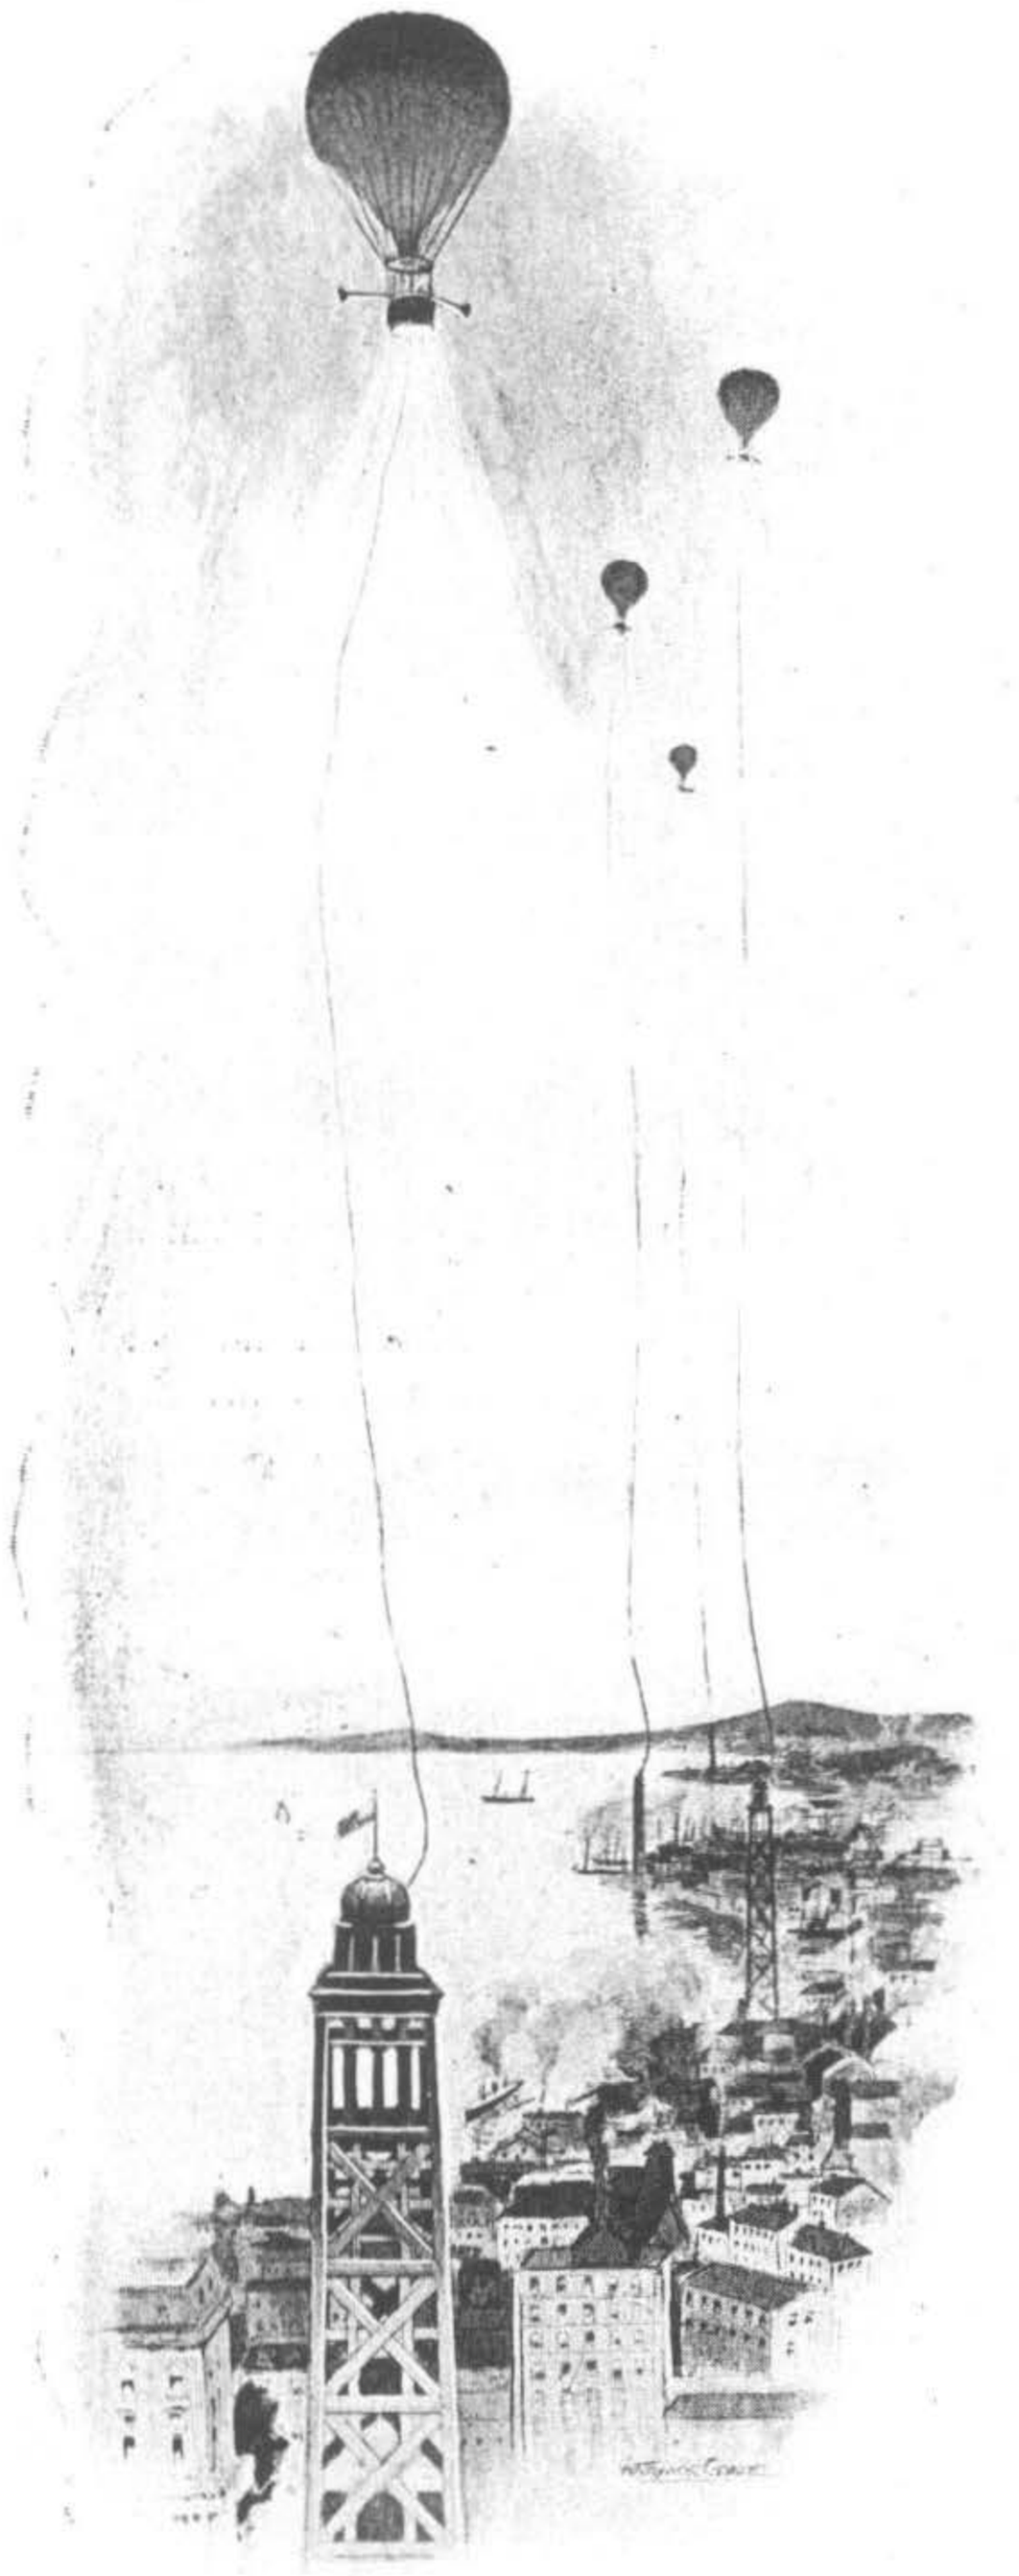
Mr. Tesla then said that the basic principle of wireless telegraphy given out by himself six years ago without being patented now makes it a free field for inventors and capitalists to enter.

"What effect will the general establishing of wireless tele graph stations throughout the world have?" Mr. Tesla was asked.

"The effect will be as pronounced, if not more so, than that produced by the introduction of ordinary telegraphy. We see now that time and space have been annihilated on this globe, but they have not been. They have been somewhat overcome. The complexity of transmission, the scarcity of wires in times of great happenings, congests the system. The tolls are excessive, absolutely prohibitive to millions of people. Under the system I have perfected companies will be able to send a message from New York to San Francisco, or London, or even far points like Zanzibar and Cape Town, for little more than we now pay for letter postage."

The introduction of wireless telegraphy on the scale contemplated by Mr. Tesla will be a great boon to the struggling country paper, but it will rob the big metropolitan papers of the glory of their fabulous cable bills. When it requires only the salary of two telegraph operators to secure news from central Siberia or northern China or from the remotest frontiers of all the earth, and when these far-sent messages flash into the office at the rate of 2,000 or 3,000 words per minute, the day of displaying achievements by cable shall have passed.

One operator in a tower above the Journal office could, in a few minutes, call up the principal cities of the world and learn of the day's doings of the race. To get news from Europe would be less of an undertaking than it is now to get a story by telephone from Bensonhurst.



Mr. Tesla thinks that many newspapers will enlarge their business under this system by furnishing news tickers to be placed in the towers of private houses. A family could thus read the Journal's telegraphic news and cables in brief as fast as they ticked into the telegraph editor's room. What a convenience at elections and times of wars in different parts of the world!

Already the common telegraph has done much to avert wars, making it possible for men to live in London, Paris, Berlin or New York and operate in every commercial capital. It has made many kinds of business international that were formerly confined to a single nation or city.

"Every city, every empire, will be nothing more than a suburb of the city in which you live," said its inventor.

Mr. Tesla says he is now ready to put his wireless telegraph system into operation between New York and London as soon as the practical details of the undertaking can be arranged.

Pearson's Magazine May 1899

Tesla's proposed arrangement of balloon stations for transmitting electricity without wires.

THE NEW WIZARD OF THE WEST.

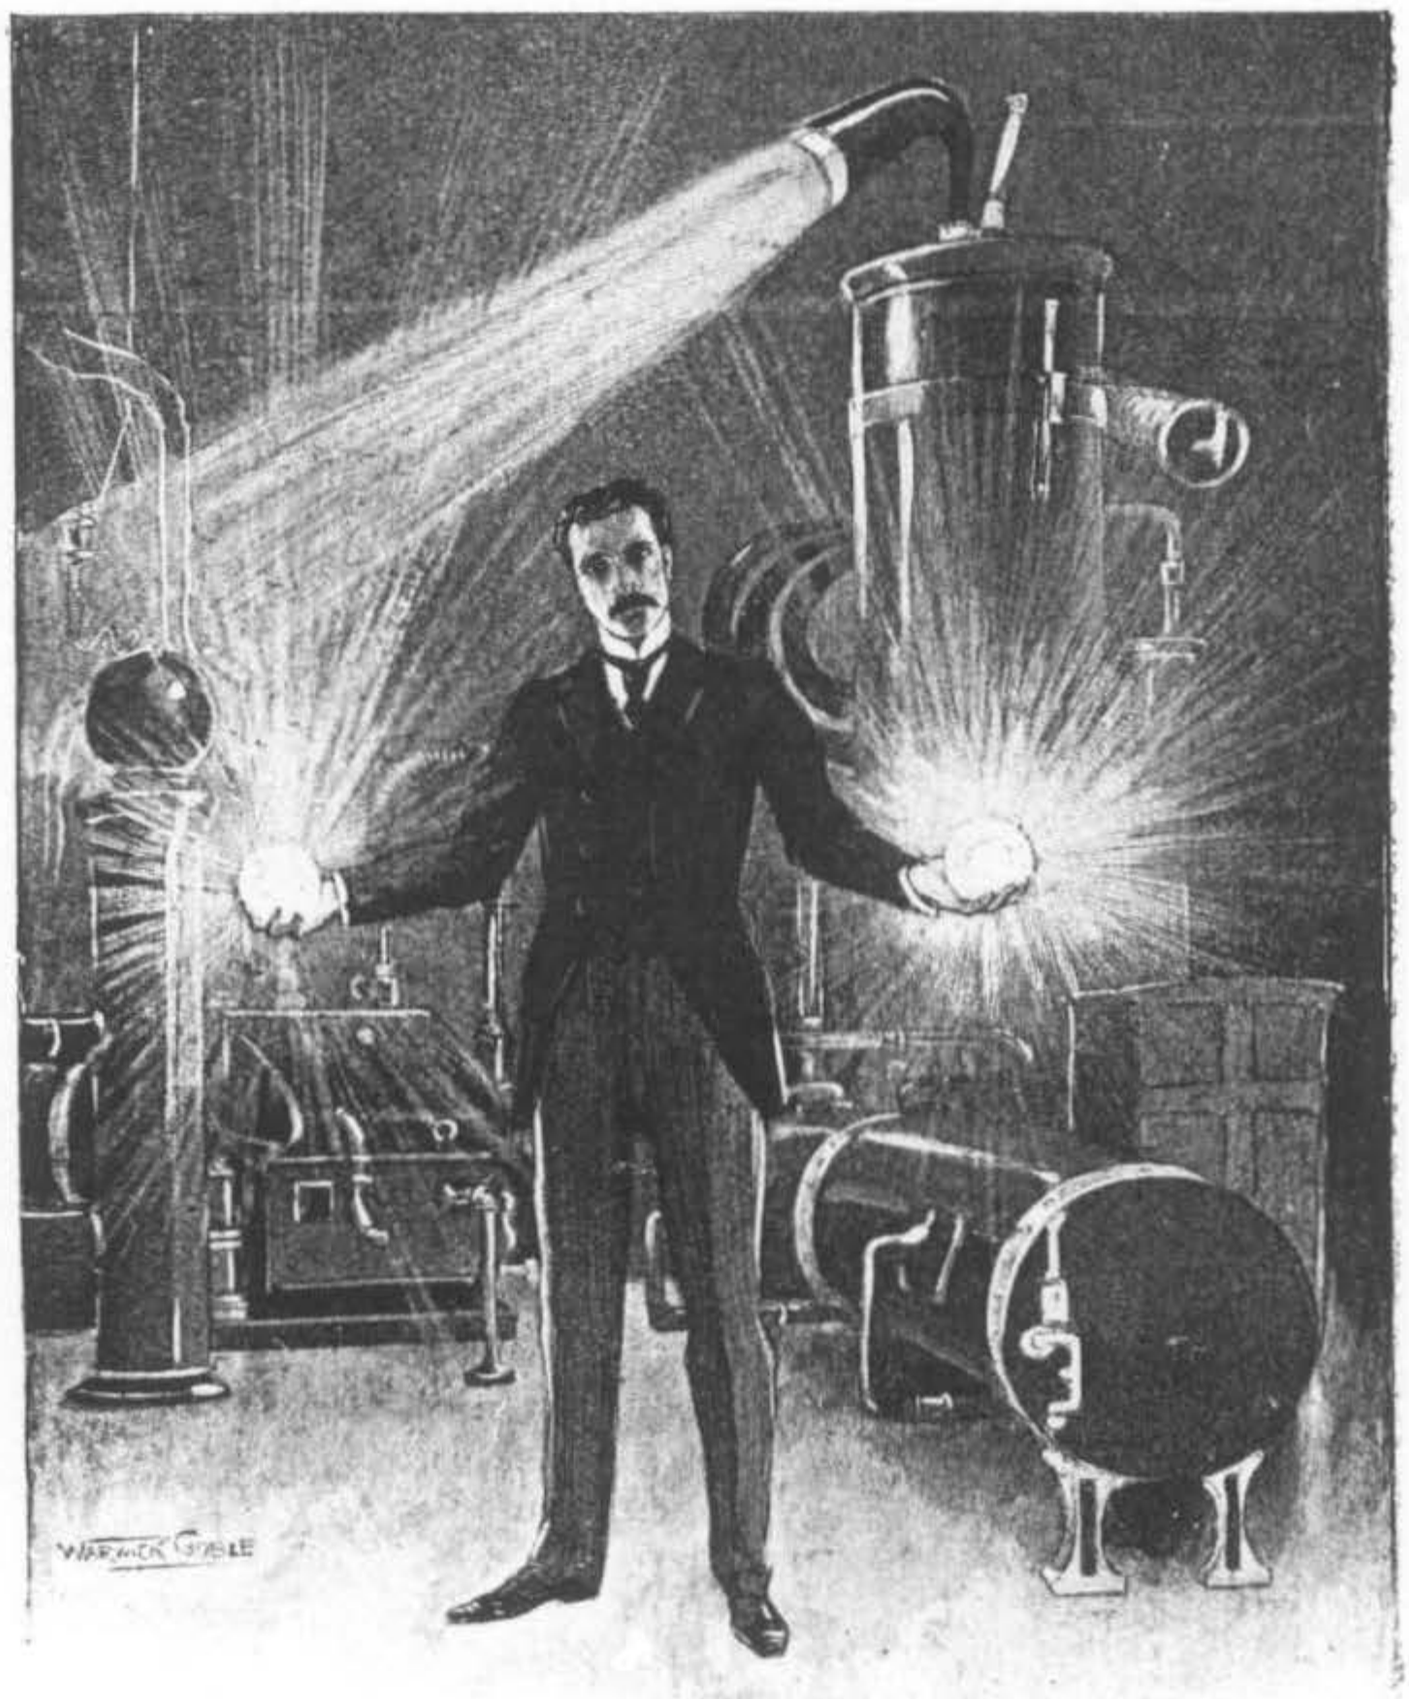
An Interview with Tesla, the Modern Miracle-worker, who is Harnessing the Rays of the Sun; has Discovered Ways of Transmitting Power without Wires and of Seeing by Telephone; has Invented a Means of Employing Electricity as a Fertiliser; and, Finally, is Able to Manufacture Artificial Daylight.

By Chauncey Montgomery M'Govern.

Not to stagger on being shown through the laboratory of Nikola Tesla requires the possession of an uncommonly sturdy mind. No person can escape a feeling of giddiness when permitted to pass into this miracle-factory and contemplate for a moment the amazing feats which this young man can accomplish by the mere turning of a hand.

Fancy yourself seated in a large, well-lighted room, with mountains of curious-looking machinery on all sides. A tall, thin young man walks up to you, and by merely snapping his fingers creates instantaneously a ball of leaping red flame, and holds it calmly in his hands. As you gaze you are surprised to see it does not burn his fingers. He lets it fall upon his clothing, on his hair, into your lap, and, finally, puts the ball of flame into a wooden box. You are amazed to see that nowhere does the flame leave the slightest trace, and you rub your eyes to make sure you are not asleep.

The odd flame having been extinguished as miraculously as it appeared, the tall, thin young man next signals to his assistants to close up all the windows. When this has been done the room is as dark as a cave. A moment later you hear the young man say in the laboured accentuation of the foreigner: "Now, my friends, I will make for you some daylight." Quick as a flash the whole laboratory is filled with a strange light as beautiful as that of the moon, but as strong as that of old Sol. As you glance up at the closed shutters on each window, you see that each of them is as tight as a vice, and that no rays are coming through them. Cast your eyes wherever you will you can see no trace of the source of the odd light.



Scarcely have you begun to marvel when the light goes out by a touch on a button by the young man's hand. The room is in darkness again until the same laboured accentuation causes the reopening of all the shutters. Some animal is now brought out from a cage, it is tied to a platform, an electric current is applied to its body and in a second the animal is dead. The tall young man calls your attention to the fact that the indicator registers only one thousand volts, and the dead animal being removed, he jumps upon the platform himself, and his assistants apply the same current to the dismay of the spectators.

You feel a creeping sensation course up your back, and you see the indicator slowly mounting up to nine hundred, and then one thousand volts, and you involuntarily close your eyes, expecting the young man to fall dead before you the very next minute. But he does not budge. Quickly the indicator goes up, up, up, until presently it shows that ten thousand volts, then two million volts of electricity are pouring through the frame of the tall young man, who does not move a muscle.

At a sign, the current is stopped, the room is again made dark as night, and presently the visitor sees the sharply-defined black silhouette of the young man, with a beautiful halo of electricity in the background, formed by myriads of tongues of electric flame which are darting out from every quarter of the tall, thin frame. The place is lighted once more, and as the young man comes up to you and shakes your hand, you twist it about in the same fashion as you have seen people do who hold the handles of a strong electric battery. The young man is literally a human electric "live wire."

To tell of these and a thousand other wonders that Tesla does in a trice gives only a faint conception of their effect on the visitor. To really appreciate them one must see, hear, and feel them in the flesh. It is a scientific treat of a lifetime, but it is a treat that few can enjoy, for the laboratory of Tesla is securely locked against everyone not provided with an introduction from a personal friend of the audacious wizard.

"Oh, pshaw! these are only a few playthings," Nikola Tesla replies when the visitor puts into words the astonishment he has experienced; "none of these amount to anything—they are of no value to the great world of science. But come over here and I will show you something that will make a big

Nikola Tesla holding in his hands balls of flame

Nikola Tesla.

U.S. Copyright by "Electrical Review," New York.

revolution in every business and home as soon as I am able to get the thing into working form," and then he leads the way through a forest of queer-looking discs and mysterious coils of copper and steel, until the party reaches a raised wall of masonry, on which reposes a long cylinder of glass filled with water, and surrounded by a circle of large mirrors. The roof over this apparatus is of glass, and as the sun pours its rays through this, the rays strike the mirrors and are reflected again towards the glass cylinder, magnifying glasses intensifying the heat of the rays before they strike the cylinder.

"This is the experimental model of the apparatus with which I hope some day to so harness the rays of the sun that that heavenly body will operate every machine in our factories, propel every train and carriage in our streets, and do all the cooking in our homes, as well as furnish all the light that man may need by night as well as by day. It will, in short, replace all wood and coal as a producer of motive power and heat and electric lighting."

The plan of Nikola Tesla to harness the rays of the sun to do man's bidding is probably the boldest engineering feat that he or anyone else has ever attempted. Though the idea is so great, its principle is so simple that a schoolboy can readily comprehend it. It consists of concentrating the heat of the sun on one spot (the glass cylinder) by the series of complicated mirrors and magnifying glasses until the resulting heat is something terrific.

This manufactured heat is directed upon the cylinder filled with water. This water is chemically prepared so that in a short time the water has evaporated into steam and has passed from the cylinder through a pipe and into another chamber. In the latter place this sun-made steam is made to operate a steam-engine of ordinary construction, the horse-power of which will be determined by the size of the apparatus by which the sun generates steam in that spot. This steam-engine is used to generate electricity. And this electricity can be either used at once or else stored up in storage batteries to be used on days when there is no sunlight.

It will be seen that the object of this plan of Tesla is to do away with coal, wood, or other fuel, in the manufacture of steam. The remainder of his invention calls for the use of this sun-made steam-pressure, as steam-pressure made from coal is at present in use

throughout the world. The advantage of this Tesla invention is that the cost of manufacturing steam to generate electricity, which would propel say one hundred tram cars, would be infinitely smaller than the cost of the coal required to produce the power to do the same work. The cost of manufacturing the electricity to operate these one hundred tram cars by the Tesla plan, when once the sun-station has been completed, would only be a sufficient amount to pay the salaries of a few engineers in charge of the sun-station.

"In this way electricity will be so cheapened," says Mr. Tesla, "that it will be possible for the poorest factory-owner to use it as a power at a smaller cost than steam. Electricity will in this way supplant steam as a motive power on all railways and—in the shape of storage batteries—on all water vessels. And the humblest citizen will profit by the new system of producing electricity; for he can have it in his home to do all his cooking and lighting and heating, and it will be even cheaper for him than coal, wood, or petroleum."

It is, of course, not the intention of Mr. Tesla that one sun-station will provide all the electricity for the whole world. His scheme is that in every city and town the local authorities shall build one or more of these sun-stations by public taxation for the use of the whole population, just as these cities now have waterworks and gas plants. Each factory and home will then get its supply of electricity from the nearest sun-station by ordinary electric wires.

Any person can appreciate the big boon that Tesla will confer on humanity by the early completion of this master task. Among other things it will solve a question that has been occupying the minds of scientific men for a long time, viz: "As the supply of coal in the earth will be exhausted in about a thousand years, what are we going to do for fuel?" It was when Tesla first thought about the question that he turned his mind to the invention of some form of making power that would not depend upon coal. The plan to harness the sun's rays is the result.

Quite independent of his scheme to harness old Sol, but yet capable of co-operation with it, is Tesla's invention to transmit electrical power without the use of wires. This consists of a means of generating electricity in one spot, where it can be done with little cost, and transmitting the electricity to some other spot where it is impossible to generate electricity except at a big outlay of money.

Of course, it is now possible to transmit electrical power from one place to another by the use of electrical cables, but the cost of these transmitting cables is nearly as great as would be the cost of generating the electricity itself in the locality to which it is desired to transmit it. By the use of Tesla's invention, the atmosphere takes the place of the electrical cables in the transmission of the power, and as the use of the atmosphere would be free, the cost of the transmission of electricity from one city to another would be merely nominal.

To make the atmosphere take the part of the costly cables, Tesla's plan is to erect large power stations at every spot where a great waterfall like Niagara, for instance, makes the cost of generating electricity only trifling when the apparatus has once been constructed.

Above each of the stations Tesla wants to build a high tower, over which will be suspended a large balloon. As the electricity is generated in the station below it is conveyed by cables to the tower, and thence to the balloon, where the electricity is set free into the atmosphere. As the atmosphere at this height is much rarefied, and as Tesla has demonstrated rarefied atmosphere to be a good conductor of electricity, the electricity which is thus set free will be carried on by the atmosphere to any indefinite distance.

The second part of the Tesla plan for transmitting electrical power without wires calls for the erection of receiving stations wherever desired. These will act as sort of receivers and storage houses for the electricity set free into the atmosphere at the generating station miles away. Over each of the receiving stations will be put up a tower and a balloon, which will be equipped with the apparatus necessary to absorb the free electricity in the atmosphere and send it to the receiving station below, from which it can be sent out on wires to light the surrounding

country and drive all the machinery of that particular district.

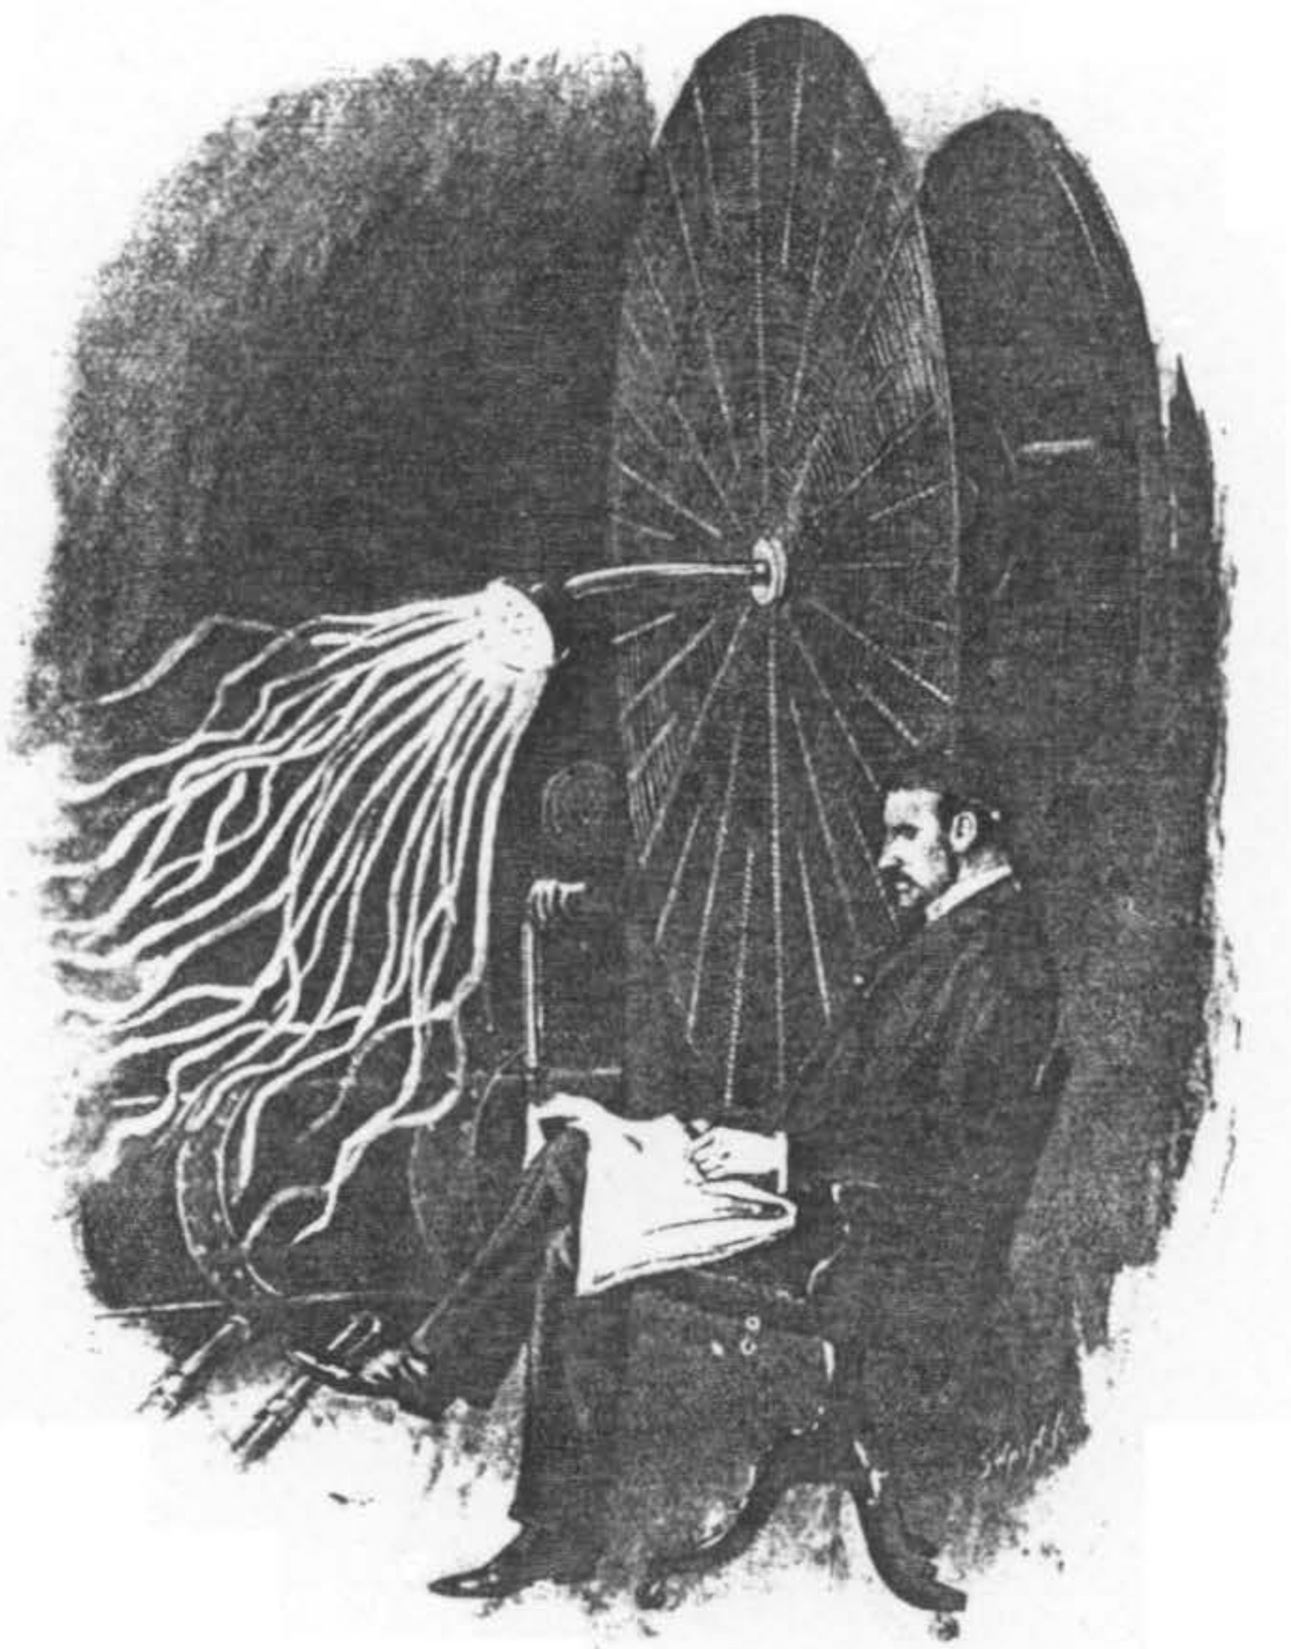
It will be observed that in this scheme Tesla depends on getting his electricity through the agency of the waterfalls, while in the previous scheme he depends upon the agency of the sun for the same purpose. But the inventor is far from believing that the two schemes will conflict. He believes that when both inventions come into popular use they will work together for the common good of man. "The agency of waterfalls to generate electricity could be used when that agency is most convenient in view of natural conditions," says Tesla, "and the agency of the sun could be used in all other cases. But my scheme of transmitting electrical energy without wires can be applied with equally good results to both systems."

Of all the great inventions which Tesla has well on the way towards that point where they can be given to the world for every-day use, his wireless telegraphy invention is the furthest advanced. All that is necessary now is the formation of a company to put up the public station. The principle of this invention is almost too well known now to bear extended explanation. Briefly described, it consists of constructing an apparatus to stir up the electric currents in the earth in such a way that their disturbance will be felt on a second apparatus fitted up in a different part of the world. Different disturbances of the electric currents produce correspondingly different impressions on the second apparatus —the receiver—and in this way an intelligible code is readily arranged.

For the benefit of non-scientific people the great inventor has described for me his wireless telegraphy invention in the following words:

"Imagine you have on a table before you an immense rubber bag snugly filled with water. I take a rubber tube with a piston-rod in it and insert the tube into the rubber bag. When I press on the piston-rod I compress the water in the bag so that it expands the bag.

"When I withdraw the piston," continued Tesla, "the bag will shrink just so much as there is water drawn up into my tube: and now if I put a second tube with a piston-rod into the bag at the other end, at every pressure of the first piston-rod the effect will be felt and measured in the second tube. Now if a certain action of one piston-rod indicates a certain word or a certain sentence, if you watch the other piston-rod carefully you may easily read it. This is exactly what takes place in wireless telegraphy," concluded Tesla: "let the rubber bag stand for the earth, the water for the electric currents in the earth, and the two tubes and piston-rods for a sending oscillator and receiving oscillator. One sort of disturbance by one oscillator means a certain sentence, and when this particular disturbance is recorded on the second oscillator the operator there knows exactly how to interpret it."



The "oscillators" to which the inventor refers are huge discs on which are insulated hundreds of coils of copper wire whose ends connect with the centre of the disc, where there is a huge round copper ball. They are really the only apparatus required for wireless telegraphy. To operate them Tesla simply turns the transmitting oscillator face downwards, and turns on a current which causes immense tongues of visible electric flashes to leap from the ball into the ground. The receiving oscillator has a delicate contrivance which throbs with each disturbance of the earth's electric currents and records them on a specially contrived apparatus.

Not the least fascinating of Tesla's numerous inventions is one to which he has given the name of "visual telegraphy." With this apparatus one person has only to look into the receiver of an ordinary telephone in one city, and, while talking to a friend a thousand miles away, he can watch the expression on the other's face, criticise the cut of his new suit of clothing, or advise him what to do for that tired look about the eyes. In this invention the experimental apparatus has proved thoroughly successful. The principle of this invention is that just as much as sound-waves make an impression on the immediate atmosphere, so do light waves make their impression.

"Now, as sound waves of the human voice are transmitted miles and miles yb the present telephone after their impression is made on the telephone transmitter," says

Mr. Tesla. "just so my experiments have demonstrated that the light waves of the human body can be transmitted by a different sort of telephone miles and miles away. All we need is the invention of a new transmitter. As the impressions of light waves are so many times more delicate than the impressions of sound waves, it follows that to transmit the impression of the human face, for instance, we require a transmitter many times more delicate. Now, selenium being an extremely sensitive substance, I have utilised this material in the construction of the transmitter which I have just described, and I have found it to be perfectly satisfactory."

To make our homes, our offices, and the streets at midnight as light as day, is another of the great tasks which Mr. Tesla set out for himself many years ago. His hope was to invent a new kind of electric light which would have the strong, steady glow of sunlight.

Nikola Tesla's wireless telegraphy apparatus.

That Tesla has succeeded in his dream to make artificial daylight there can be no doubt. To every visitor of his laboratory he shows numerous balls of glass of different sizes which look like miniature suns. The glass balls are perfectly empty, there are no wires in them, nor are there any wires on the outside of them. They do not burn the fingers when they are touched. The light does not hurt the eyes as sunlight and ordinary electric light do.

By the time this article is published, a number of the leading New York and Chicago photographers will have their studios supplied with the new artificial daylight.

"The reason I have chosen to introduce the new daylight to the photographers first," says the inventor, "is that I believe them to be the severest critics, and most hard to please in the matter of light. If it succeeds with them, a new light will succeed everywhere."

Not the least ingenious of Tesla's great schemes is his invention to fertilise impoverished land by electricity. When Tesla has a company formed to put this invention on the market it will no longer be necessary for the farmer to spend half his year's receipts in purchasing fertilisers. He has only to buy an electric fertiliser of his own, which he can secure for a trifle at the nearest town.

Dumping a few loads of loose earth into the fertiliser, it comes out at the other end ready to be spread over the surface of the impoverished ground, where it will insure for the following season the luxurious crop of the virgin soil.

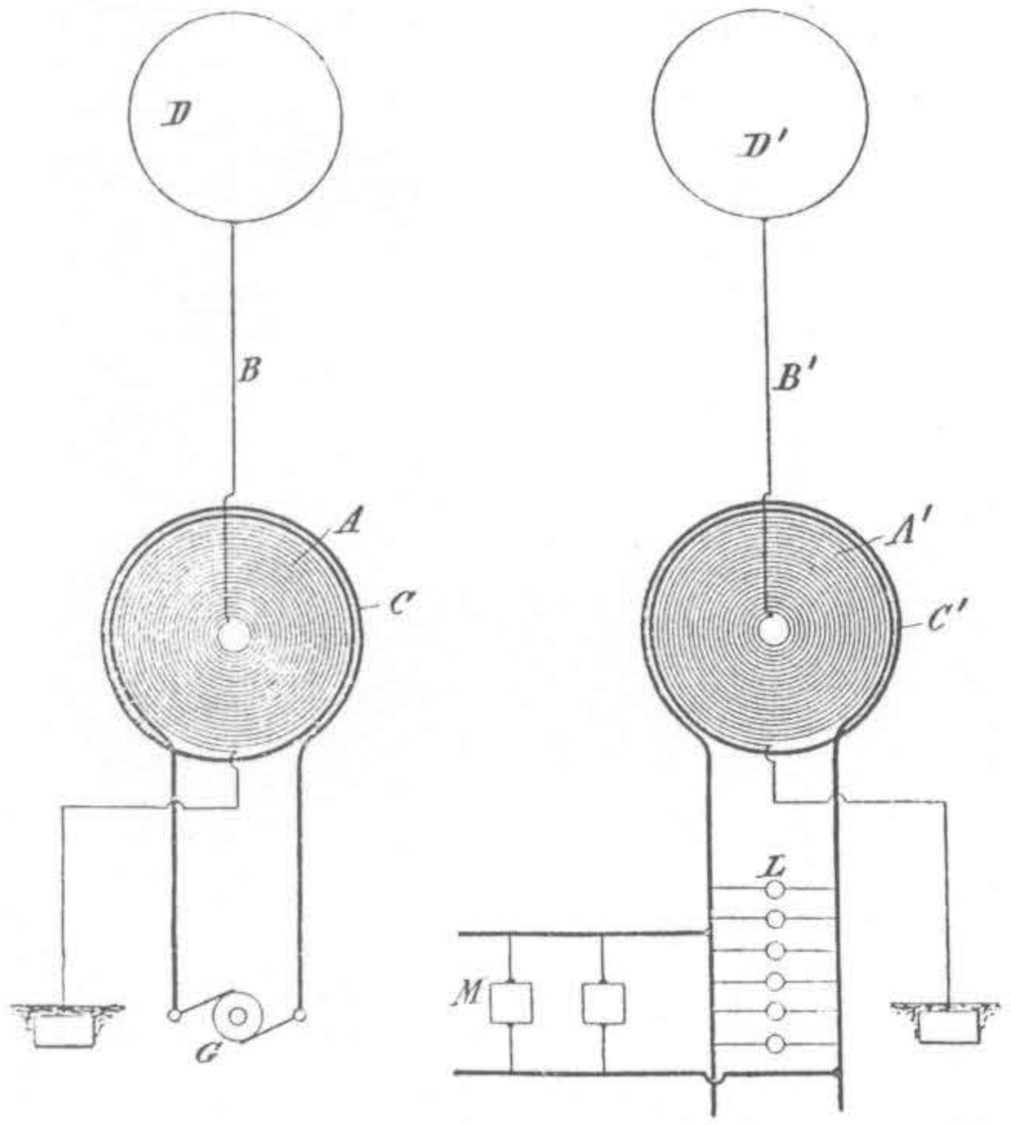
The explanation which Mr. Tesla gives of just why so simple a piece of work should be productive of such wonderful results is not difficult to comprehend. "Everyone knows," says he, "that the constituent of a fertiliser which makes the ground productive is its nitrogen. Everybody knows also that nitrogen forms four-fifths of the volume of the atmosphere above that piece of unfertile land. This being the case it occurred to me: 'Where is the sense in the farmer buying expensive nitrogen when he has it free of cost at his own door? All the agriculturist needs is some method by which he can separate some of this nitrogen from the atmosphere above the ground and place it on the surface.' And it was to discover this means that I set to work."

The hand of Nikola Tesla, taken by his wonderful artificial daylight, just perfected. This is the first photograph made by the light of the future.

As far as the non-technical eye can perceive, the working model of the electric fertiliser consists of nothing but an upright copper cylinder with a removable top, with a spiral coil of wire running throughout the length of the cylinder. Through the bottom of the cylinder are two wires, which connect with a specially constructed dynamo. A quantity of loose earth, treated by a secret chemical preparation in liquid form, is shovelled into the cylinder, an electric current is passed through the confined atmosphere; the oxygen and hydrogen are thus expelled, and the nitrogen which remains is absorbed into the loose earth. There is thus produced as strong a fertiliser for a nominal price at home as it is possible to purchase at a large cost miles and miles away.

Mention is made in this paper of only those inventions of Mr. Tesla which have passed beyond the experimental stage. But there are hundreds of other promised wonders in the yet incipient stage of development in the great inventor's miracle-factory. As I have heard one of his admirers express it, an enumeration of these "sounds like the dream of a half-intoxicated god." Signalling to other planets, raising of certain of the dead by electricity, ending all wars by a terrible machine—these are a few suggestions selected at random.

Nikola Tesla is a young man yet, and on this account many of his promises have been looked upon by older scientists as but fanciful dreams of a youthful mind. He has scarcely ever made any invention which the scientific world has accepted as possible on the first public announcement. But sooner or later the scientific wiseacres have been compelled to admit that Tesla has proven their theories to be wrong.



How these conservative scientists sneered at Tesla's "Utopian audacity" when he first suggested that man should harness the great Niagara Falls! But they humbled their pride sufficiently to be present when the enterprise was formally completed. Again, when he announced the invention of the "Tesla coil" they set him down as "pipe-dreamer." But a few of the brightest of them set to work seriously on the "coil," with the result that one of them—Röntgen—discovered his famous X-Rays.

No one who is privileged to know Tesla personally, to have heard him explain his plans, and to have been shown through his unique workshop, has the slightest doubt that every one of his promises will be fulfilled in an equally successful way.

ELECTRICAL REVIEW May 3, 1899 Vol. 34—No. 18

Suit on Tesla Patents.

In the United States Circuit Court at Philadelphia, on April 24, Judge McPherson heard argument in the equity suit of the Tesla Electric Company, of New York, against Gordon J. Scott and others, of Philadelphia, in which it is sought to have the defendants enjoined from the making of alleged infringements on the plaintiff's patented improvements in electro-magnetic motors.

Tesla's High Potential and High Frequency Work.—Fig. 1.

TESLA'S HIGH POTENTIAL AND HIGH FREQUENCY WORK.

Few inventors, in this last decade of a century of invention, have made a greater impression on the popular imagination than Nikola Tesla. Though by race a Southern Slav, he has now been settled for many years in the United States of America. From his race, it is to be presumed, he inherits his soaring scientific imagination, while from his environment he no doubt receives an extra stimulus to carry his fancies into practical effect.

Tesla, in the early part of his career, did some good work in connection with polyphase currents, but some 10 years ago he turned his attention to a comparatively new and unexplored field, namely, the production and utilisation of alternating currents of high frequency and high potential. Tesla's labours in this field have up to date revealed many new and startling phenomena, which, though they have as yet not found much practical application, may yet lead to the most astounding social and industrial revolutions.

A letter from Tesla, giving a sketch of his work and describing some recent experiments, appears in the *Electrical Review* (N.Y.), March 29th, 1899. From this and other sources we have derived the material for the following account of Tesla's investigations on the production of currents of extremely high potential:—

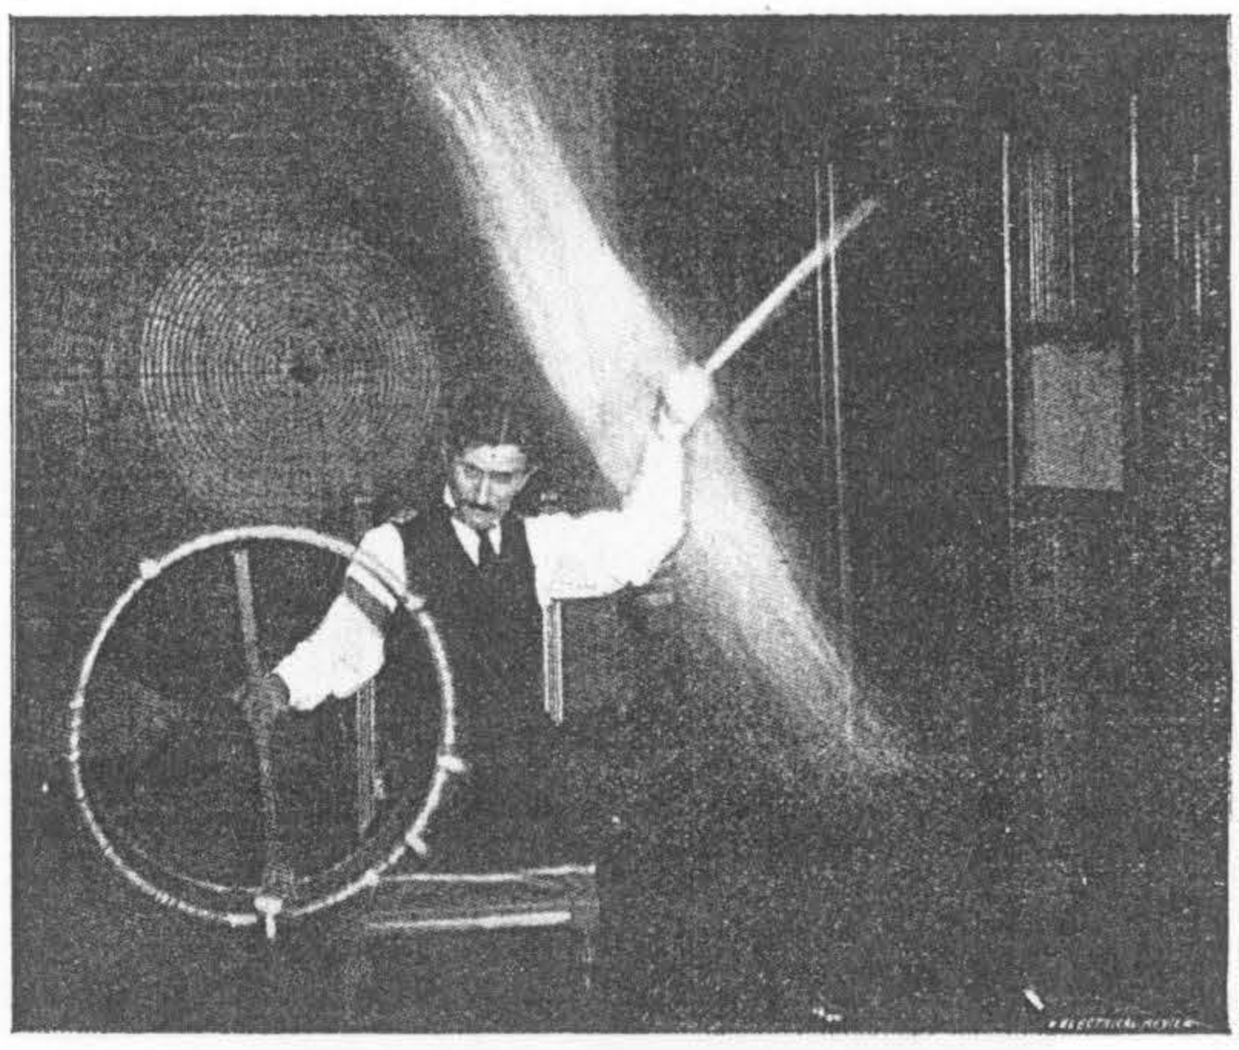


Fig. 4.—"Some Experiments in Tesla's Laboratory with Currents of High Potential and High Frequency."

The operator's body, in this experiment, is charged to a high potential by means of a coil responsive to the waves transmitted to it from a distant oscillator, and a long glass tube waved in the hand is lighted to great brilliancy by the electrical charges conveyed to it through the body.

At the beginning of his work Tesla found himself con-

fronted by three attractive lines of investigation; "there were the excessive electrical pressures of millions of volts, which opened up wonderful possibilities, if producible, in practical ways; there were the currents of many hundreds of thousands of amperes which appealed to the imagination by their astonishing effects; and, most interesting and inviting of all, there were the powerful electrical vibrations with their mysterious actions at a distance."

The production of high electrical pressures was finally chosen as, necessarily, the first step in the exploration of the whole field. Some attention was given to static electricity with the experiments of Franklin as a starting point. Various generators of static electricity were tried, and some new ones were designed. Tesla has not as yet published any account of these static generators which he has designed; it is to be hoped he will do so soon. The most valuable outcome of these experiments was the discovery of a method of operating any kind of low tension devices from such high pressure sources with perfect ease and safety.

Tesla, however, soon convinced himself that his object was not to be attained by the use of the steady pressures produced by static machines. "It was exactly," he says, "as if one attempted to drive piles into the ground by the application of continuous pressure. This would require cumbersome and powerful machinery, and would be very inconvenient. An incomparably better way of developing high pressure is by delivering violent blows as with a hammer." The kinetic energy of a hammer, when suddenly arrested, develops very high pressures, proportional to the rigidity of the body struck. In the same way, reasoned Tesla, enormously high potentials will be developed in the most convenient way by the electro-magnetic energy of a suddenly arrested current. This turned Tesla's attention to the use of transformers and induction coils for obtaining his high pressures. Those already in existence were evidently not adequate for the end in view, so Tesla set about improving them. First he tried the closed core transformer. This type was soon found to have several drawbacks; the insulation could not be made very high, and a very high frequency was impossible. Nevertheless, an arrangement of several of these transformers in series was devised, by which a pressure of 200,000 volts was attained. The secondary coils of several ring transformers were connected in series, while the primaries of all, except the first, were excited by insulated dynamos. This, however, was found to be practically a very inconvenient arrangement.

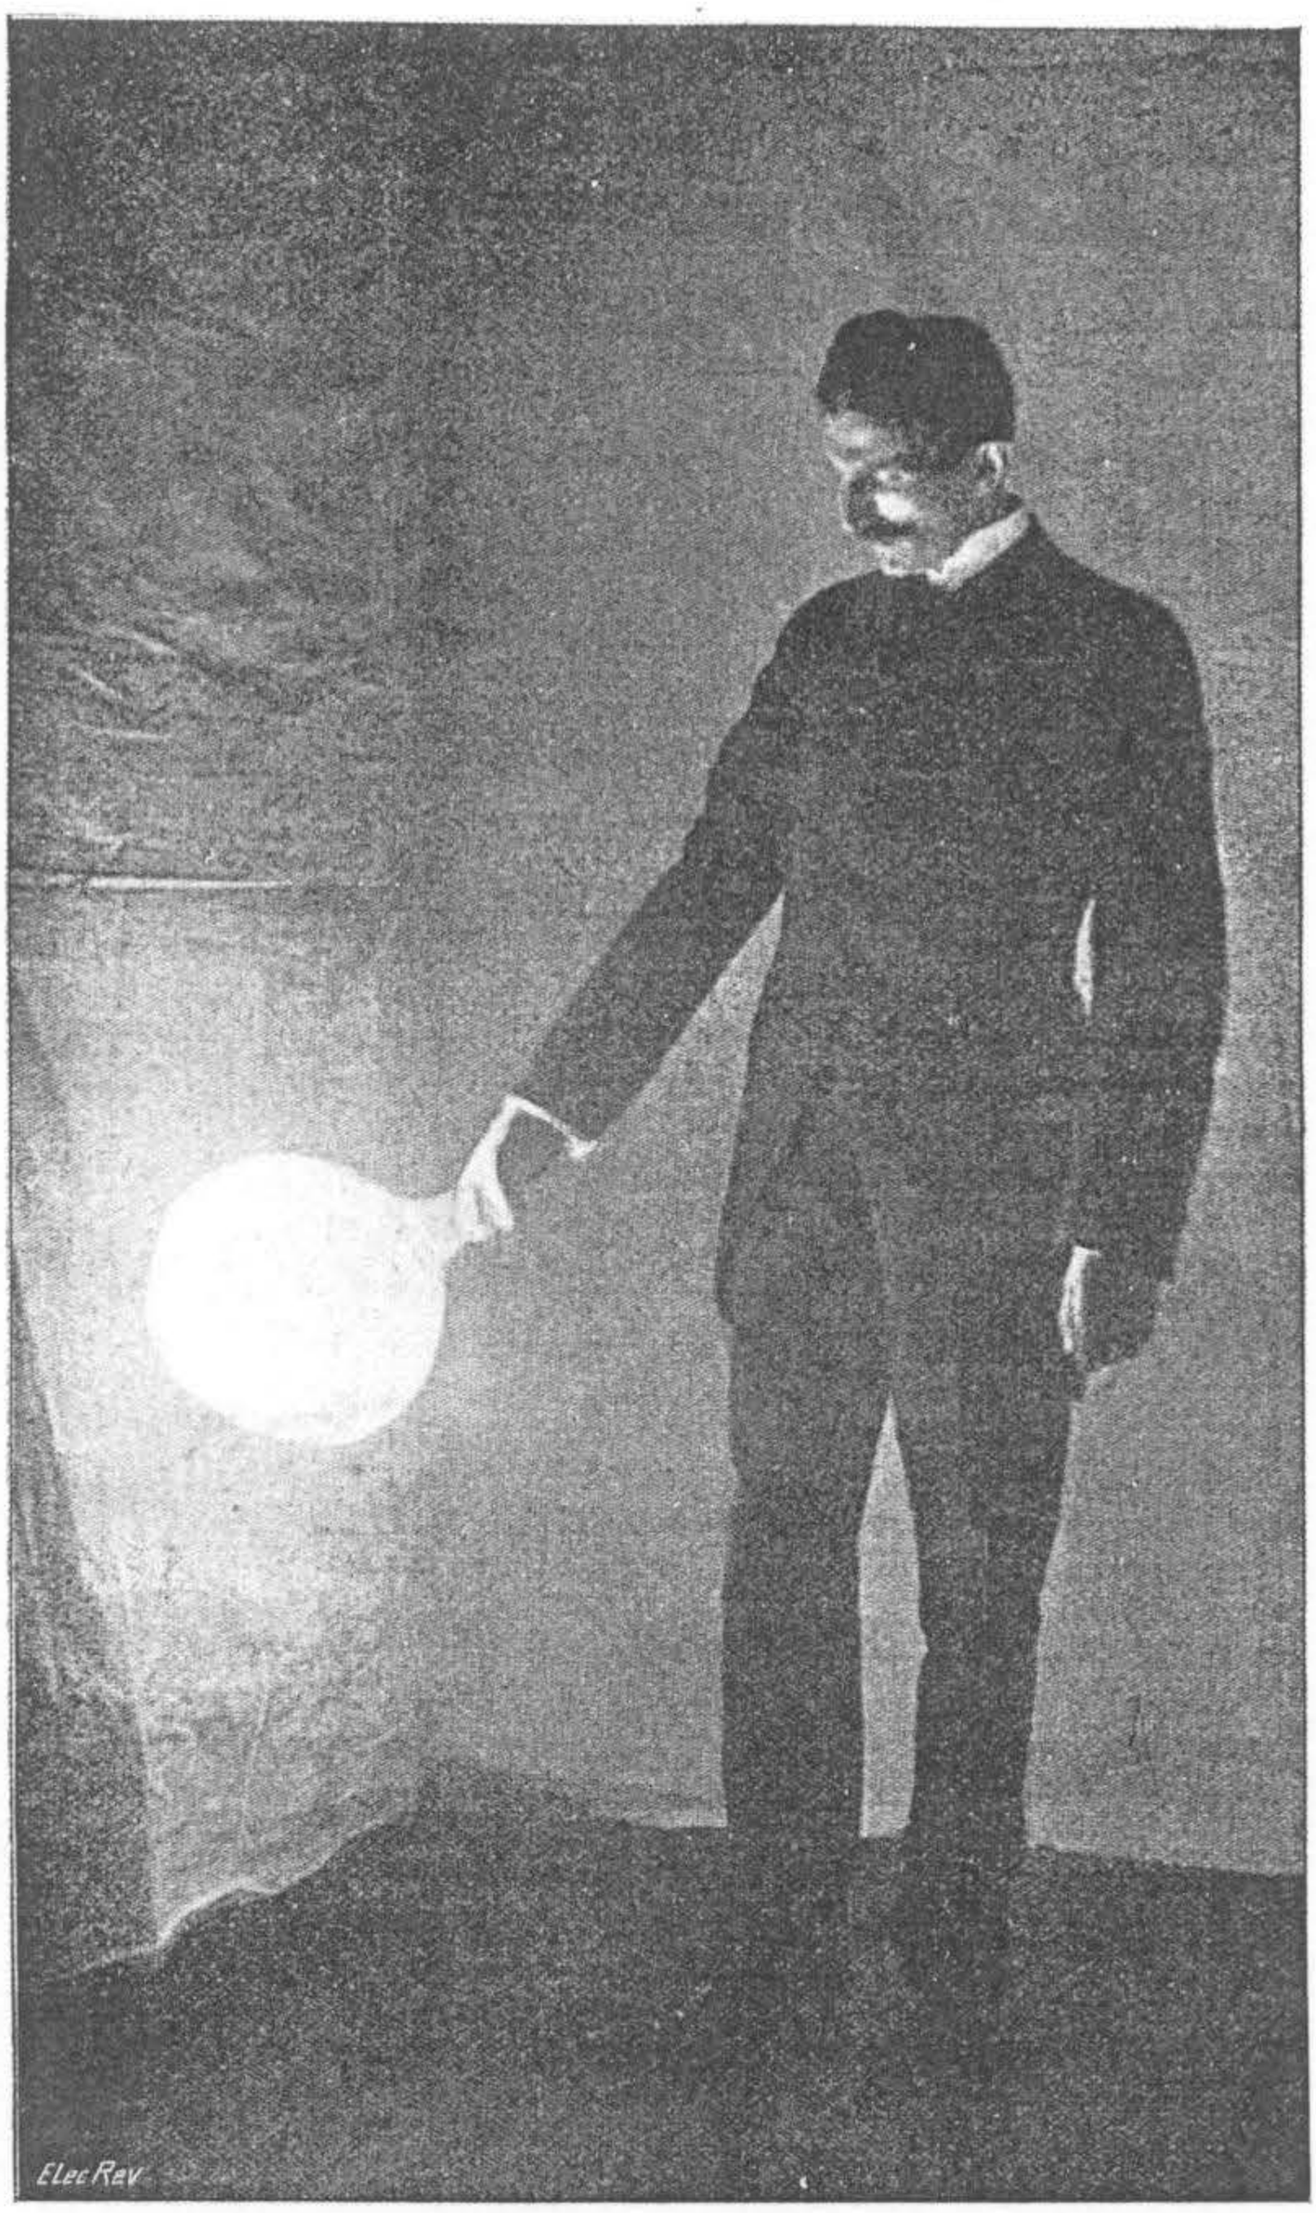

Fig. 2.—"Some Experiments in Tesla's Laboratory with Currents of High Potential and High Frequency."

Lighting a disconnected vacuum bulb of 1,500 C.P. by high-frequency currents—photograph taken by the light of the bulb itself, exposure about two seconds.

The straight open core type was then tried; several improvements in the insulation and arrangement of coils were tried, which appear to have been much the same as what has long been known to the makers of induction coils, such as winding in compartments, making the insulation thicker where a greater D.P. existed between adjacent parts of the coil, and so on. The first real advance made by Tesla appears to be his coil with a unipolar secondary. One terminal of the secondary wire is connected to the primary, the free terminal, as far distant as possible from the primary, being used for the discharge. A curious discovery made by Tesla in connection with this type of coil, was that the best results were got when the secondary wire was equal to a quarter of the wave length, as calculated from the frequency and velocity of light. This discovery Tesla has utilised in his most recent induction apparatus, with which he proposes to transmit electric currents through the air. It is difficult to explain this result; it appears as if something of the nature of a stationary wave of potential, with anode at the earthed terminal, was generated in the secondary wire.

During these experiments Tesla discovered that air played an important part in the breaking down of insulation, and by the exclusion of air, and the use of insulating liquids, he was able to increase the potential to 10 times the amount, without breaking down the insulation of the secondary. Tesla complains that the industrial world does not appear to have profited by the recognition of this discovery, since no attempt has been made to utilise it in cables for high potential transmission, to prevent streamers. It is a fact that the liquid insulation is less in favour in practice than when attention was first called to it by Tesla's experiments. It appears to have many practical inconveniences, and it is doubtful whether it is really superior to the solid insulation except for the high frequencies employed in the Tesla apparatus. An induction coil with viscous insulation was brought out a short time ago by Rochefort and Wydts,* and was said to be

* Electrical Review, 42, p. 165.

a great advance in efficiency, but it, like all the rest of such apparatus, has apparently dropped into disuse.

The final result of Tesla experiments with high tension generators was the coil or transformer illustrated in adjacent figure. In this coil the secondary coil is wound in a spiral lying practically in one plane perpendicular to its axis; its external terminal is earthed, and its length is made equal to a quarter wave length. The primary consists of a few turns of thick wire wound outside the secondary, lying thus adjacent to the part of the secondary whose potential is zero. It is with this apparatus that Tesla has made his experiments in the transmission of power through the atmosphere. The figure shows two transformers, a transmitter, and a receiver. The central terminals are connected to elevated plates, D, D', which require to be supported at a considerable height on a kite or a balloon. Tesla thinks a height of four miles will be sufficient. The air at such a height is supposed to break down under the enormous potentials developed, and become dissociated into a good conductor. This system of Tesla's has yet only appeared on paper, or, at least, no experiments on a large scale have been carried out in public. The criticisms with which this scheme was received when announced last November were by no means favourable. But Tesla is a pioneer in this field, and probably knows more about it than his critics. It is to be hoped that we shall soon see such a practical trial of his system as will finally determine its true value.

Tesla hints at a fearful catastrophe which might result from the introduction of his system of wireless transmission of power. The discharges of his coil when of an electromotive force of a few million volts, excite powerful affinities in the atmospheric nitrogen, causing it to combine readily with the oxygen and other elements, particularly in the presence of aqueous vapour. So energetic are these actions, and so strangely do such powerful discharges behave, that, says Tesla, "I have often experienced a fear that the atmosphere might be ignited." Can Tesla seriously believe in the possibility of such a calamity and yet go on with his experiments? Evidently the Tesla transformer is what Sir William Crookes wants to increase our supply of nitrates, and keep the wheat crop up to the demands of the world's increasing population; it is to be hoped Tesla's experiments will not solve the food problem in another way by reducing the population to zero.

The large size illustrations we publish show some remarkable results obtained in Tesla's laboratory by this coil. Fig. 2 shows a vacuum tube giving 1,500 C.P. illuminated by electric waves from a Tesla oscillator. Fig. 3 is a photograph showing a part of the laboratory with a disconnected resonating coil supported on an insulating stand, and illuminated by the streamers produced, other coils remaining unaffected. The pressure developed in the resonating coil is over half a million volts. In a similar experiment

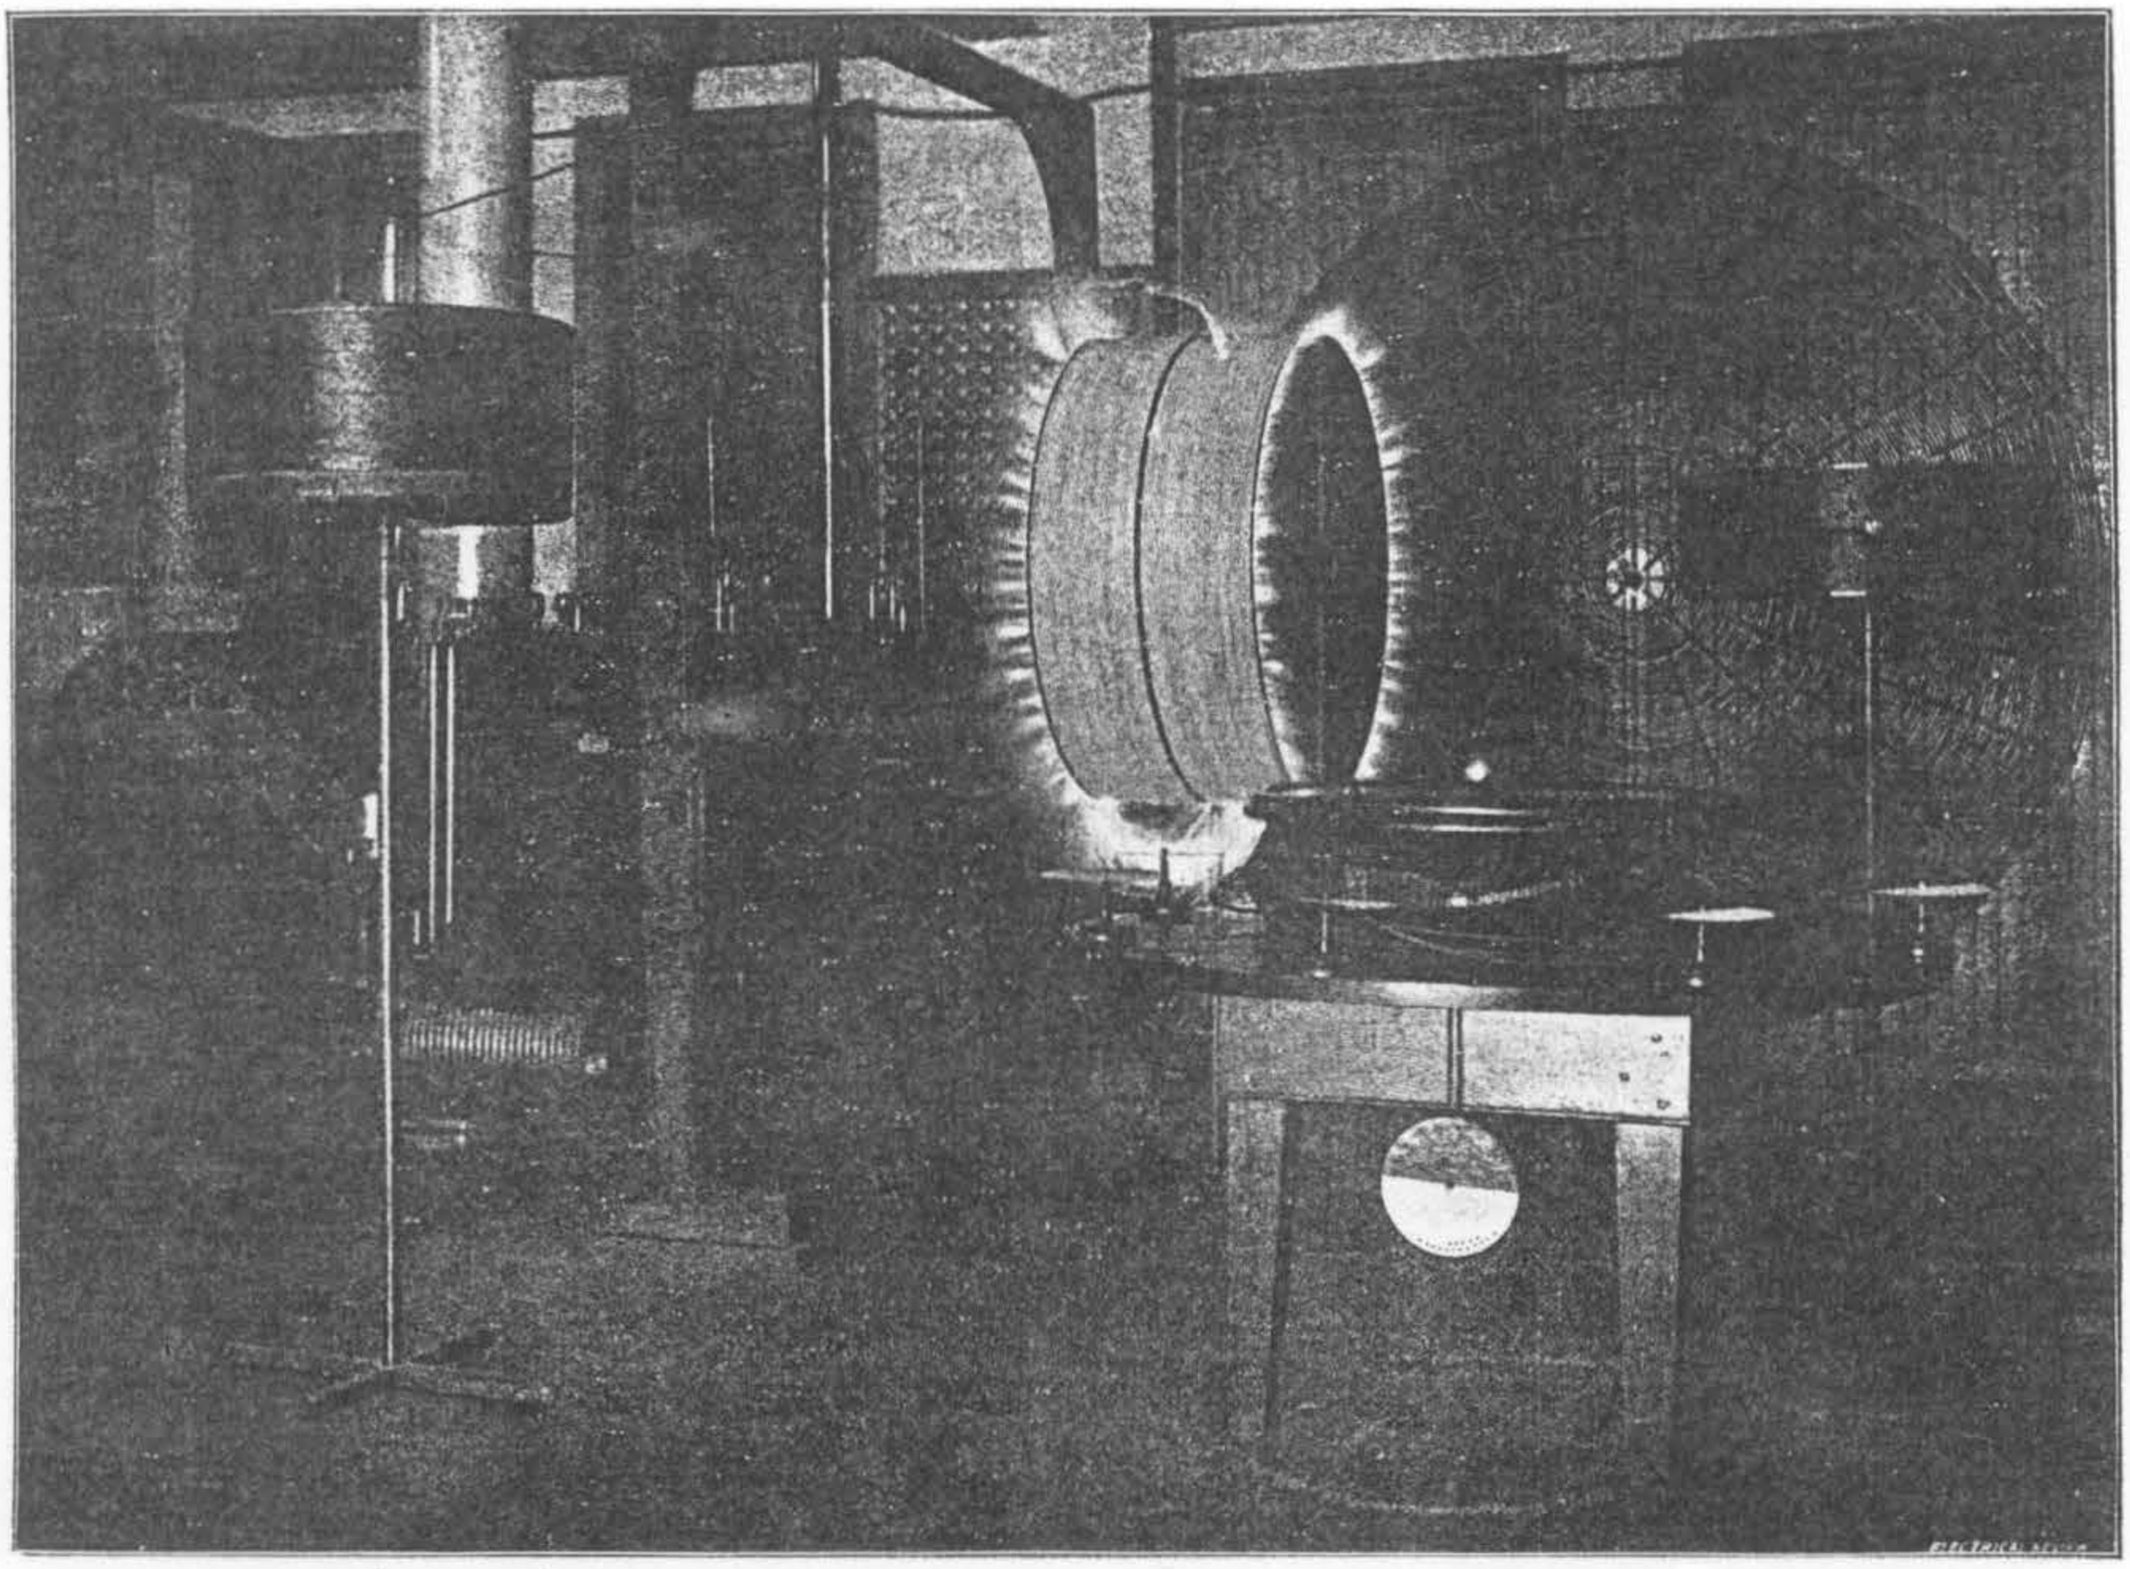

Fig. 3.—"Some Experiments in Tesla's Laboratory with Currents of High Potential and High Frequency."
Photograph showing a part of the laboratory, with a disconnected resonating coil supported on an insulating stand, and illuminated by the streamers produced, other coils remaining unaffected—the pressure developed in the resonating coil is over half a million volts.

Tesla grasped, without danger, a nodal point in a coil developing half a million volts. Fig. 4 shows a receiving coil illuminating a vacuum tube through the human body.

Very few details of the construction and operation of these latest fruits of Tesla's inventive genius have yet been published. For instance, we are left in the dark as to whether Tesla excites his high tension transformer by an alternating dynamo, or by a continuous current and a contact breaker. It is evident that lately he has been giving considerable attention to the latter device, in connection with an induction coil which has been exhibited in this country, and is generally known as Tesla's oscillator.

In 1891 Tesla patented a method of producing high frequency and high potential currents, in which an alternating generator sends currents through a primary, the secondary of which is in circuit with a condenser. This condenser lies also in a shunt circuit containing the primary of a second coil and a spark gap. The discharge of the condenser across this spark gap produces high frequency oscillations in the shunt circuit, and these oscillations are raised to an exceedingly high potential in a secondary coil wound round the

second primary. It was with an arrangement such as this that Tesla obtained the marvellous results which he showed before the Institution of Electrical Engineers at the Royal Institution in 1892. The discharge from his apparatus appear to penetrate with ease the best insulators; electrodeless vacuum tubes were illuminated at a distance of several yards from the poles of his coil; unipolar lamps gave out a light of dazzling whiteness, but unfortunately of very small candle-power. It appears to be one of these unipolar lamps that is held in Tesla's hand in fig. 2. If so, very considerable progress has been made since the Royal Institution lecture in 1892.

It is a coil of the above type that is generally used for producing Tesla currents for electro-medical purposes. Their use for certain purposes in electro-therapeutics is said to have been highly successful. It is a curious fact that such discharges of a potential of tens of thousands of volts can be passed through the body without any injury. A satisfactory explanation of this strange phenomenon has not yet been given; it has been suggested that it is because these rapidly varying currents must be purely superficial; it may, perhaps, be due to the fact that such currents are almost completely wattless, owing to the displacement of phase between the current and the electromotive force being almost a maximum.

In 1896 Tesla patented an improved generator of high frequency currents, which is known in this country, at least, as Tesla's oscillator. The spark gap in his first type of generator was replaced by a mechanical contact breaker, and the arrangement of the circuits was somewhat different. A condenser is connected in shunt in a circuit containing a continuous current generator, choking coils, the primary of the coil, and a contact breaker. When the circuit is closed by the contact breaker a direct current flows through the circuit. The circuit is then suddenly broken, and the condenser is charged to a very high potential by the self-induction of the choking coils. The contact breaker again closes the circuit, and the condenser discharges through the primary, which, being of few turns, has a comparatively small self-induction. The result is, that the frequency is considerably higher than in the ordinary induction coil where the choking coils would form part of the primary coil. This oscillator has been shown more than once in this country; it can be worked from lighting mains, and its working appears to be highly satisfactory.

It is apparently in connection with this oscillator that Tesla has devoted himself to the improvement of the mechanical contact breaker. In his original patent for the oscillator (No. 20,981, A.D. 1896) he describes a rotary contact breaker, which creates by its motion a current of air about the contact points, with the view apparently of removing the dissociated air, and improving the insulation of the spark gap. It is in a more recent patent (No. 12,866, A.D. 1898) on electric circuit controllers that we find embodied Tesla's latest discoveries in this field. The contact breakers there described are mechanical, of a very elaborate construction; too elaborate, we should think, for general use with induction coils, unless their superiority to the present simpler forms is very great. Two new ideas appear to be embodied in these interrupters; first, the break takes place in compressed air or other suitable gas, and second, a jet of mercury discharged against a metal plate, or another jet of mercury is used to complete the circuit. The metal plate is rotated by an electro-motor, and is notched on the periphery where the jet of mercury impinges, so that contact is broken when the jet passes through one of the notches between the teeth. Tesla has expressed a somewhat ungenerous contempt for the Wehnelt break, which has recently given such remarkable results in the hands of experimenters here and abroad. Its inferiority to Tesla's break appears to be known as yet only to Tesla; in simplicity, at least, it is certainly superior.

We, however, wish Tesla success in the working out of his grandly conceived, and if realised in practice, undoubtedly epoch-making ideas.

TESLA AS "THE WIZARD."

EXPOUNDS ELECTRICITY AS THE GUEST OF COMMERCIAL CLUB.

Astounds His Hearers with Predictions of What the Subtle Fluid May Yet Accomplish in the Arts and Industries and Thrills Them with Demonstrations Along the Line of His Novel Experiments—Work of His Oscillator—Wireless Torpedo.

Nikola Tesla was introduced to the members of the Commercial club last night as "the magician of the electrical world." Mr. Tesla then proceeded to astound, if not appal, his auditors by telling them of the things he would do when he had completed his devices for making Niagaras of nitric acid out of the atmosphere and converting what remained of this breathing material into a substance for the transmission of light and heat and power around the world.

Among Those Present.

Among those present were:

Some Remarkable Tests.

Mr. Tesla talked at length and illustrated what he said with demonstrations made with his invention of a wireless submarine torpedo, his oscillator, which it is promised will transmit power across the Atlantic without wires; and several other devices which contributed almost as much to put his hearers into a state of bewilderment and amazement.

One of the astounding things he did was to fire five guns on board a wooden torpedo boat, work the rudder at will, and start and stop the screw propeller by electric impulses transmitted across the room without wires—something which already had been done in New York, but which never had been seen in Chicago. It was this experiment which mystified the scientists present, as well as the Commercial club members, though some of them declared the mystery was wholly in the mechanics and not in the electricity.

Mr. Tesla displayed another of his discoveries before attempting the experiment with the torpedo boat. His scheme for creating light in vacuum tubes by "jarring" the molecular atoms inside was displayed to the wondering business-men by lighting the room with bright flashes of blue light. The tube was held and waved about in the air by various members of the Commercial club. There was no wire connection in this experiment, though the electric current was transmitted through the body of the person who held the tube.

Developing "Electrical Sense."

Mr. Tesla did not reach his most interesting experiments until almost midnight. Just before he began handling his apparatus he declared that, to his mind, human beings were developing an "electrical sense." In his own experience, he said, he had found himself intuitively shunning destructive electric currents, and he believed that ultimately a sense would be developed as strong as the "sense of gravity."

Then the vacuum tubes were taken up. The test with these which excited most interest was made with an ordinary glass tube about four feet long, exhausted to a vacuum and hermetically sealed at both ends. Connection was made with the oscillator and ground wire by holding a pair of steel nippers against one of the poles. The glass tube was held in the other hand, and when the current was turned on the interior of the tube glowed with an uncanny blue light that almost filled the room.

First H. H. Kohlsaat held the tube and swung it around his head. The lights having been turned out the vacuum tube lighted the room like a chandelier. Harry G. Selfridge and Mr. Tesla himself then swung the tube. Then Mr. Selfridge tried the experiment of running his hand up and down the tube while some one else held it, and it was discovered that the portion of the tube beyond his hand scarcely glowed at all, while the uncanny blue glow seemed to extend with his hand in a bunch.

Mind and Matter.

Mr. Tesla declared he believed that many so-called mental phenomena could be accounted for on physical grounds. He believed, he said, that it was only a question of time until suitable scientific instruments would be invented that would read people's minds.

Before trying the tests with the torpedo boat model Mr. Tesla declared that the system of transmitting signals without wires between two transmitting spheres (the Marconi wireless scheme) was his own and that he had discovered the method in 1893. "With other methods you need ten times the power for ten times the distance," he said. "With the discovery of mine distance makes no difference."

President McCormick made the only other speech. When the dinner was finished he announced there would be an intermission of ten minutes. During that intermission Mr. Tesla held a little informal levee. Members of the club crowded around the tall, angular man, whose slight black mustache, raven hair, and sallow complexion heightened the effect of his air.

President McCormick's Introduction.

After the intermission President McCormick introduced Mr. Tesla, saying:

"We shall be much interested to hear from Mr. Tesla of the realm in which he dwells, which seems to us so incomprehensible, and if we become puzzled at the relative importance of 'ampères,' 'volts,' 'ohms,' 'induction,' and 'polyphase currents,' Mr. Tesla must remember that, although we may know more about other things, we are still in the primary class in electricity.

"Since this great force of nature has been made subservient to the will of man, electrical progress has opened a wide field for both capital and labor. The Commercial club will be interested in knowing that in this country alone the capital employed in the manufacture of electrical apparatus is $50,000,000; the telegraph interests represent $100,000,000; the telephone systems $110,000,000; while the investment in electric lighting is $247,000,000; this statement does not include the electrical equipment for elevated or surface railways.

"If this is the position which applied electricity holds today, who can say what its limit will be in the future? When the power of Niagara's thundering tide shall be moving the looms of New England; when 'ships that pass in the night' shall telegraph messages to each other from distant horizons; when Tesla's 'oscillator' shall be sending electrical currents from the top of the Alleghenies to turn the shafts of the Paris exposition of 1900; then may we stand in awe as we realize what secrets the mind of man has wrung from these latent forces in nature, and we may exclaim with Morse in his first message sent over the telegraph wire, 'What hath God wrought?'"

Mr. Tesla talked in a low voice and with a defective accent. These two characteristics of his delivery prevented him from being as fully understood at all times as he might have desired. His first demonstration was of the force in what he called a simple piece of iron with a coil of wire around it. There were two of these, looking alike, about eight inches in height and consisting of a pedestal surmounted by a circle. To one of these he held a disk, which was fixed on an axis in a handle. The disk did not show any effect. He held it to the other and the disk whirled. It was colored black and white, so everybody could see that it whirled. That was done, Mr. Tesla said, to illustrate the statement he had just made that some things are animate and some inanimate. He said those that are animate have life and that iron may be animated and be therefore deserving of a place in the list of things science has declared to be living objects. The iron was connected by wire with a dynamo and the current was turned into it, when it showed its quality of "life."

He then declared it was not beyond hope that it would be possible to deprive matter of its latent powers, its heat, and its consequent energy. When that was done and absolute zero obtained the present wonders of the electrical world would look insignificant.

Work of the Oscillator.

Then he turned to the task of his oscillator. He said that in order to transmit force from one object to another there must be something between them. It might be something so attenuated that it was not easy to comprehend it, but it must be there if the energy is to be transmitted.

He said he had succeeded in converting a column of gas into a solid column with the rigidity of steel.

"I have produced a flame which offered resistance to bodies," he said. "It resisted their passage through it. That is an approach to solidity. I may yet produce at the end of a wire a solid body."

He then told of a method he had invented for the production of ozone, which could be made in commercial quantities for sterilization and for purposes of sanitation. It was made by the process he followed in the production of this flame which had the power of resistance.

Forces of the Air.

"The forces of the air may be utilized in a manner now that we have not learned to even contemplate. Nitric acid may be made from the components of the atmosphere."

"This nitric acid may be made to fill our reservoirs and then utilized to produce the energy we need and to transmit energy to almost unlimited distances."

His greatest invention, he said, was in utilizing the forces of the air.

"The air, which is an insulator," he said, "becomes a conductor by means of the millions of volts I am able to produce. It means the using of the air for all purposes and uses of men. Not only for the transmission of messages without wires, but for the transmission of power in any amount to any distance across the earth's surface."

Views of Scientific Men.

Not all the scientific men who saw the tests agreed with Mr. Tesla as to their practicability.

"Mr. Tesla has certainly worked out the mechanical details of the torpedo boat apparatus to perfection," said Arthur V. Abbott, chief engineer of the Chicago Telephone company. "But there is too great a waste of power for it to be utilized for more than a few feet. The apparatus would be absolutely useless from the Auditorium to a boat a few feet from shore in Lake Michigan. There is nothing new about it except the mechanical adaptation. It is the same coherer that Marconi uses, only Tesla's revolves instead of being hit by a small hammer. The vacuum tube lights may have some commercial value, but it has not yet been discovered."

Professor Jerome J. Green of Notre Dame University and Professor Carhart of Michigan University both looked skeptical when asked their views of the experiments. Each said:

"I should want to have him explain his 'sensitive' apparatus before I made any comment on the newness of what he has shown."

TESLA'S TASK OF TAMING AIR

The Inventor's Hopes of Building Fame on the Establishment of a New Art.

GREAT FORCE HIS TOY

Wants to Make Nature World's Utilitarian Agent.

TALKS OF SIGNALING MARS.

Transmission of Intelligence Feasible Assuming Equal Conditions Exist on the Other Planet.

NIKOLA TESLA has come to Chicago. One afternoon of busy work with his machinery, a lecture in the evening, a day of social visits. That was all. To-day he leaves for Colorado, where his busy mind will continue to work in the same channels as it follows when he is at home in New York.

But Chicago is left full of wonder. "What of Tesla?" is the question which everyone must ask who has come into contact with the man and been made to feel with personal force something of the scope of his ideas. That he lives in high regions of an atmosphere totally unfamiliar to practical Chicago business sense everyone must recognize. But whether it is an atmosphere of phantasma, bubbles, specters, or whether it is the breeding place of things all important for the practical world of the future, that is the question.

Belittles His Experiments.

It is a question which each man can answer as best suits his own disposition. Indeed to Tesla himself it is indifferent whether it is answered at all or not. But when he was approached yesterday by a reporter for THE TIMES-HERALD and asked questions about the nature of his work and its bearing on human affairs, he consented to talk quite freely. He said many things that throw further light upon his lecture of the night before, as well as having interest as expressions of a character unique among the men of genius of the day.

From what he said it was very clear that for him the little experiments he had performed at the dinner of the Commercial Club were simply trifling applications of the principle he is working out in his investigations. That he could transmit force to some distance without the use of wires, that he could make lights glow and wheels revolve and torpedoes explode without any contact with them except through the medium of air, was wonderful enough to the men who saw it. It filled their attention, for it was specific and immediately present.

But One Problem Before Him.

But to Tesla himself, however much pleasure he may have taken in seeing his experiments work so successfully, it was only a little illustration of one of the simplest forms of communication and transmission of power which he says he has discovered and become able to control.

This great problem, the transmission of force in quicker and more precise and more effective and economical ways, is the center of all Tesla's speculations at the present time. It has long been the great problem set by him for solution.

"The invention of the torpedo boat worked at a distance," he says, "and the discovery of the principles of wireless telegraphy are simply incidents in my progress. They are not ends which I deliberately set out to accomplish. For many years I have given myself over, to the problems involved in communication between individuals at distances and in the transmission of energy from one place to another. There are methods for these things which are as old as the human race, and there are others which are comparatively new.

Wants Fame for Something New.

"None of them is as effective as it might be. I have discovered other ways of transmitting force, and some of them are capable of great development. They will tend to revolutionize the human race in many of its doings.

"What I am doing is to develop a new art. Is that not more important than the attempt to elaborate an old art in some of its phases? I want to go down to posterity as the founder of a new method of communication. I do not care for practical results in the immediate present. Where I have time I stop to develop the application of the principles that I have announced, but that is a part of the work which it is usually safe to leave to others. They will do it because there is money in it. For myself I am content to find the new principles through the knowledge of which the applications become possible."

Suggests the Wizard in Face.

Tesla's bright eyes glowed as he spoke of his ends in his work. Leaning forward, peering almost each moment into the eyes of his interviewer to make sure that his meaning had been understood, he proved a talker from whose train of reasoning there was no escape while a man was under his influence. With close cropped mustache, high cheek bones, clean shaven face showing all over the signs of a beard struggling to assume complete control of his appearance, he is a man whom only the addition of a pointed beard would be needed to turn into a typical Mephistopheles.

He turned aside from his statement as to his general aims to answer some questions put to him about the agencies which he has developed for communication with Mars or any other planet. That is another application of his theories about ways of transmitting force.

Signal Can Reach Mars.

"Signaling to Mars?" he said. "I have apparatus which can accomplish it beyond any question. If I should wish to send a signal to that planet I could be perfectly certain that the electrical effects would be thrown exactly where I desire to have them and that the exact signals I desire to make would be made. Further than that, I have an instrument by which I can receive with precision any signal that might be made to this world from Mars. Of course that is not the same as saying that I could establish communication with beings on Mars, but if they should know that I was signaling them, and had intelligence approximately similar to ours, communication would not be impossible."

Then Tesla began to explain the difference between his methods and those that might be suggested at first hand for sending a signal. "Suppose," he said, "a ray of light should be sent out toward Mars. It would send its beams in all directions and only a very slight proportion of the energy would fall upon any particular spot on the planet. If there were sensitive enough instruments there that infinitesimal bit of force would affect them. But in order to make the sending of signals practicable what is needed is a way of condensing energy. It is thus that I have found out how to do, and for this I possess the proper instruments already.

Receiver and Sender Needed.

"Two sets of instruments are necessary—one of them to send, the other to receive. My oscillator is used to send out the electrical vibrations, and I have an exceedingly sensitive mechanism which I call the rotating brush to receive signals. By the use of 10 horse power with any oscillator I would be able to start the entire electricity of the earth in vibration and secure sufficient strength to take effect on an ordinary fine relay on Mars. The amount of electricity needed to affect a relay is perfectly well known. By the aid of astronomical data I have calculated exactly what is necessary to secure the desired results on another planet. I can send out in this way force amounting to a trillion times as much as could be sent from a 100-foot reflector, if such a big one could be made to send rays of light into space.

"Now, on the other hand, there is the receiving of the signal. This is accomplished by the rotating brush, which is incomparably the most sensitive device known to science. I described it in my lecture before the Royal Institution in 1892.

Gathers All the Force.

"Heretofore only a minute amount of energy falling on a planet from another would fall upon and affect the receiving instrument of whatever kind it might be. Now, through my device the entire amount of the energy falling on the receiving planet can be gathered together and made to take effect on the instrument which receives the signals. The sensitive instrument will harness the entire electricity which the planet gets. The calculations are exact and beyond question.

"There you have all that is needed for the sending of signals from one planet to another. The difficulty was to get enough force upon a given spot to make the signal marked enough to be appreciable. The two instruments I have described overcome all this difficulty."

Mr. Tesla has not yet attempted to signal to any point so far away as Mars, but he is using these very same instruments in other modifications in signaling between different parts of the earth. They are similar in many ways to the instruments which he used Saturday evening before the Commercial Club to transmit power the little distance across the room without the aid of wires.

Transmission From India.

The principle is the same. He says that his sensitive rotating brush, as he has it in operation in his laboratory, will detect any electrical disturbance or sudden physical commotion which occurs in any part of the planet. A sharp electrical storm in India would be made known to him, he says, by vibrations of his instrument.

When asked what particular problem was occupying his attention most of all at the present time Tesla said: "I am striving to find out the best means of getting power from nature. The use of waterfalls to develop electricity which can be conducted through the air to the places where it is needed for practical use is one of the sides of the investigation. There is still another method I am struggling with, but I would say anything about it. It is older in my thought than the electrical method, but harder to work out and much less developed.

"Central in these problems of the transmission of force is the use of air as a transmitter. I told in my lecture how by the application of tremendous pressure through an exceedingly high voltage of electricity I could turn air from an insulator to a conductor. I can make it act toward the power I want to transmit just like a copper wire."

Great Resources of Air.

Mr. Tesla could not say too much in enlargement of his opinion expressed in the lecture that the coming century would bring the world into what might appropriately be called the era of the atmosphere. He is a wonderful optimist in his way, believing implicitly in man's ability to attain all his ends with ever increasing effectiveness, and in the air he sees the factors which will rapidly be developed to make up for all the threatened deficiencies in other parts of the material environment, such as in the timber and coal supply. Out of air will come, he predicts, the food of the world. Through it all power will be transmitted. It will be the vehicle for the spread of intelligence and of energy. Persons will begin to transport themselves through it in flying machines. Finally by the process of liquefaction much may be accomplished for science and for industry.

In regard to the air as the source of the world's food supply he said: "I have discovered a form of electrical discharge which excites the affinity of nitrogen for other substances. As is well known, nitrogen, as we find it is inert and will not combine with other substances, not even with fluorine. By my process nitric acid and ammonia can be produced. These are the world's fertilizers. The barren parts of the earth can be reclaimed by them and made to produce with all the luxuriancy of past geological ages. There is much poetry in the idea that in this way the work of the sun on the earth can be made more effective."

Electricity for Motors.

Asked what he thought about the motors which would be most successful in the future for use in transportation Tesla said that the air motor had certain very beautiful features, but that his faith in electricity was very high and that he thought through it most of the work of the world would be accomplished.

In answer to a question as to the practical value of the things he had thus far accomplished Tesla claimed for the results of his investigations all the greater utility to the world because he had not patented them and attempted to derive personal gain from them. He threatened, however, to take steps to patent the next great invention he should make. "Wireless telegraphy," he said, "is something now that is free to all the world to experiment with. Nobody can hinder anyone from using a wireless instrument. I was the first man to announce the principle of the instruments now used by Marconi and others. I gave it to the world in a lecture in St. Louis in 1892. It may not be practical in your sense now, but it will be some time soon.

Alternating Currents His.

"Then there is the principle of alternating currents first announced by me and now universally applied in telegraphy. What could be more practical than that? At the lecture last night I was speaking of it and said that there was only one trouble with it from my point of view. 'What is that?' asked some one. 'That it won't work?' 'No,' I replied, 'that I didn't have it patented. It works for everybody.'"

In his view of what work is of the most value Tesla is consistent throughout. He believes thoroughly that work for the future is the work that counts. He believes that it is better to find out the general principles than to bother with the details of application. He threatens, however, to be in a position to make applications in many lines on an alarmingly big scale before many years have passed.

As to the methods of work which the inventor follows he said many things which were of interest. He boasted with a certain measure of pride that he had not for ten years performed an experiment which was a failure.

"Of course, there is sometimes a defective piece of machinery which has to be replaced, but when I make an experiment I know in advance always that it will succeed. Perhaps I have spent something like 99 per cent of my time thinking and 1 per cent experimenting. The experiment simply proves that there is no element in the situation which the thinking has overlooked. Then, too, there is a great pleasure in watching the actual accomplishment of what one has been able to predict by means of his science."

"Are you going to Colorado for a rest?" Mr. Tesla was asked.

"Rest? Oh, no," he answered. "I shall just keep on thinking on the same lines and will work as hard while there as if I were in New York."

Absorption in Study Complete.

Tesla told one or two stories tending to indicate his complete absorption in the investigation which he pursues. When speaking of the circumstances surrounding the invention of his sensitive rotating brush he said: "I had come back from attending the funeral of my mother, and was bowed down with grief, but I became absorbed in this study. After a time I forgot that my mother had died. I don't mean that I simply was so absorbed that I neglected to think of the fact, but I actually forgot it, and my mother was to me as one of the living. After a time I began to feel an overweening longing to visit her again. I felt that I could not resist it, and prepared to make the trip. Then something brought back to me the knowledge that she was dead, and I found that my work of investigation had actually stolen my memory on this point for a long time—months even."

Tesla says that his daily habits in New York City are such that he follows the same beaten track day after day. In all his years in that city he says that there have been only very few occasions when he walked on any other streets than those which lead from his lodgings to his laboratories, and he is perfectly satisfied with that limitation of his movements.

The Chicago Tribune May 15, 1899

TESLA TO "TALK WITH MARS."

Inventor Says He Has Discovered a Delicate Instrument That Will Communicate with the Planet.

Nicola Tesla, the electrical inventor, purposes to establish communication between the earth and the planet Mars. This is to be done by an instrument so sensitive that it will feel disturbances created anywhere on the globe. Mr. Tesla, last night at the Auditorium, said:

"One of the most wonderful things I have discovered is this instrument. With it I purpose to communicate with Mars."

"The coming century," said Mr. Tesla, elaborating on his lecture before the Commercial club Saturday night, "will be the era of the atmosphere. From the moment I discovered that the air under certain conditions was a better conductor than a brass rod I saw possibilities which made me grow fairly dizzy at their extent. The transmission of force and influence to any distance, the use of the sun's energy for all the needs of man, the possibility of controlling things with which there is no visible connection, these and an endless number of smaller achievements have become facts that in a short time will have their practical demonstrations.

"I am going on to perfect the ideas of transmission of energy which I have found in the new and measureless ocean of the atmosphere about us. The sun has furnished us eevrything, yet the energy it has to give is not used in the smallest part. The earth itself can be restored to the condition it was in when the ferns grew as large as trees. Distance, in the new method of transmission, amounts to little or nothing. The idea of wireless telegraphy which arouses such interest now because it is developed to a new basis is not wonderful at all compared to the principle of which it is one application."

Mr. Tesla declined to discuss the interviews on his work given by Arthur V. Abbott, Professor Jerome J. Green, and Professor Carhart after the talk before the Commercial club.

The Colorado Springs Evening Telegraph May 17, 1899

PRICE 5 CENTS. 50 CENTS PER MONTH

NIKOLA TESLA WILL "WIRE" TO FRANCE

The Wizard of Electricity Arrives in City at Noon and Will Carry on Extensive Experiments in Connection With Wireless Telegraphy and Upper Atmosphere.

Nikola Tesla, the wizard of electricity, arrived in the city at noon to-day.

At an altitude of over 14,000 feet he will harness the powers of the upper heavens and compel them to do his bidding. He will carry on extensive investigations in the realm of his chosen science—electricity, and with a view of solving the problem of sending a telegraphic message around the world, he will harness the Pegasus of the upper air to the chariot of science and bid it carry his messages whither he wills.

"I propose to send a message from Pike's Peak to Paris," said Mr. Tesla, in the corridor of the Alta Vista hotel this afternoon.

The Telegraph man asked him why he had chosen Colorado Springs as the basis of his operation. He replied: "I might as well tell you the truth. I have come here to carry on a series of exhaustive experiments in regard to wireless telegraphy. I will be here perhaps several months. I come here for work." He spoke quickly and softly and the cadence of a foreign tongue did not sound at all unpleasantly to one's ear.

"I see no reason why I should keep the thing a secret longer," he said. "I have been preparing for a long while to come here and carry on these experiments which have been so much to me. I am here to work out a system of transmission at a distance. I propose to propogate electrical disturbances without wires. I find it necessary to investigate the higher strata of air which I find so convenient to do in this altitude. I will also investigate electrical disturbances through the air and the earth.

"Are you going in the near future, to flash your message from Pike's Peak to Long's Peak or some other mountain of Colorado?" was asked.

HERE TO WORK.

"No," he replied, with quickness, almost approaching irritation. "I am here to work. It is not pleasure. I am very busy and life is short and there is a great deal to be done. I will attempt to design an apparatus to use in wireless telegraphy everywhere. Everything is crude yet. I hope to perfect it," he said, and he warmed up in his conversation, becoming very animated.

"Will you go Pike's Peak to-morrow?" was asked.

"I may go to-morrow or I may not. I am tired. I have been traveling, and may rest a few days. I have many experiments to make which will take several weeks. I must study the conditions of the upper strata of air and that will be my work. I have sent them already over distances and need not try that now. It is conditions I want to study. There are great laws which I want to discover and principles to command. When I have mastered this I will attempt my long distance signalling."

TWO ASSISTANTS.

"While here I shall make my headquarters at the Alta Vista hotel, where I have mu suite. Two of my assistants are coming and they will bring many instruments for the work. With these we will carry on our work and we will be very busy. There are conditions which I must study," he repeated, as if deeply impressed with some great thought or theory, which he was revolving in his brain. He lapsed into silence for a few seconds and then referred for a third time to the fact that he was here to study the upper strata of air.

He added: "In this high altitude there is much to be learned. The electrical conditions are more active than at the lower levels. Your air is charged with electricity. I hope for favorable results."

Tesla begged to be excused, saying he was wearied of the journey. He refused to state anything concerning his theories of signaling to Mars, or to some of the more distant planets except to reiterate his former statement that he was here for work in connection with wireless telegraphy.

WHO HE IS.

Nikola Tesla is a foreigner. His speech betrays it, yet he is a master of the English language, which he speaks remarkably well. His tones are soft and evenly modulated. He arrived from Denver at 1 o'clock to-day over the Gulf, and was met by his old time friend, Mr. Leonard Curtis, of the law firm of Hall, Preston & Babbitt. Mr. Curtis has known Mr. Tesla for the past fifteen years, and through Mr. Curtis' law firm in New York city then known as Kerr, Curtis and Page the business end of Mr. Tesla's affairs were conducted. All the great legal battles which Mr. Tesla has been compelled to wage in this country to protect his patent inventions have been carried on through Mr. Curtis' firm.

Mr. Tesla was Mr. Curtis' guest at lunch to-day at the El Paso club, and will be entertained by him for several days awaiting the arrival of Mr. Tesla's assistants.

As Tesla walked out of the Alta Vista to the El Paso club he took in the surroundings. As the breeze struck his cheek coming from the mountain, he glanced over to Pike's Peak and a look of preoccupation came into his eyes. The great electrician is wrapped up in his life work, and it apparently takes but little to throw him into a contemplative state from which he rouses himself with an effort. He, however, is a vigorous conversationalist and is very easy to approach. But when he once sets himself to his work he is difficult to see as his experiments require the closest watching and most intense application.

NIKOLA TESLA ON TOP OF PIKE'S PEAK

Wizard Who Works Without Wires Likely to Try Some Very Interesting Experiments.

Startled by the Amount of Latent Energy in the Atmosphere and Delighted Over the Prospects of Developing His Ideas.

NIKOLA TESLA, THE FAMOUS ELECTRICIAN.

Nikola Tesla, the noted electrician, has come to Colorado to make experiments in his chosen science. His tall and modest figure was to be seen last night in the corridor of the Brown Palace hotel, where the unassuming signature of "N. Tesla, New York," is registered to show that he is among the guests.

Mr. Tesla says that his objective point is Colorado Springs, from which he admits in an evasive manner that he may possibly take a trip to the summit of Pike's peak before he is done with his stay. What he intends to do on the top of the peak, however, the electrician would not say, nor would he admit that he attached more than ordinary importance to the possibility of making tests at that elevation. He carries with him some of his most delicate instruments, but this, he declared in his modest way, was always his habit and he thus evaded the assumption that he expected any important development from his visit to this state.

Impressions of the Air.

"Yes," said Mr. Tesla, "this is my first trip to this state, and I must say that I noticed the peculiar quality of the atmosphere as soon as I reached the altitude of the plains. It is very remarkable. You have so much electricity in the air. I felt it with my fingers the first thing, and when I handled the newspapers I noticed they clung to my hands. It shows that the atmosphere must be very dry, and you must all have good health here, do you not?"

The first impression of Mr. Tesla is his reserve, though there is not the least shyness about him. He is tall and rather straight and wears a slight dark moustache. There is a depth to his eyes that indicate a dreamy and more or less philosophic disposition. He is serious by rule, but occasionally he gives way to the sense of humor.

"You do not think I am here for pleasure, do you?" he asked, as if he felt hurt at a question. "I always work. Life is too short for anything else."

'Phoning to Mars.

The scientist denied a report that he had come to Colorado with the idea of carrying on investigations conected with his method of signaling to Mars and Venus. But he declared with a good deal of assurance that his investigations in this direction were correct. His instrument, he said, whereby the signals were given was of sufficient power to affect a receiving instrument on the sister planet with ten times the necessary force.

The details of this discovery had already been published.

"Cannot you tell the people of Denver why you have chosen Colorado as a place for your experiments and what you expect to derive from them in this atmosphere?" the electrician was asked.

"Of course you cannot expect me to expose my plans," Mr. Tesla replied in a serious voice. "That is not just. It is generally admitted that the air in this region is quite favorable to experiments of a certain class, and as I said I have been surprised at the quality of it, but I cannot say now what I am seeking. I intend to go to Colorado Springs soon and, since you ask, I may say that I shall probably visit Pike's peak. No, I have no intention of communicating with Mars from the top of that mountain. The instruments I have brought with me are used for the purpose of testing the electrical conditions of the atmosphere."

Always Working on It.

"Do you expect to do anything with the subject of wireless telegraphy?"

"My friend, I have been working on that subject for many years. I am always working on it."

"But, will you do any specific work upon it while you are here?"

"That is not a fair question. I cannot expose my plans."

The electrician spoke of some of his more practical inventions, and said he believed some of them were in use by electric light companies in this state. When asked if he would give forth the results of his work here in pamphlet form he said he rarely wrote books.

Nickola Tesla, the famous electrical inventor, as well known in these days as Edison for his remarkable electrical inventions, arrived in Denver last night. Just what his mission is none of the electricians of the city could tell yesterday, as there was no one in the city who had had any correspondence with him. J. W Stearns of the Mountain Electric company, said that he had known for several days that Mr. Tesla was coming to Denver, but he could only surmise what the object of his visit is.

The success of Marconi, the Italian inventor, in transmitting messages without wire, it is believed has aroused Tesla to an effort to outdo the Italian. Tesla claims that he made successful experiments in wireless telegraphy several years ago and that Marconi's work is but stealing his ideas. It is possible, however, that Marconi has simply been working on the same lines as Tesla and has arrived at a solution of the problem. It has often happened in electrical inventions that two or more men have reached the same result at almost the same time, neither knowing that the other was working on the same line. Notably was this the case some eight years ago when Tesla, Gaulard of France, and Gibbs of England perfected what has been known in this country as the Tesla transmitter for transmitting high potential energies to low and vice versa. Neither one of the men named knew that the other was working on the same line, and yet all three reached the same result at about the same time.

Tests in Rarified Air.

It is believed that Mr. Tesla's visit is for the purpose of making wireless experiments in the rarified air of Colorado. Mr. Tesla has already made experiments with the transmission of power as well as messages through air. These experiments have been made with his high tension generator. The central terminal of the generator is connected with elevated plates which require to be supported by kites or balloons. Here in Colorado the elevated terminals may be set on high mountains. Tesla thinks power can be transmitted at a height of about four miles. The air he believes will break at that height under the enormous potentials developed and become a good conductor. He hints, however, at dire results from the discharges of his coil when an electric motive force of a few million volts is discharged in the air. He says it may excite powerful affinities in the atmosphere, nitrogen causing it to combine readily with the oxygen and other elements, and the actions become so powerful as to ignite the atmosphere.

Specialties of the Inventor.

In practical use of electric power Tesla is best known for his methods of producing high frequencies and high potential currents in which an alternating generator sends currents through a primary, the secondary of which is in a circuit with a condenser. Practical application of this which every reader can understand is seen in the transmission of light into a house from an arc light current. The condenser or small transformer is placed outside the house and the current in transmission is reduced to the proper tension for an incandescent light circuit.

Tesla's high potential and high frequency pressure is seen in the recently constructed machines for the operation of mining plants, several of which are in operation in this state. In one plant of this kind set up by the Mountain Electric company a pressure of 60,000 volts is used. The arm for the switch board of this plant is over four feet long, the danger to human life in the use of this great power being such that a specially constructed switch board had to be made. Tesla in his experiments devised a series of transformers by which a pressure of 200,000 volts was attained.

Even as far back as 1894 Tesla declared to New York newspaper men that wireless telegraphy was a certainty of the near future, and if Marconi could successfully transmit a message across the English channel in the heavy and murky atmosphere of western Europe then much more successful should be experiments in the clear, rarified air of Colorado.

Tesla Lectures in Chicago.

Mr. Nikola Tesla was entertained by the Commercial Club, of Chicago, on May 13, and in the evening delivered an address before the club. Besides the members, many prominent scientists and educators attended the dinner in his honor, which was an elaborate affair. Mr. Tesla gave a number of interesting demonstrations, one of which was steering a boat from the shore, using a seven-foot model on a miniature lake, built in the banquet-hall for the occasion. His experiments did not begin until nearly midnight and lasted until a late hour.

OUR VISITORS.

Colorado Springs is to have its share of distinguished visitors this summer. Among those who are already expected with a considerable amount of certainty are Nikola Tesla, the electrician; Admiral Schley, and President Cleveland.

All these gentlemen will be welcomed, but we want a great many others, less distinguished perhaps but none the less desirable visitors to the foremost health and tourist resort of the Rocky mountain region. Hundreds of these people will come anyhow, for Colorado Springs is too well established in its reputation and acquaintances to lack for visitors, but there are many thousand others whom we might also have if proper means are taken to attract visitors and interest them in our climate, scenery and opportunities for profitable investments in mines and other branches of business.

NIKOLA TESLA AND HIS DISCOVERIES

The Great Electrician Will Communicate Without Wires

FROM NEW YORK CITY TO PARIS

Is In Colorado Springs for a Period of Several Weeks to Experiment In the Atmosphere of a High Altitude—Brought Forth the Principle Which Resulted in the Successful Subserving of Niagara to the Use of Man—Something of His Personal Appearance and Manner.

The one man who alone stands as a successful rival to Thomas A. Edison in the world of electrical research at the present day, Nikola Tesla, as the world knows him, is in Colorado Springs and will remain for several weeks. He is conducting experiments in which he desires to know the effect of the rarefied air of exceedingly high altitudes, with a view to the further perfection of his system of telegraphy without the agency of wires, the great object toward which all his ideas have been turning for some time, and for attainment of which the world of science and invention is looking to him today.

The Personality of Tesla.

Mr. Tesla is one of those men of great genius whom the world calls hard to fathom. It is generally supposed that he is averse to talking and very noncommital as to his purposes and aims. The Gazette reporter who called at the Alta Vista last evening, did not find him so. When the great master of the earth's greatest natural force is approached in an informal and interested manner he is a congenial and most interesting talker. He talks of his past work in a manner which is rather too technical for the comprehension of man of only ordinary education in the realm of electricity but is in no degree boastful.

The electrician spent part of the afternoon yesterday at the El Paso club and part of it at the Alta Vista hotel, which will be his headquarters while here. He is a man of more than ordinary height, probably measuring close to six feet. He is rather slender in build, has a pleasant face, with an eye that is quick and of keen perception, yet at times extremely meditative in expression. He has a black moustache. In dress he is not particularly striking, his whole make-up being that of a man who has a purpose of his own and who allows it to be uppermost in his thought during the greater part of the time.

Will Talk With Paris.

Tesla makes no secret of the fact that he is working at present to perfect his plan for wireless telegraphy. He stated in the interview last evening that he expected to remain in Colorado Springs for several week making experiments to ascertain the effect of the conditions peculiar to such a high altitude and that, having satisfied himself on the point, he will return to New York city, from which place he will apply his theories in an effort to communicate with the city of Paris without the use of wires. He thinks it will probably be a couple of months before he returns to the east to talk to France.

Has Harnessed Niagara.

Tesla has for some years been considered the coming man of the world interesting phenomena which have been the discoverer of some of the most interesting phenomena which has been brought out in the rapid onward march of progress in the great force. One of the greatest of his achievements was the proving of the basic principle which finally received its application in the great power plant which has brought the mighty Niagara into the service of man.

For years back men have known well that if they could successfully harness the water power of Niagara Falls they would have solved the problem of furnishing cheap, efficient and absolutely unlimited power for driving the machinery of practically the whole of New York state at one time. It was for Nikola Tesla, however, to come forth with that solution of the problem which all experts conceded to be practicable and which was eventually put into effect.

It was Tesla, although one or two others were working along the same line at the time, who put forth the practicability of polyphase currents which is the principle that makes Niagara a landmark in the journey through the field of electrical progress.

Discovered a Harmless Current.

It is well known that the current which gives the illumination in an ordinary electric light, although an alternating current, is a dangerous thing with which to come in contact and is practically the same force that is used for purposes of electrocution. Mr. Tesla several years ago made the interesting discovery that if the alternating currents could be made to alternate at a vastly increased speed over that which was then known, for instance at as great a frequency as 40,000 or 50,000 or 60,000 or even more times per minute, it would be harmless. He brought the discovery out publicly by making experiments on himself personally before an assembly of prominent electrical students and experimenters in London and the effect was extremely sensational.

It is also by the use of his greatly increased speed of aletrnation, that Mr. Tesla has succeeded in producing what is known as his electric light. It is for purposes of illumination and makes a far more beautiful glow than that of the ordinary light. At the World's Columbian Exposition in Chicago in '93 there was an exhibit of this light and it was considered one of the great features of the fair.

Mr. Tesla will remain in Colorado Springs for several weeks and upon finishing the desired experiments here, will return to his New York laboratories, where final arrangements for the application of his conclusions will be made.

The Denver Rocky Mountain News May 18, 1899

TESLA HERE FOR WORK

To Make Experiments in Electricity on Pike's Peak Summit.

Perfection in Wireless Telegraphy the Result That Is Hoped For.

Assistants On Way to Colorado Springs With Instruments—Resting After Tedious Trip From the East—Scientific Men Much Interested.

Special to The News.

COLORADO SPRINGS, Colo., May 17.—Nikola Tesla, the great electrician, is in this city. He arrived here at noon to-day and immediately engaged a suite of rooms at the Alta Vista hotel. In an interview Mr. Tesla stated that he would in all probability stay in this vicinity for some months, as he intended to make extensive experiments in this altitude, or rather, at the top of the peak. He said he had come here for work and not for pleasure nor for his health.

Two of his assistants are on their way here with instruments, and when they arrive the great electrician will ascend the historic peak and begin his experiments.

Mr. Tesla denied the report that he intended to attempt to send a message from Pike's Peak to Paris by means of wireless telegraphy. He admitted that he was here to perfect his system of wireless telegraphy and that when he had it perfected would try to send a message from New York to Paris by means of it. He said that he would not experiment from Pike's peak to Long's peak or to any of the other mountains in this state, saying that he was here for work and not pleasure.

As soon as it was learned that the great electrician was coming to this city great interest was taken in his visit, especially by the scientific men.

Mr. Tesla arrived in a very quiet way and reached the hotel without any display. At noon Mr. Leonard Curtis, who has known Mr. Tesla for the past fifteen years, took him to luncheon at the El Paso club and he will be Mr. Curtis' guest during the whole time that he is waiting for his assistants to come with instruments. The electrician was very much worn out by his trip from Chicago to this city and kept himself closely confined to his rooms most of the day, excusing himself to nearly all callers on the grounds of his weariness.

To-morrow, in all probability, he will receive the electricians of the college and others who are deeply interested in his work. It is not thought that Mr. Tesla will not ascend the peak until possibly the middle of next week.

The New York Journal And Advertiser May 18, 1899

MAYBE WE CAN TALK TO MARS.

TESLA AND SERVISS HOLD OUT HOPE.

COLORADO SPRINGS, Colo., May 17.—Nikola Tesla arrived in the city this afternoon from Chicago. He will carry on extensive investigations in wireless telegraphy on the top of Pike's Peak at an elevation of 14,000 feet.

"I am here to work out a system of transmission at a distance," he said. "I propose to propagate electrical disturbances without wires. I shall attempt to design an apparatus to use in wireless telegraphy everywhere. Everything is crude yet. I will go to the top of the Peak to-morrow. I have many experiments to make, which will take several months. The electrical conditions at high levels are more active than at lower. I hope to be able to send a message from New York to Paris."

Tesla purposes to establish communication between the earth and Mars. This is to be done by an instrument so sensitive that it will feel disturbances created anywhere on the globe.

Mr. Tesla said: "One of the most wonderful things I have discovered is this instrument. With it I purpose to communicate with Mars.

"The coming century," he continued, elaborating on his lecture before the Commercial Club, "will be the era of atmosphere. From the moment I discovered that air under certain conditions was a better conductor than a brass rod I saw possibilities which made me grow fairly dizzy at their extent.

"The transmission of force and influence to any distance; the use of the sun's energy for all the needs of man, the possibility of controlling things with which there is no visible connection—these and an endless number of smaller achievements have become facts that in a short time will have their practical demonstrations.

"I am going on to perfect the ideas of the transmission of energy which I have found in the new and measureless ocean of the atmosphere about us. The sun has furnished us everything, yet the energy it has to give is not used in the smallest part. The earth itself can be restored to the condition it was when the ferns grew as large as trees.

"Distance, in the new method of transmission, amounts to little or nothing. The idea of wireless telegraphy which arouses such interest now because it is developed to a new basis is not wonderful at all compared to the principle of which it is one application."

GARRETT P. SERVISS TELLS HOW MARS MAY BE SIGNALLED.

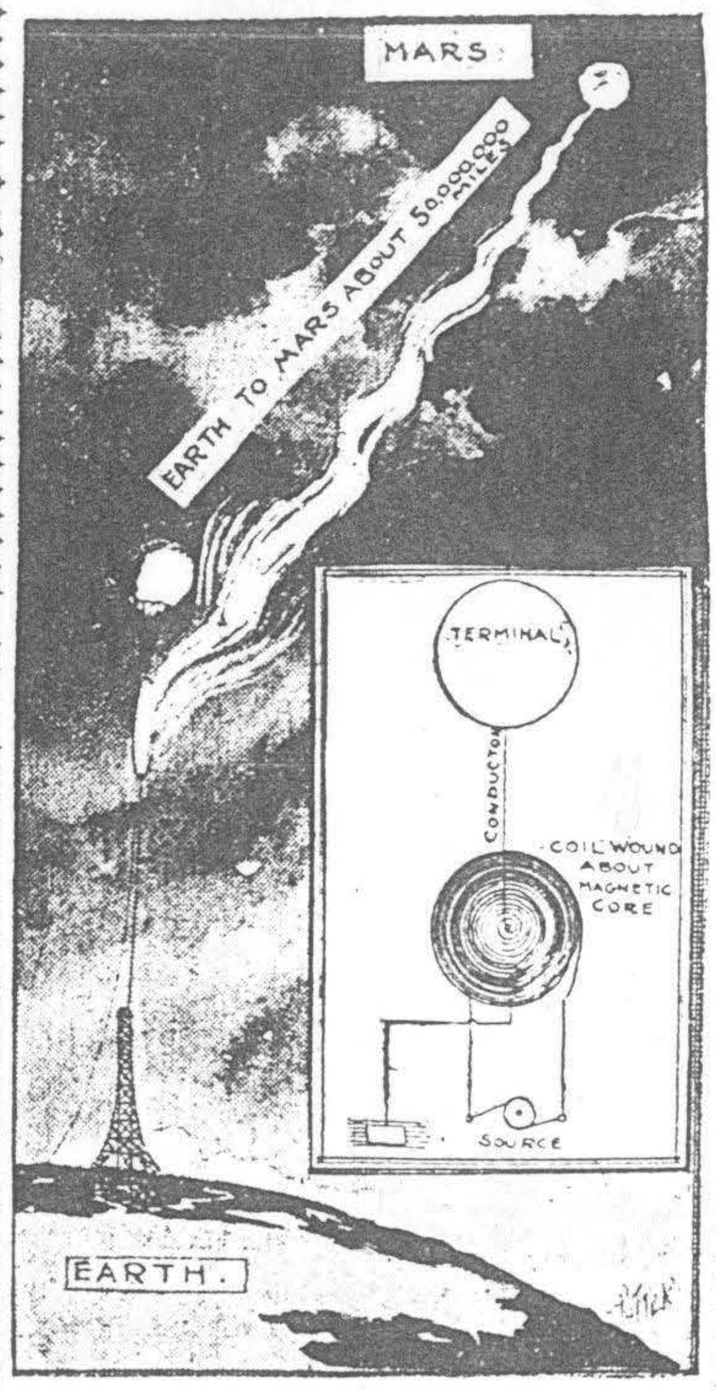
GARRETT P. SERVISS explained to a Journal reporter last night how, operating on Mr. Tesla's theory of wireless telegraphy, communication would be established with Mars or any other planet.

"Of course," Mr. Serviss said, "the explanation I give is based on the truth of Mr. Tesla's hypothesis that the possibilities of wireless telegraphy are infinite. This theory supposes that some intermedium conveys electrical waves, making a magnetic connection between the sun and earth. And the fact that there is such connection proves it.

"No doubt, when a great upheaval takes place on the sun (exactly what force causes these upheavals we don't know), an electrical impulse reaches the earth. Auroral displays and magnetic storms are the results of such impulses.

"The sun, under certain conditions, sends to the earth electrical waves which affect the electrical conditions of the atmosphere sufficiently to interfere with electrical and magnetic instruments.

"Now, suppose Mr. Tesla by some apparatus can generate on the earth an electrical impulse capable of being transferred to a certain planet, strong enough, I mean, just as the sun sends electrical impulses to the earth, then, of course, he could affect the electrical condition of the atmosphere of that planet. He could produce a series of interruptions and breaks on it, which, if there were any receiving instruments there, could be translated, as the Morse telegraph code is.



"Of course Mr. Tesla's scheme requires that Mars should have intelligent beings on it, who could respond to him, and as Mars is much older than the earth it is likely that this is the case.

"Assuming that this is so, let us suppose he could send an electrical impulse to Mars, which would produce some visible magnetic effect there. And let us suppose he could send this in the form of a code. Let him send three dots or dashes in rapid succession and after an interval another succession of dots and dashes. An intelligent person on Mars would see somebody was trying to talk with him. It might take years and years for him even to notice this, but, having once taken cognizance, he would set about putting the impressions into tangible shape.

"When the being on Mars decided that some one was trying to communicate with him he would set about translating the code. If Mr. Tesla should persist in following up the telegraphing, in time the receiver on Mars would undertake to find out where it came from. Having established this—not a difficult matter—he would send back, if he could, electrical impulses which would be in themselves a reply. If he could not send a return impulse at first he would reason out a plan, and in the end would find out how to do it. He would reply in a code of his own, just as Mr. Tesla would use his code. And as soon as an agrement of minds could be established it would be necessary only to invent a codal language which could be understood on both planets.

"This might take hundreds of years, but I may say the process would not be unlike the process followed when two men, thrown together and knowing nothing of each other's language, eventually invent a means of communication.

"If Mars's inhabitants are wholly incapable of understanding us, all efforts, of course, would be wasted. But, as I have said, the probability is that the mysterious planet's inhabitants are at least as far advanced as we are. It may be, indeed, that they have long understood these very principles we are just beginning to grasp, and have for years been trying to talk to us. It may be, indeed, that these initial efforts we are experimenting with are our first responses, unconscious that they are responses, to their attempts to communicate with us, and that, instead of making the first advances, we are being led on by them."

SIGNALLING FROM THE EARTH TO MARS BY ELECTRIC WAVES.

The New York Tribune May 19, 1899

TESLA'S COLORADO EXPERIMENTS.

MAY TRY TO TELEGRAPH WITHOUT WIRES FROM PIKE'S PEAK TO PARIS—TO STUDY UPPER-AIR STRATA IN COLORADO.

Colorado Springs, Col., May 18 (Special).—Nikola Tesla, the wizard of electricity, arrived here to-day, to spend three or four months in hard work from advantageous situations on mountain heights, ranging from 10,000 to 14,143 feet in altitude. He is in excellent health and spirits. Two assistants will arrive this week with a complete set of instruments for the investigations to be made.

"I have been preparing for a long time to visit Colorado Springs," said Mr. Tesla. "I have come to carry on a series of exhaustive experiments in wireless telegraphy. I find it necessary to investigate the higher strata of air, which I can well do in this altitude. I will also investigate electrical disturbances through the air and the earth. No, I shall not flash messages from Pike's Peak to Gray's Peak, or Long's, or any other. I am here to work. It is not a pleasure. I am exceedingly busy. Life is short, and there is a great deal to be done. I shall attempt to design an apparatus to be used everywhere in wireless telegraphy. Everything is crude yet. I hope to perfect it.

"I must study the conditions of the upper-air strata. There are great laws and principles which I want to study and command. When I master these I will attempt long-distance signalling.

"I may send a message from Pike's Peak to Paris. In these high altitudes there is much to be learned. The electrical conditions are more active than at the lower levels. This air is charged with electricity. I hope for favorable results."

An eighty-foot steel tower has been erected on the summit of Pike's Peak, which, while disclosing fifty thousand square miles of mountain and plain landscape to the tourists, secures Tesla 14,223 feet altitude. Sunset and moonlight trains, as well as two or more regular day trips over the cog road, make the summit easily accessible to the electrician under varying conditions, which otherwise he could not enjoy. Pike's Peak, while not the highest Colorado mountain, thus offers the most favorable conditions for electrical experiment.

Denver Rocky Mountain News May 20, 1899

TESLA READY FOR WORK

SECURES GROUND FOR AN EXPERIMENT STATION AT COLORADO SPRINGS.

Another Gift of $1,000 Made for a Room in Y. M. C. A. Building—Burglars Rob Warehouse at Noon—Hogeboome Sent to Reformatory.

Special to The News.

COLORADO SPRINGS, Colo., May 19.—Nikola Tesla, the electrician, keeps closely confined to his room and is practically unapproachable. It was learned to-day, however, that he has secured from W. S. Jackson the privilege of using a piece of high land in the rear of the State School for the Deaf and Blind east of the city, where he will construct a station for the purpose of carrying on his experiments. His assistants have not yet arrived with his instruments.

Facts

May 20, 1899

Nikola Tesla, the famous electrician, is now in the city, and will remain for some time. His reputation is world-wide, and he has accomplished wonderful feats in his chosen field of electricity, one of the greatest being the harnessing of Niagara. For some time past his special field of work has been in wireless telegraphy, and his visit here is for the purpose of making experiments in high altitudes. He is staying at the Alta Vista.

Tesla's Visit to Chicago.

Nikola Tesla's visit to Chicago and his published utterances have created a profound impression and have provoked no small amount of comment and criticism. Mr. Tesla came to this city as the guest of the Commercial Club of Chicago and delivered an address before that organization at the Auditorium, where a dinner was given in honor of the distinguished visitor.

The Commercial Club is a conservative organization, the membership being limited to 60 and composed of representatives of the leading commercial interests of the city. It was founded 32 years ago and has consistently adhered to the line of policy originally adopted. The dinner last Saturday evening at which Mr. Tesla was entertained was the 150th event of the kind in the history of the organization, and was therefore a red-letter day in the records of the society.

In addition to the members of the club there were several prominent men present by invitation, and a few electrical experts. Following is a list of those in attendance:

C. H. McCormick.
Nikola Tesla.
H. H. Kohlsaat.
H. G. Selfridge.
George B. Swift.
Edwin A. Potter.
Melville E. Stone.
W. G. Collins.
C. H. Wacker.
F. S. Winston.
George E. Adams.
T. C. Chamberlain.
A. V. Abbott.
Bruce Clark.
J. C. Whitney.
Benjamin Allen.
Samuel B. Downing.
Byron L. Smith.
N. B. Ream.
Robert T. Lincoln.
C. F. Kimball.
John J. Janes.
Granger Farwell.
Edward L. Brewster.
Marshall Field.
N. K. Fairbank.
A. S. Hibbard.
John M. Clark.
W. A. Fuller.
Victor F. Lawson.
S. J. McPherson.
Edward B. Ellicott.
Arthur D. Wheeler.
H. H Belfield.
Carl Keith.
E. G. Keith.
Henry Crew.
A. F. Seeberger.
A. A. Carpenter.
F. Carus.
Rev. Dr. Notman.
J C. Zeublin.

A. J. Earling.
Eugene S. Pike.

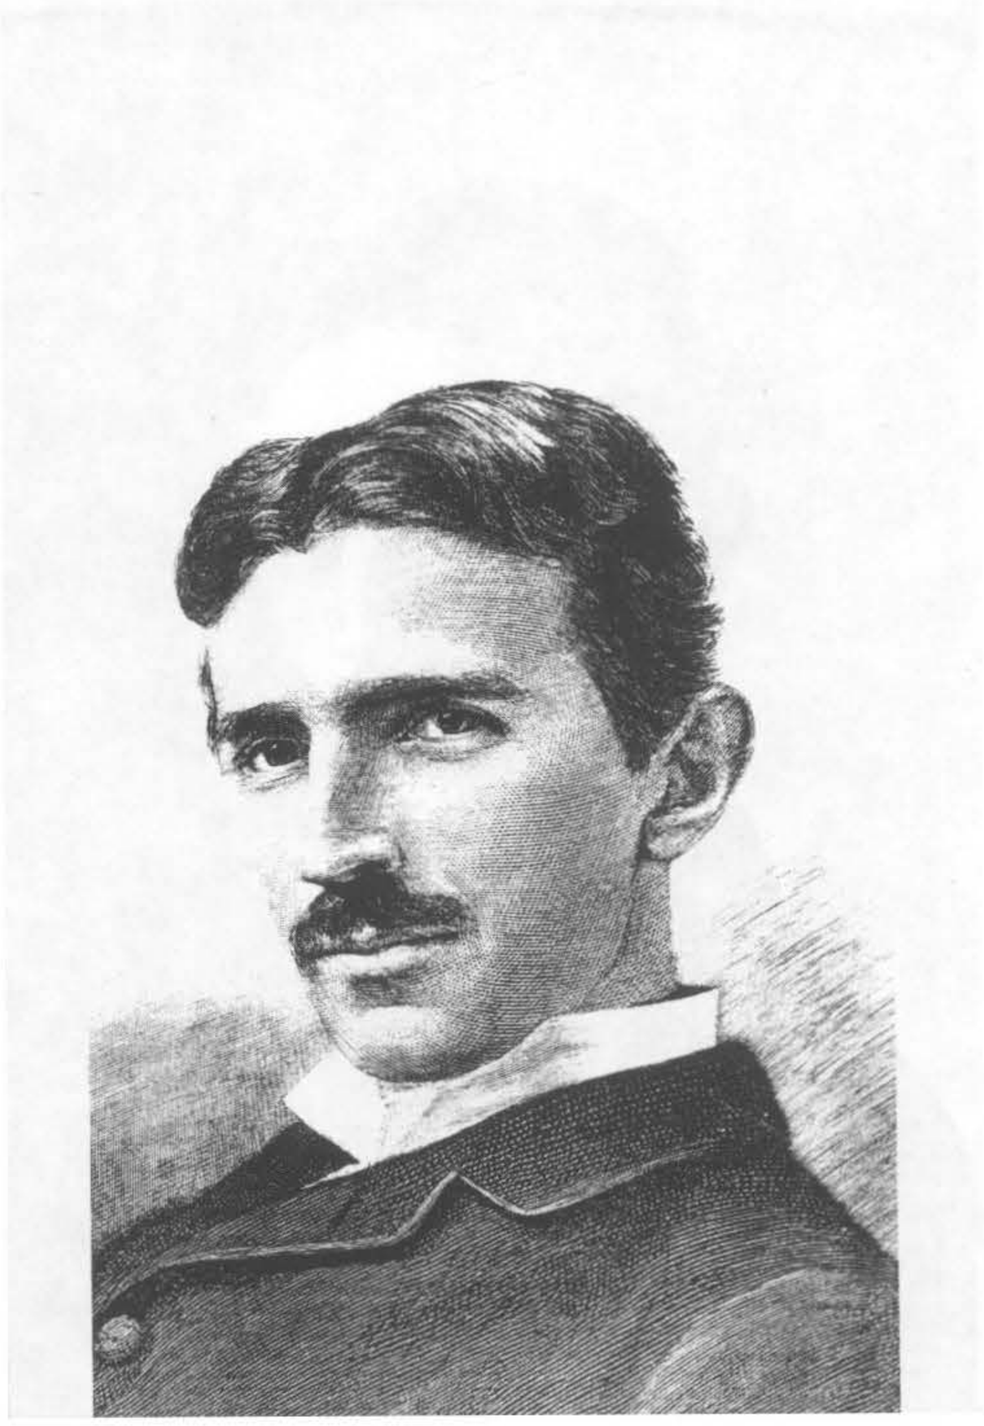
At the conclusion of the dinner President McCormick addressed the company, saying:

"We shall be much interested to hear from Mr. Tesla of the realm in which he dwells, which seems to us so incomprehensible, and if we become puzzled at the relative importance of 'amperes,' 'volts,' 'ohms,' 'induction' and 'polyphase currents,' Mr. Tesla must remember that, although we may know more about other things, we are still in the primary class in electricity.

"Since this great force of nature has been made subservient to the will of man, electrical progress has opened a wide field for both capital and labor. The Commercial Club will be interested in knowing that in this country alone the capital employed in the manufacture of electrical apparatus is $50,000,000; the telegraph interests represent $100,000,000; the telephone systems $110,000,000; while the investment in electric lighting is $247,000,000; this statement does not include the electrical equipment for elevated or surface railways."

Mr. McCormick paid a compliment to Mr. Tesla and the work he has performed in this field, and predicted even greater results than those already accomplished.

Mr. Tesla's speech was rather disjointed and disconnected, due partly to the nature of the address, which was punctuated with experiments and side remarks, and partly to his apparent difficulty in expressing his ideas. He took particular pains to make himself clearly understood, however, and the members of the club were highly entertained, although it was evident that they were also greatly mystified by the lecture and the experiments.



"There is no one," Mr. Tesla said, "who does not speculate about the questions of his existence, asking whence he comes, whither he is going and what in reality he is. Soul and matter and their relations have eternal interest for human beings. On the other side, there is always the desire to comprehend the marvelous manifestations of nature in all its phases. Let us talk of all of these."

With such a flexible subject it is not to be wondered that Mr. Tesla strayed from the paths of electrical science frequently during the evening and indulged in much speculation. He spoke for a time of the two terms, animate and inanimate, saying that he could distinguish between them in common language, but that for the scientist the case was not so simple, and he illustrated his meaning by an experiment with two disks, which he said were similarly constructed.

"One of these has life in it," he said, "and the other has not." Picking them up, he added: "Which is the active one I cannot tell, but we shall soon see." Then, while his assistant turned on a current, he tested each and determined which one was dead and which one was alive.

Then Tesla talked of the possibility of depriving a piece of iron of all its heat and energy until it had reached the absolute zero and the minimum of motion. "When the motion has ceased entirely," he said, "when the ultimate stage of condensation is reached, the matter would disappear. There may be going on in the infinite depths of space a process of appearance and disappearance of matter. We are working to test this by trying to reach the absolute zero. It may take centuries before we can reach this absolute zero, if ever, for the difficulties are very great."

Turning to another point, Tesla said: "It is necessary for us to assume a universal medium for the transmission of force. This results from the necessity of explaining the action of bodies at a distance. Energy is transmitted from the sun to the earth through some very attenuated medium. To show how such medium may be used under

NIKOLA TESLA.

certain conditions I may refer to a feat I once accomplished of converting a column of gas into a solid body by the application of electricity in a certain manner. The gas became rigid and vibrated like a steel wire. Scientific men have not noticed the importance of this as yet. Again, I have produced a solid body in the air on the end of a wire. I made a flame which consumed nothing and which showed signs of solidification, for it offered resistance to the passage of bodies through it."

He then told of a method he had invented for the production of ozone, which could be made in commercial quantities for sterilization and for purposes of sanitation. It was made by the process he followed in the production of this flame which had the power of resistance.

"The forces of the air may be utilized in a manner now that we have not learned to even contemplate. Nitric acid may be made from the components of the atmosphere."

"This nitric acid may be made to fill our reservoirs and then utilized to produce the energy we need and to transmit energy to almost unlimited distances."

His greatest invention, he said, was in utilizing the forces of the air.

"The air, which is an insulator," he said, "becomes a conductor by means of the millions of volts I am able to produce. It means the using of the air for all purposes and uses of men. Not only for the transmission of messages without wires, but for the transmission of power in any amount to any distance across the earth's surface."

Turning again to the distinction between living and dead objects, he said the two were not antithetic, but that the distinction was one in consciousness. He criticized the superficiality of the ordinary idea of life, saying that if our senses were keener we would entirely lose the feeling of individuality. He said that there were experiments which could prove scientifically the question of the continuation of individual existence, but that these experiments were impossible to perform. They would consist, he said, in demonstrating that any atom in the body behaved differently toward atoms in the same body than toward atoms on the outside. He next described the stages in the appearance of life on the globe, saying that all life was originally generated in the water. Ranging all the way from the lowest forms of animal life to the most complex, he pointed out the impossibility of showing the exact point at which life can be said to appear. Then he discussed the distinction between the phenomena of cause and effect and phenomena which mystify us. He gave his hearers something to see, flashing light in vacuum tubes without the aid of wires. Then he took a long tube in his hand and waved it like a flaming sword in the air before the machinery.

Describing many of the phenomena of his life and experience, he told how he had come to the conclusion that he was nothing else but an automaton in every act and sense. He explained how memory could be regarded as automatic, and told his hearers that some time he would write a philosophical treatise based on the facts he had observed.

"If I am an automaton," he said, "why should I not construct an automaton like unto me? What are the elements necessary? I am a heat-generating being, with powers of locomotion, with machinery to direct my movements, with a sensitive mechanism to provide data, and with a governing mind. My automaton must have all these qualities."

Mr. Tesla performed many of the experiments with which his name has been associated, showed his oscillator and explained its principle and operation, and then produced a model of a boat which he used to demonstrate in miniature his system of firing torpedoes and controlling the operation of machinery at a distance by means of electricity without connecting wires. In this connection Mr. Tesla recorded his claim to the invention of the system of "wireless telegraphy" with which Marconi's name is now generally associated.

At the conclusion of his address Mr. Tesla was the recipient of many compliments from members of the organization. Much curiosity was shown over the apparatus employed, especially that used in directing the boat and exploding torpedoes. Owing to the lateness of the hour it was impossible to examine it closely. The electricians who were present refrained from commenting upon the exhibition and the apparatus employed, as they did not have an opportunity to go into the matter thoroughly.

On Monday morning the Chicago Tribune printed an interview with Tesla, in which he was quoted as saying that he proposed to establish communication between the earth and the planet Mars by means of an instrument so sensitive that it will feel disturbances created anywhere on the globe. Mr. Tesla pronounced this instrument "one of the most wonderful things I have discovered."

"The coming century," said Mr. Tesla, elaborating on his lecture before the Commercial Club, "will be the era of the atmosphere. From the moment I discovered that the air under certain conditions was a better conductor than a brass rod, I saw possibilities which made me grow fairly dizzy at their extent. The transmission of force and influence to any distance, the use of the sun's energy for all the needs of man, the possibility of controlling things with which there is no visible connection—these and an endless number of smaller achievements have become facts that in a short time will have their practical demonstrations.

"I am going on to perfect the ideas of transmission of energy which I have found in the new and measureless ocean of the atmosphere about us. The sun has furnished us everything, yet the energy it has to give is not used in the smallest part. The earth itself can be restored to the condition it was in when the ferns grew as large as trees. Distance, in the new method of transmission, amounts to little or nothing. The idea of wireless telegraphy which arouses such interest now because it is developed to a new basis, is not wonderful at all, compared to the principle of which it is one application."

The Denver Rocky Mountain News May 21, 1899

TESLA HAS A RIVAL

Denver Man Has Invented Plan for Overcoming Induction.

Says He Can Telephone or Telegraph From Trains Moving Rapidly.

Astonishes All Experimenters by Saying That Oil Is a Good Conductor of Electricity and Other Inventors Make Mistake in This Respect.

Denver has a modern Tesla who out-Teslas even the wizard himself and who treats the impossible with a lightness that would easily confuse the experimenter at Colorado Springs. And Denver's Tesla has cropped out all because Tesla, the real, has achieved some favorable notoriety. There is one difference, however, between the two men. One has invented "things" and put them into use. The other promises to do so.

William Fremont Parker was at the Albany hotel last evening. He received his friends there, but his name didn't appear on the register. He replied when asked for his residence address that he was "in and out all the time."

About a year ago Mr. Parker experimented with telegraphing from moving trains. He stretched a few hundred feet of wire near a side track at Parker's station on the Colorado road and rigged up a little trolley to a car loaned by the company. The car was moved backward and forward and Mr. Parker sent a short message to Superintendent Dunaway. All this was by no means new, for several eastern roads have long been taking and receiving messages from moving trains, but not by the trolley method, however.

Mr. Parker last night told of the great benefit his invention would be to mankind. "Why, it will save the lives of 1,500 people each year who are killed in railroad wrecks." His idea is to put a bell in each of the coaches to alarm the passengers just before an accident happens.

But incidentally, Mr. Parker said he had discovered a method for overcoming induction from wires and making each line work without interference from others. This is entirely new, for electricians have for years considered this possible only by impracticable methods.

Then, Mr. Parker said his invention would permit the use of telephones from moving trains, but he would be compelled he said, to build insulated and sound proof rooms on the trains.

"How fast will your trolley work?" was asked.

"Oh, with a carriage well oiled and built of gutta percha and six-inch aluminum wheels with three-inch slots it will easily run 100 miles an hour and maintain a solid contact with the wires at exactly ten pounds pressure."

Then Mr. Parker said he had discovered that oil is a good conductor of electricity. That was entirely new, inasmuch as Tesla seems to have made the mistake of using oil to insulate his high potential converters in which currents of 40,000 volts are employed.

"Yes, it's a fact. Oil is a good conductor. Any street car man will tell you that," continued the inventor. He further explained that since his test he had done nothing with his inventions, but that he had written to the heads of several railroads and the Burlington had promised to permit him to build a hundred miles of wires along its road—under certain conditions.

THE arrival of Nikola Tesla at Colorado Springs, Col., on the 18th inst. has been announced in dispatches to the daily papers. Mr. Tesla has taken the trip to Colorado for the purpose, as he states, of carrying on "exhaustive experiments in wireless telegraphy." He has found it necessary, he says, to investigate the higher strata of air, and has chosen Pike's Peak as the location most suitable for his experiments. An eighty foot steel tower has been erected on the summit of the Peak, which, while disclosing fifty thousand square miles of mountain and plain landscape to the tourist, secures Tesla 14,223 feet altitude. Sunset and moonlight trains, as well as two or more regular day trips over the cog road, make the summit easily accessible to the electrician under varying conditions which otherwise he could not enjoy. Mr. Tesla is quoted in the dispatches as saying: "I must study the conditions of the upper-air strata. There are great laws and principles which I want to study and command. When I master these I will attempt long-distance signaling. I may send a message from Pike's Peak to Paris. In these high altitudes there is much to be learned. The electrical conditions are more active than at the lower levels. This air is charged with electricity. I hope for favorable results."

THE Chicago *Journal* has some facetious comments on Mr. Tesla's lecture before the Commercial Club at the Auditorium. It says: "Such a little thing as a quiet chat with inhabitants of the planet Mars will, if Tesla is sincere, be an everyday occurrence, and when you hang up the receiver of your Mars-communicating instrument, you may go out in the back yard and watch the weeds grow as large as poplars before you can say Jack Robinson. The vegetable kingdom will so abound with the two essential constituents, nitric acid and ammonia, that the luxuriant growth of the prehistoric eras will thrive again. Bananas will be as large as telegraph poles and peanuts like pumpkins, if Tesla can thus help the sun along."

Facts

May 27, 1899

The banquet given at the El Paso Club last Tuesday evening by Mr. Leonard E. Curtis was a memorable occasion. It was in honor of the distinguished electrician, Nikola Tesla, who is now in the city for a long visit. The eminent inventor is an old friend and client of Mr. Curtis and the host invited about twenty prominent men to meet him at dinner. After a few introductory remarks by the host, the noted guest talked entertainingly of his early life and ambition and of his latest successful achievements. The wonderful possibilities of wireless telegraphy and transmission of power were commented upon and his hearers were convinced that they were listening to one who is a thorough master of his subject and without a peer in his chosen field of investigation and invention. Governor Thomas, in a few well-chosen remarks, expressed his pleasure at being present and in meeting the guest of honor. Mr. Tesla is of a very retiring disposition and abhors notoriety of every kind. Like most men who have achieved greatness in any field of work, he is averse to talking of his successes. As his visit to Colorado Springs is for the purpose of special experiments in a high altitude, much interest is felt in his movements and operations.

In Society

Society has had a chance to do some lionizing;
And that the thing was carried out in style, is not surprising.

There's Tesla, who on Pike's high peak, will lure the lurid lightning
That with its jagged flash, forever common men is fright'ning.

There's Schley, the gallant admiral, a hero of the nation,
Who on the briny deep at Santiago won high station.

They're both aware that this fair town is famed for entertaining
Any guest who hereabouts, perchance, may be remaining.

Mr. Leonard E. Curtis entertained at dinner on Tuesday evening at the El Paso club in honor of Mr. Nikola Tesla, the eminent scientist. Twenty gentlemen were present, including Governor Thomas.

The Colorado Springs Evening Telegraph June 2, 1899

TESLA'S STATION IS READY

The building in which Nickola Tesla will conduct his experiments has been almost completed and will soon be ready for the use of that scientist and for the reception of such apparatus as he may deem necessary to the success of his trials. The building is a rough board structure and has been located on the north side of East Pike's Peak avenue, not far from the balcony which has been built on top a magnificent view of the grand old peak may be obtained. Nor have the plains been neglected. Mr. Tesla has, with the assistance of several friends here, endeavored to locate his experimental station as advantageously as possible in order to obtain the full benefit form mountain and plain, both of which the great electrician believes to be necessary to secure the best results from the tests that he will make within the next month or so.

The building is roughly boarded up, and is about 50 by 60 feet, with a lean-to in on the west, or front, in which are two windows and a big double door, the latter secured by a padlock. The structure is about 18 feet high, with a 12-foot roof, which slopes from near the center toward the four corners, thus enabling the carpenters to construct a fairly large platform or stand on the roof. The center of the building has not been covered, and Mr. Tesla will place his apparatus in the middle of the one big room, allowing it o extend upward out through the roof and above the platform which has been built around the aperture. That he intends to make use of the plains as well as the peak there is no doubt, as the magnificent view which can be obtained of both from the building clearly indicates Mr. Tesla's intention in this direction which he has also expressed to his friends. It is possible that he will make experiments in sending messages without wires from the top of Pike's Peak to the station and then endeavor to continue the system out across the plains. Or, if he intends to make experiments in the new and almost untried field of the transmission of motive electrical power without the aid of wires, the plains will also be of advantage to him in order to ascertain from how far a current, generated on the peak, can be utilized on the plains below, or vice versa. There is no doubt that Mr. Tesla intends to conduct experiments in one and perhaps both of these fields, and the whole civilized world will await with interest the result of his tests. If successful in either field it will completely revolutionize the present method of transmitting messages and motive power, and a new era in so far as the uses of electricity is concerned will have been ushered in with the new century.

Mr. Tesla is living very quietly at the Alta Vista hotel. He seldom sees any but his most intimate friends, and being naturally of a retiring disposition shirks as much as possible the many social calls that are made upon him. He has visited the new station and has expressed himself as being pleased with it, declaring that he believed the best results could be obtained there from the experiments that he desired to make. The building, which is exceedingly simple in design and architecture, was constructed after plans furnished by Mr. Tesla himself. After the building was completed Mr. Tesla feared that owing to a lack of sufficient foundation it might be wrecked by some high wind or gale, and at his suggestion the structure was securely braced on all sides except the west, and there is now hardly any likelihood of it blowing away, from which it may be inferred that Mr. Tesla is a great scientist, but a poor architect.

It is understood that the apparatus will be placed in position as soon as it arrives from the east, and that Mr. Tesla will then devote himself to daily work in the station.

A SPRINGS YOUTH MAY BE A TESLA

Is Transmitting Telegraphic Messages Without Wires

STATIONS ARE 60 FEET APART

Burnell Ford, a Clerk Employed by Mr. W. N. Burgess, is Working With Some Considerable Success at Wireless Telegraphy — Began With His Stations Only a Foot Apart — Almost All His Work is Done at Night and With Equipment Which He Has Made Himself—Will Now Erect a Pole on His House and Go Further.

Nikola Tesla, the world famed electrical discoverer and experimenter is not the only man in Colorado Springs who is exerting himself to perfect a system of wireless telegraphy. The world looks to Tesla and it is to be expected that either he or some other experimenter of long years of experience will be the first to proclaim to the world his success in what is the great problem in electrical research at the present day.

Notwithstanding this fact there is a young man in Colorado Springs who is laboring along the same line or for the same end and who has attained at least some degrees of success. He is Mr. B. R. Ford, a young man of about 22 or 23 years of age, who has been for some time employed in the store of W. N. Burgess.

What He Has Accomplished.

Mr. Ford resides at 712 East Huerfano street, and it is there that his efforts are being put forth and that he has achieved his present success. He has a laboratory which he has himself fitted up and although it does not contain the vast amount of equipment that is available for the use of experimenters who have unnumbered thousands at their disposal, it has been sufficient for him to have made progress which is, to say the least, encouraging.

Mr. Ford has been at work for several months. At first he applied his theories with his stations only one or two feet apart. Finding himself successful he moved them apart to a distance of eight or ten feet and was soon transmitting messages successfully from one to the other. He has continued in his efforts until now he is successfully transmitting messages from a station in his laboratory, through the walls of the building, to another station 60 feet distant.

To Direct the Rays.

As is the case with all experts who are endeavoring to perfect a system of wireless telegraphy, Mr. Ford is directing his study and effort toward securing control of the direction of the rays of electricity. In his experiments he is using an Edison battery to excite his coils and an ordinary salammoniac battery on his condenser. While not making any big claims as to what he is going to do or pretending that his present success is anything that should startle the world, Mr. Ford is extremely enthusiastic in his work and belives that his progress toward the goal will continue.

He will immediately erect on the roof of his house a pole about 30 feet in height and from a station on that pole will endeavor to communicate with different points.

His Instrument Clicked.

The young Colorado Springs experimenter has brought about his present success as a result of hard and careful work at such times as he could devote to it. Being engaged as he is during the entire day the most of his work must be done at night and it has been so.

He states that a few days ago he was sitting in his laboratory watching the instrument by his side when all at once he heard it begin to tick. The signals came clear and distinct but were too rapid for Mr. Ford to catch and he does not know what was the story told by his instrument. He staid beside it, however, and heard it click more or less for two hours and a half. He has not yet discovered what was the source of the rays which operated his instrument. Were it not for the failure to have heard it at other times he would believe that the source was in the Santa Fe depot which is near his home.

Will Continue the Work.

Mr. Ford expects to continue the work along the lines of his present activity. He is compelled to make a considerable portion of his equipment and to gather up different parts anywhere he can but the result of what he has thus far done would indicate that he knows how to use what he gets. Doubtless his work will be watched with great interest by all Colorado Springs.

Nikola Tesla.—We notice in the *Western Electrician* an account of a lecture given by Nikola Tesla before the Commercial College, Chicago. Our contemporary remarks that Mr. Tesla's speech was rather disjointed, partly owing to the nature of his address, which was punctuated with expressions and side remarks, and partly through his apparent difficulty in expressing his ideas. "There is no one," Mr. Tesla said, "who does not speculate about the questions of his existence, asking whence he comes, whither he is going, and what in reality he is. Soul and matter and their relatiors have eternal interest for human beings. On the other side, there is always the desire to comprehend the marvellous manifestations of nature in all its phases. Let us talk of all these." We quite agree with our contemporary, if the following remarks are correctly reported. For instance, we are told that Mr. Tesla talked of the possibility of depriving a piece of iron of all its heat and energy until it had reached the absolute zero and the minimum of motion. "When the motion has ceased entirely," he said, "when the ultimate stage of condensation is reached, the matter would disappear. There may be going on in the infinite depths of space a process of appearance and disappearance of matter. We are working to test this by trying to reach the absolute zero. It may take centuries before we can reach this absolute zero, if ever, for the difficulties are very great." Again, Mr. Tesla referred to an experiment in which he said he converted a column of gas into a solid body by the application of electricity in a certain manner. The gas became rigid and vibrated like a steel wire. We can quite conceive that the lecture was exceedingly difficult to follow, but we think that Mr. Nikola Tesla would enhance his reputation more by delivering a lecture which was clear and comprehensive rather than by delivering himself to utterances which were evidently intended to mystify those to whom he was speaking.

BURNELL FORD AND WIRELESS TELEGRAPHY

Colorado Springs' Young Experimenter and His System

DESCRIPTION OF HIS LABORATORY

Has It Equipped For Experiments in Electricity and Chemistry---Lighted With Acetylene Gas — Has Erected a Forty Foot Pole on the Roof and Will Experiment at Increased Distance.

As stated in the Gazette a few weeks ago, there is in Colorado Springs a young man who is making some remarkable strides toward success in wireless telegraphy. Since that announcement of his achievements it has been the privilege of the Gazette to make further investigation of his work and to witness the results which he is able to bring about.

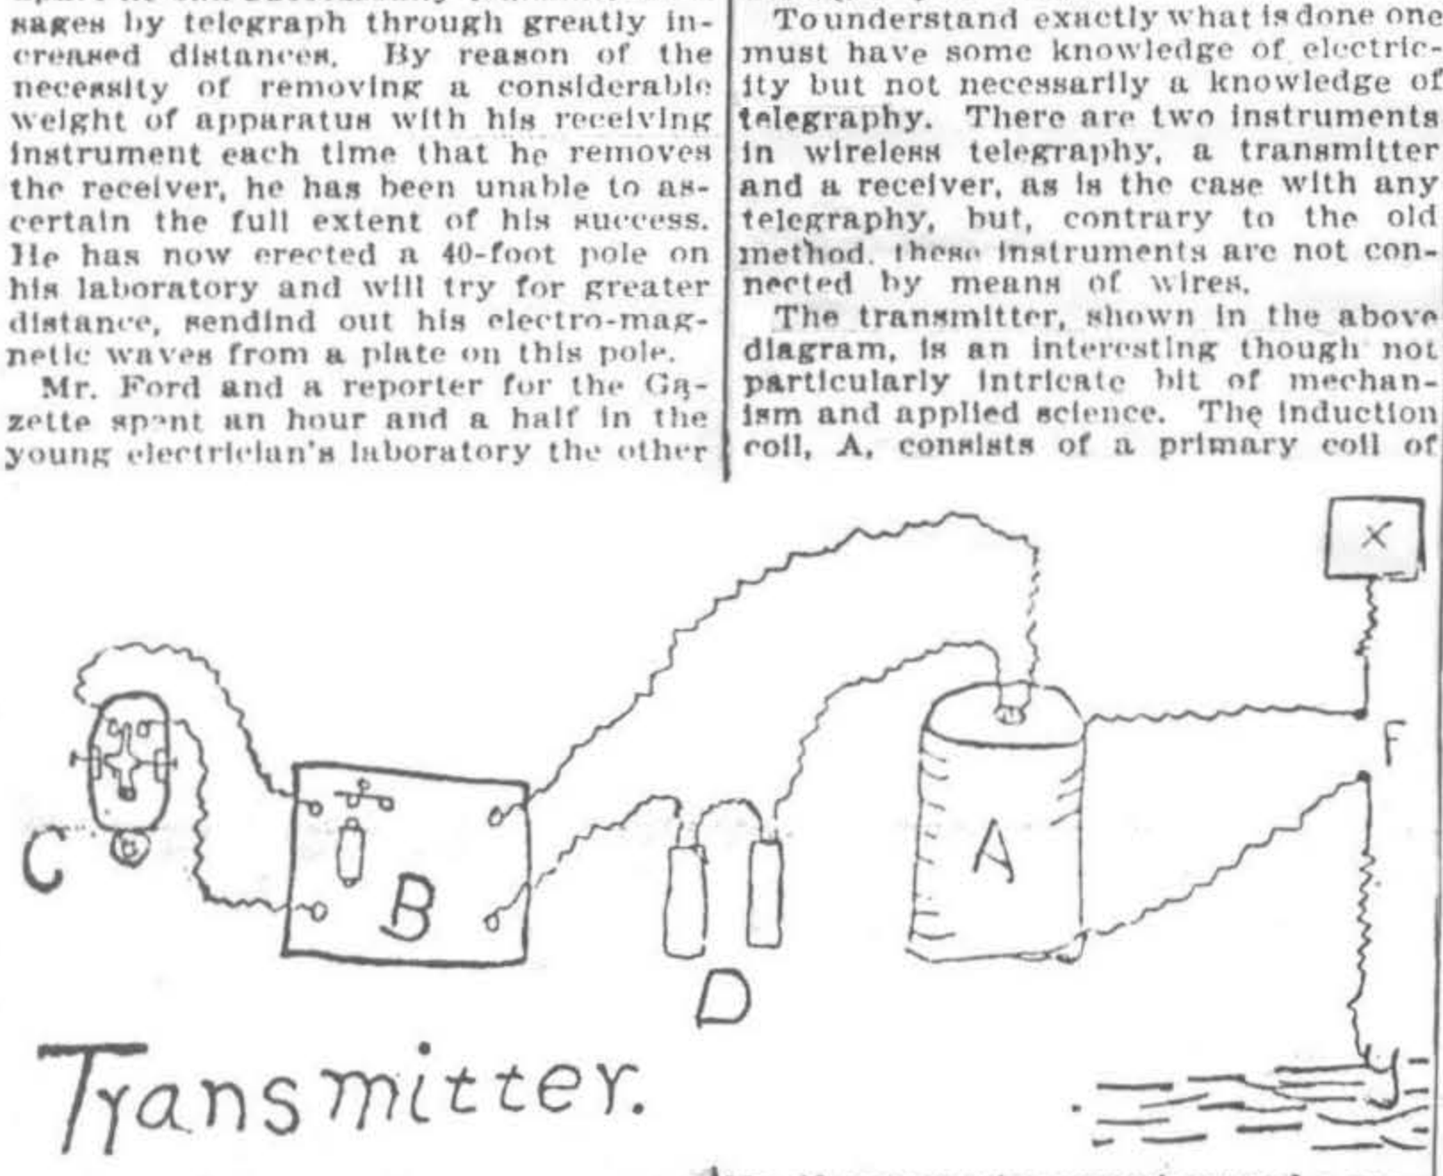
Ford's Success to Date.

Since that time, also, the young man in question, Mr. Burnell Russell Ford, of 712 East Huerfano street, has been continuing his experiments and has attained even more gratifying results than were then announced. He is now transmitting messages a distance of 75 feet and through the walls of a brick house and is perfectly confident that when he can get his stations farther apart he can successfully transmit messages by telegraph through greatly increased distances. By reason of the necessity of removing a considerable weight of apparatus with his receiving instrument each time that he removes the receiver, he has been unable to ascertain the full extent of his success. He has now erected a 40-foot pole on his laboratory and will try for greater distance, sendind out his electro-magnetic waves from a plate on this pole.

Mr. Ford and a reporter for the Gazette spent an hour and a half in the young electrician's laboratory the other evening and the experiments were tried and the reporter was astonished beyond expression. There was something more than admiration in the thrill which passed through him as he watched the youthful experimenter operate a little key similar to that which is used in transmitting any telegraph message, saw a little spark fly from one wire to another each time the key was pressed and heard a receiving instrument stationed at the extreme far end of the room, entirely disconnected from the transmitter, respond with its sharp, quick click as regularly as the sender pressed his key.

Concerning the Laboratory.

The scene of the operations of this young man is a very interesting place. He has built in the back of his yard a small house, probably 10 by 10 feet in size. In this he has a corner for photography; on the wall there is a small library of electrical works including the leading scientific papers and many up-to-date books; one corner is devoted to chemistry, and is well equipped for the study of that science. On one wall there is a big plate which comes into use in many of his electrical experiments; a long bench for general utility is upon one side of the room, and wires and batteries and parts of different instruments may been seen on any part of the walls or the shelves. In one corner there are four Edison-Lalande batteries and upon a small stand made for the purpose there is an induction coil about 10 inches in height and 10 in diameter. This coil was made by Mr. Ford and took all his spare time for about three months.



One of the extremely novel features of the laboratory is its light. Mr. Ford has succeeded in making Acetylene gas, generating it with an automatic generator of his own manufacture.

Detail of the System.

While there are a hundred things of interest in this little "den," the greatest interest centers in the subject which takes one to the place—the transmission of telegraphic messages without the agency of wires.

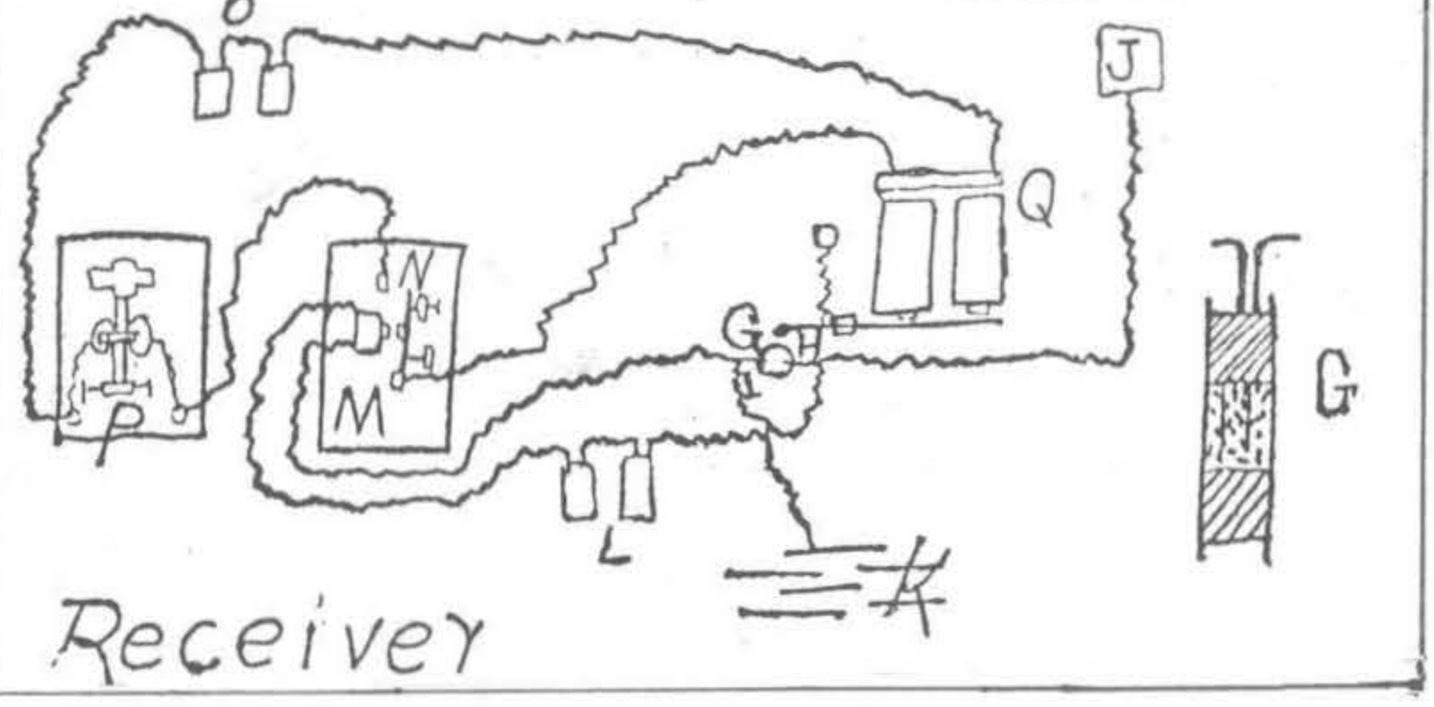
To understand exactly what is done one must have some knowledge of electricity but not necessarily a knowledge of telegraphy. There are two instruments in wireless telegraphy, a transmitter and a receiver, as is the case with any telegraphy, but, contrary to the old method, these instruments are not connected by means of wires.

The transmitter, shown in the above diagram, is an interesting though not particularly intricate bit of mechanism and applied science. The induction coil, A, consists of a primary coil of No. 18 copper wire wound around a core of soft iron pipes. Around this is wound several miles of No. 36 silk-covered copper wires, which form the secondary. The secondary is insulated from the primary by a thick wax tube. B is an automatic circuit breaker with a condenser in the base. C is a common telegraph key. D represents four Edison Lalande batteries.

Transmitter.

The sender of a message, by pressing the key at C, causes a stream of sparks to pass in rapid succession between the two points at F, these sparks sending out electro-magnetic waves through the air in all directions. In sending a message all that is necessary is for the operator to use a key at C, just as he would in sending an ordinary telegram. A spark at the points, F, responds to every touch of the key at C. One terminal of the secondary connects with the plate, X, which is hanging on the pole above the roof of the laboratory. The other terminal is connected with the ground, Y.

The coherer, which is the detecter of the electro-magnetic waves, and really the secret of the system, is a discovery of Marconi's to a great extent. It is really, however, a comparatively simple bit of apparatus. Mr. Ford's coherer is a small glass tube filled with a mixture of iron and brass filings, the iron having been exposed for some days to the air. Running down into the filings are the two copper wires, H and I, H being connected to a metal plate, J, and also being connected to one pole of the battery, L. The wire that then connects I with the ground is connected through the relay, M, and back to the battery, L.



When no electro-magnetic waves are passing through the air the resistance of the filings in the coherer, G, is so great that the battery current cannot pass. But immediately upon the pressing of the key, C, of the transmitter, a spark passes between the points at F and the electro-magnetic waves, being sent out through the air, arrange the filings in the coherer, G, in such a position that the resistance is considerably reduced and sufficient current from the battery, L, passes through to work the relay, M, which is in the same circuit. The relay, in turn, closes the circuit at N and a current flows from the battery, O, through the ordinary telegraph sounder, P, through the contact point which was closed by the relay, thence through an electro-magnet, Q, which causes a small brass ball to tap the coherer, G, thus disarranging the iron and brass filings inside and breaking the relay circuit. The receiver is then ready for another electro-magnetic wave from the transmitter. At the instant the key at the transmitter is pressed the coherer and relay act, the sounder clicks, the coherer receives a little tap and the receiver is ready for another pressure on the key. Thus messages may be sent by the same code used in ordinary telegraphic work, but somewhat more slowly.

Some Other Experiments.

While the wireless telegraphy is the most important experiment at which Mr. Ford is working, as, in fact, is the case with electricians who are known far more widely, it is not the only line along which he has been thinking. He has found that an ordinary incandescent light bulb, when held in proximity to but entirely separated from almost any part of the transmitter, will show a beautiful effulgence. It is rendered much more beautiful and interesting if the ends of the bulb be wrapped in common tinfoil. A stranke fact is that no two bulbs will give the same kind of a light. One will show a pale, greenish, misty light; another shows figures and squirmers which remind the beholder of Eugene Field's "Seein' Things at Night;" another shows perfectly-formed stars and other shapes, and other queer fancies of just as diverse nature can be seen.

The young man is applying in his experiments much that he has learned in his studies under the International Correspondence school of Scranton, Pa. All his work must be done at night and at spare moments, as he is in the employ of W. N. Burgess and is busy during the day.

"That is one of the things I do not understand," said Mr. Ford, as he put another incandescent light globe up to the plate and brought out some new pictures, "but it's the kind of thing I meet with all the time. I have a few ideas that I am working on that I hope may prove interesting, but I do not care to tell much about them, as they may not amount to anything. I have put up this 40-foot pole to get bigger results with the telegraph. The greater the distance through which the message is to travel the higher the plate needs to be. At least that seems to me to be the case, but I don't know why it is. The ground may short circuit it if it is too low, or there may be some other force that I do not know of. At any rate, it is a very fascinating study."

Receiver

In Society

Nikola Tesla was visited by Herr Baumgart, of Frankfort-on-the-Main, Germany. He is an electrician of considerable renown.

The Colorado Springs Evening Telegraph June 21, 1899

TESLA IN HIS WORK ROOM

All the apparatus necessary to successfully conduct his experiments, has been received by Nickoln Tesla, and his experimental station near the Printers' Home is rapidly taking on an air of activity. The rough frame structure is filled with dynamos, electric wires, switches, generators, motors, and almost every conceivable invention known to electricians, and through this mass of intricate and dangerous mechanism Mr. Tesla walks as fearlessly as if on the streets of the city. He knows, perhaps, better than anyone else, just how deadly his appliances are, but he works with them without the least fear, though the least bit of carelessness on his part would result in instant and awful death.

He has several assistants, all of whom handle the various electrical appliances with great caution, but Mr. Tesla seems to know the exact condition of every wire and every dynamo in the house. He has no fear of grasping a "live" wire, and handles the powerful machines which are to generate the currents of electricity that are to be transmitted to Pike's Peak in the form of intelligible messages, without scarcely a thought as to the great danger.

Mr Tesla's experiments have not progressed very far, as yet, and though he is averse to talking for publication, it is known that he has done nothing that would warrant him in asserting that wireless telegraphy, as he conceives it, can be devoted to practical use. Mr. Tesla has two little rooms on each side of the main work-room which he has fitted up in a plain manner, and in these he plans out the details of his work and his experiments. The main apparatus is ,of course, in the center of the big building, and is very complicated. It was put in place by the assistants upder the personal direction of Tesla, and while it is in good order, nothing has been accomplished of enough importance to be given to the public.

Within the next week, however, it is hoped that something tangible will be accomplished, and that Colorado, and Colorado Springs in particular, will again be the center of all eyes in the civilized world, in having been the place where Tesla successfully demonstrated that wireless telegraphy was an assured fact and that electric motive power can be transmitted for a considerable distance without the aid of wires.

NIKOLA TESLA EXPERIMENTS IN THE MOUNTAINS.

ABOUT a quarter of a century past, books of "Familiar Science" were popular in certain of our institutions of learning, together with "Chronology," taught as a separate branch, disassociated from events,—and Magnall's Questions. The exhaustive study of "Ancient Geography" was also commended, and " a page of dictionary" was the invariable spelling lesson. Walker was the standard authority, and in his pages the present writer learned to spell music, "musick," and sundry extra "u's" and doubled consonants, which are fine old historical English, Isaac Pitman to the contrary notwithstanding. It was the special privilege of the book of "Familiar Science" to hurl disconnected facts at the scholar's head—to pelt him with the arbitrary processes of nature—"Why does dew fall?" paraded arm in arm with "Why does a cat's fur emit sparks when you stroke her in the dark?"

But the chief glory of the "Book of Familiar Science" was a full-page wood-cut of placid Benjamin Franklin, in broad-brim and gaiters, flying his scientific kite, and bringing lightning down from the skies by the aid of a large door key. The experiment marked the beginning of electrical science in America. "The knowledge of this world passeth away."
away."

In the first years of 1800, Lieutenant Pike camped at the foot of his great "Mexican mountain"—that "far blue cloud" which allured him over many a mile of wilderness march, and from his reports of discovery of Pike's Peak and exploration at the head-waters of the Platte and Arkansas, began the exodus from the Missouri river—first over the Santa Fe trail direct—and then gradually diverted to the north, where "Pike's Peak or Bust!" became the motto of the "'59er."

The years to be dated 1800 are fast drawing to a close, and in spanning them in thought, with all their stirring happenings and marvellous achievements, not a hundred years later than Zebulon Pike, we find another discoverer camped at the foot of Pike's Peak, armed with a more mighty key to electrical science than that of Poor Richard.

Nikola Tesla, the Servian scientist, whose electrical discoveries are not of one nation, but the pride of the world, has taken up his abode in Colorado Springs, where he will remain for some time conducting experiments in the medium of light air, and perpetual sunshine.

On East Pike's Peak avenue, with limitless plains stretching to the eastward, and a panorama of mighty mountains sweeping away north and south, to the west—Tesla has caused to be constructed a station for scientific research. It is a building, which, when complete, will cover an area of from 50 to 60 feet, with an extension with two windows and a large door. The structure is about 18 feet high, and crowned with a large platform. The center of the building remains unroofed to permit the scientific apparatus to project above, and to be inspected and regulated from the surrounding balcony. The structure has been built according to Mr. Tesla's own plans, and in telegraphing without wires from plain to mountain, or from mountain to plain, it would occupy an equally central situation.

It is said that Mr. Tesla's experiments will take this direction, though he is, naturally, reticent upon these points, until he is assured, by the success of his experiments, that the results are prepared to meet the demands of the scientific world.

With Tesla's wireless telegraph oscillator, he affirms he could talk to the inhabitants of the planet Mars, and will talk to the people of this earth, at any distance away, without the assistance of wires. Into the great oscillator Tesla will turn an ordinary current of electricity. The os-

cillator instantly transforms this electric current, by a series of coils, into an electro-motive force, vibrating at the rate of 2,000,000 to 4,000,000 times a second. This starts electric waves through the air and earth, which vibrate almost as fast as the waves that produce light, and travel with the same speed. These waves, like X-rays, pass through any dense substances, and, according to Tesla, there is nothing to prevent the transmission of messages by their aid directly through the earth. Tesla's plan for cabling across the Atlantic is to erect two terminal stations, one in London and one in New York, with the oscillators placed at the top of high towers, communicating thence with great disks suspended in captive balloons floating 5,000 feet above the earth to catch the strata of rarefied air through which electrical waves travel most easily. A message could be flashed instantly by these lightning rays from the oscillator to the disk in the balloon, and across the thousands of miles of intervening space to the second disk. Cable tolls would be reduced to a minimum ,and messages flashed around the world at little more than letter postage rates. Mr. Tesla says he is ready to put his wireless system into operation as soon as the practical details can be arranged.

In inter-planetary communication, however, it would be necessary to have a receiver upon the objective star, and it is also a pre-requisite that the inhabitant of Venus or Mars (if there he be) should—unlike some who wear the uniform in this sublunary sphere—"know enough to take a message."

The oscillator, charged, seems like a vivid sphere, fairly radiating light and glorious possibilities. Who that has looked into the soft green depths of light, in the heart of which lies hidden the X-ray (to which matter is no longer opaque and impenetrable), has not felt that under the touch of electric light and force, power is limitless and the future boundless?

In Bulwer-Lytton's novel of "The Coming Race," the heroine was a "perfect woman, nobly planned," on a superhuman scale. She and her sisters took the initiative in all good and wise achievement, while the men of the coming race somewhat lagged in the rear. By means of the "vril" staff, power was transmitted or arrested, in an incredible degree. The labor of the coming race was performed by automata, vivified and directed by the action of "vril," according to the mind of him who held the staff. In the spirit of the woman who wished that "posterity was here —right now," the employer of the present longs for the "vril" staff. There are so many, who, upon attempt of direction by the guiding mind, do the thing that is not wanted, in just the way that is not desirable or right.

Colorado, with her enfranchised women, opens a future for the sisterhood of the coming race. Tesla, in an interview with a representative of the Denver Republican, indicates that the day of "vril power" is not far distant.

"I would," said Tesla, "light whole cities and give to mere machines all the motions of intelligence. I have given demonstrations of this discovery of mine before bodies of men of science many times, but they have found it difficult to believe me. I gave a demonstration of one experiment, which I think is the most beautiful I have ever tried. I think if I live a long life and work all the time I shall never have a more beautiful experiment than that. I had a boat without crew or captain, which I controlled merely by the force of my intelligence. I would will 'turn,' and it would turn, 'go to the right,' and it would go to the right, 'to the left,' it would go to the left. The beautiful thing about it was that it seemed to be instinct with life, and, as a dog obeys the commands of his master, so this machine obeyed mind. And yet, it was governed simply by electrical waves striking upon a receiver. And so with any machine.

"Why, I could make an automaton in the shape of a man that could walk, move, perform all the motions of a man, except wherein the fact of its not being an organic being would make a difference. All this theory is developed from my idea that the actions of all animate beings are governed by impressions of outside objects received upon the eye.

"My idea is that people are simply automata, governed by the transmission of circumstances surrounding them upon the eye. This," said Nikola Tesla, solemnly, and with the greatest simplicity, "is the greatest idea of the age. The relations of nations will be affected by it. It will revolutionize thought. It may take years, but it will gradually come about. Men of science find it difficult to accept this idea. They cannot comprehend it. It is stupendous, and yet it is very simple."

Colorado may be the theatre of the first exhibition of "vril."

Mr. Tesla announces that he is at Colorado Springs, simply collecting experimental data. His instruments will shortly be mounted, and scientific work will begin. He has made similar experiments at different atmospheric levels, and the work here will be comparative.

Nikola Tesla is from the mountains of Servia, and his native tongue is Montenegrin. To those familiar with foreign types, he suggests the Pole —the grave and gentle temperament illumined by the flash of fire. He is very tall and slight, with thin and delicate features, black hair and mustache, and clear gray eyes. He speaks of himself and his work with simple modesty and reticence, in perfect English, with a slight foreign accent.

Mr. Leonard E. Curtis, a well-known member of the bar, who has been Tesla's legal adviser, gave a banquet to the famous electrician at the El Paso Club, where twenty gentlemen of Colorado Springs were invited to meet him, including Governor Thomas, of Colorado. Tesla was in his happiest vein and spoke of his life and work. When first he heard of the great Niagara of the western hemisphere, he was impressed with its power—mighty, resistless force! Some day he would turn it to account. Years after he went to Buffalo, and in the great power plant at Niagara he saw machinery bearing the name of Tesla.

All who were present at the banquet felt, if it may be so stated without bathos, that they had "soared toward the empyrean," for a glimpse of the glory that excelleth; the man in the midst of the fire; the controlling power,

"Half spirit and half bird.
And all a wonder and a wild desire."

DESIRE STANTON.

"Now shine your very brightest," said Dame Nature to the Sun;
"Appear, ye flowers and leaflets, for winter's course is run;
Let every rugged mountain peak in added grandeur rear;
Let everything look pleasant—for the tourist season's near."

("Gazette," Colorado Springs.)

POLYPHASE INDUCTION MOTORS.

In the Tesla motors of this type, made by the Westinghouse Company, the stationary part is permanently connected to the main circuits, and the rotating part has no electrical contacts or adjustments, and no wearing parts except the shaft and its bearings. The bearings are self-oiling. The primary element consists of a hollow cylinder built up of laminated rings of sheet steel, mounted on the inside to receive the conductors. The rings are rigidly supported by the cast iron housing which encloses the primary and forms the frame of the motor. In motors of large sizes the rings are not continuous, but are made up of segments which are dovetailed and are fitted into corresponding slots in a hollow cylindrical shell of cast iron. This shell is held in the cast iron frame of the motor. The conductors are usually machine-wound coils of wire which are thoroughly insulated before being slipped into the slots of the primary iron core. In some of the larger motors a copper strap bent into the proper form is used, instead of wire, for forming the coils. In large motors wound for low voltages, in which the large current requires a large conductor, a copper bar is placed in each slot ; the insulated bars are slipped in at one end and the proper connections between bars are made by short lengths of copper strap. This bar winding is considered to be the simplest and most desirable type of winding. The terminal blocks, through which the leads bring the current to the motor, are connected to the primary winding, and are located at the top of the motor, except in motors of the larger sizes, in which they are located at one side. The secondary is built up of laminated steel discs, made of a high grade of metal, mounted upon an open spider, and carrying in slots around the periphery the rectangular copper bars of the winding. The construction is such that the conductors cannot be thrown out by centrifugal force, the whole secondary being extremely simple, rigid, and durable.

The same general form of construction is used for motors from 1-horse power to 500-horse power. The conductors of the secondary are all purposely short-circuited ; therefore it is evident that no accidental short circuit can possibly occur that will cause injury to the windings. The construction is practically indestructible from heating, raising of coils, or mechanical injury in handling. The constant-speed motors are built for two-phase or three-phase circuits, for 7200 or 3600 alternations per minute, and for capacities ranging from 1-horse power upwards. The voltage is 100 volts for motors up to 3-horse power, 200 and 400 volts for motors up to 200-horse power, and 400 volts for all motors from 200-horse power to 500-horse power. Variable-speed motors are also made, and are used on cranes, &c. The variation of speed between full-load and no-load is very small, and is less than that in direct-current motors. There are no commutators, and no moving contacts of any kind.

The Colorado Springs Evening Telegraph July 29, 1899

TESLA TALKS TO THE TELEGRAPH

"When am I going to make an experiment with wireless telegraphy? Why I don't intend to make such an experiment."

This is what Nickola Tesla, the great electrician, said to a Telegraph reporter this morning when asked how long it would be before he would be ready to make his final experiment. It has been generally supposed that Mr. Tesla built his station for the purpose of telegraphing to the summit of Pike's Peak without the use of wires, but he has evidently changed his plans during his stay here, and has given up the idea of experimenting with wireless telegraphy.

"No, I have worked long enough on wireless telegraphy," continued Mr. Tesla, and I am not experimenting with it now." When asked about the experiments he is making, Mr. Tesla said he would prefer not to make any statements to the public concerning them. The workmen at the station east of town are still busy working on the large induction coil which occupies nearly the entire building. The coil is one of the largest in the world, and when finished will send out over 3,000,000 volts of electricity when necessary. Another smaller induction coil is also in the building, and will be used when a smaller volume of electricity is desired. Twelve large storage batteries were placed around the transmitter today.

When Mr. Tesla was asked when he would make some experiments he replied: "Why, I am making them all the time, and have been experimenting ever since I have been in the city. I think that is about all I wish to say this morning about my work." Mr. Tesla then walked back into his private room in one corner of the station and commenced to figure some problem. Mr. Tesla spends nearly all his time at the station, and several times has been seen with his instruments during the night hours. The electric power which he uses is furnished by the City Electric company, and he is generally unable to get the power in the daytime, and is required to use it at night. The experiments are still conducted with the utmost secrecy, and no one but his employes are allowed near the building.

The Brooklyn Eagle September 7, 1899

TO TEST TESLA'S SYSTEM.

Lighthouse Board to Ask Congress for an Appropriation.

(Special to the Eagle.)

Washington, September 7—The members of the Lighthouse Board intend to ask Congress for an apropriation during the coming session of Congress to enable them to conduct some extensive experiments with wireless telegraphy at Fire Island. This scheme is a popular one with Admiral Higginson and the other members of this board who believe that it will eventually figure prominently in the lighthouse and life saving systems.

Admiral Higginson has already had some correspondence with Tesla, the electrical expert, and others in New York who are interested in this subject, and it is possible that some semi-official tests may take place this fall. The members of the board will work from either Nantucket or Fire Island and the mainland. The greatest difficulty now in the way is lack of funds, no appropriation being available for experiments of any kind.

The New York Tribune September 20, 1899

TESLA'S WORK IN COLORADO.

TO GET ELECTRICAL POWER FROM THE UPPER AIR—EXPERIMENTING ON MACHINE FOR SENDING WIRELESS MESSAGES TO PARIS.

Colorado Springs, Col., Sept. 19.—When Nikola Tesla, the wizard of the electrical world, arrived here early in June for experiments in upper air strata, definite results were expected soon by the general public. Mr. Tesla himself said he might remain here all summer. He now says he has just fairly begun his work, and that he is not contemplating a return to New-York before December, if then, unless it is on urgent business, the trip being just as brief as possible.

"Two objects brought me here," said he. "First, to develop, perfect and manufacture a machine for transmitting messages to Paris next year without the use of wires; second, to work out a theory on which I have been experimenting for five or six years, that there are electrical currents in the strata of air at various altitudes, from which tremendous power can be generated. Some years ago I discovered the principle that power can be transmitted to any distance without wires. The transmission of messages followed close after. Then I discovered a principle to be made of more service. I am only at the beginning, but I was never more confident of success. I never fail."

Tesla has an experiment station just east of Colorado City. He spends there the daylight hours, not stopping for luncheon, and frequently works after nightfall. He has not yet ascended Pike's Peak, which may become important in his experiments. He confidently expects to talk to Paris next year without the aid of wires. He hopes also to perfect inventions for general use in wireless telegraphy.

NOTES AND MEMORANDA.

IN the Tesla Interrupter, the interruptions are obtained by a stream of mercury impinging upon a rotating disc having projecting teeth. The interruptions take place in a gas under pressure, thus permitting a much higher frequency than would otherwise be possible.

Time and space do not permit the discussion of the many other factors which give Colorado Springs its unique climatic possession; for instance, the influence of the far-distant Pacific Ocean on the West and the Gulf of Mexico on the south. There is, moreover, a wide field for speculation as to the influence of the peculiar and intense electrical phenomena exhibited in this vicinity, which we hope that our distinguished visitor, Nikola Tesla, will shortly elucidate for us. We physicians are cognizant of many nervous disturbances of the human economy of whose exact causes we can but vaguely guess. Those who come to us in depressed health usually experience the effects of a powerful climatic tonic, while those who seek these regions for rest and recreation at all seasons of the year, if they have been prudent in their food and exercise, as a rule return to their homes refreshed and strengthened and with pleasant memories of their sojourn in this happy clime.

S. E. Solly, M. D.

The Colorado Springs Evening Telegraph October 7, 1899

NIKOLA TESLA TALKS OF MARCONI'S WORK

Nikola Tesla is about to be heard from again in away that will interest the entire world.

This he says himself, but not in the boastful spirit stated above. He admitted, rather than made the assertion, that he was about to launch a new device for wireless telegraphy.

"My new theory will obviate the difficulty, or rather will not have the defect, that characterizes the present system," he said this morning to an Evening Telegraph reporter.

"You mean the Marconi system?"

"I mean all systems that I know of. I do not wish to disparage, therefore I will not specify. I am familiar with all the devices now being tried, and the defect common is that no operations can be conducted where there is another inductive instrument within a radius of 200 or even 300 miles.

"This is the fatal point with wireless telegraphy, as it now is," continued the great electrician. "It is absolutely impossible where there are other instruments to interfere. Therefore I see no practical value in wireless telegraphy as it is now.

"Another point not at all satisfactory about the present system," said Mr. Tesla "is the number of words that can be transmitted per minute—only twelve," and he smiled.

"I hope," said he, "to perfect a system by which 1,500 or 2,000 words can be telegraphed each minute," and he spoke with that confidence which lends faith.

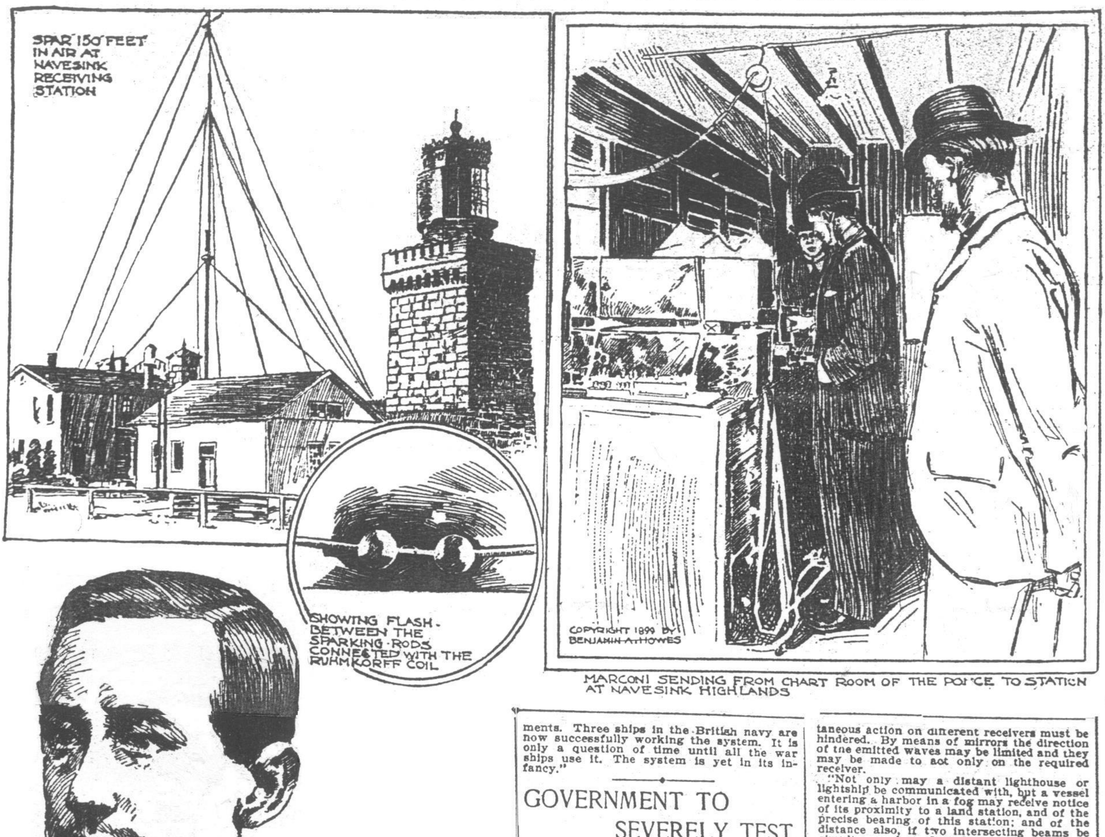
This most important announcement that Mr. Tesla is about to introduce a system of wireless telegraphy that will be without the defects of the systems now being tried was made by the inventor himself in the lobby of the Alta Vista hotel this morning. When he came down from his room preparatory to going out to his experiment station on Knob Hill, he was asked his opinion of the experiments which Marconi has been making in reporting the movements of the Columbia and the Shamrock race. But the great inventor had already been asked the question. The prominent newspapers from all over the country have wired him for a statement regarding these experiments. To all their invitations he has turned a deaf ear.

"I have no time," he said, " to go into this matter. But I am glad to see the interest that is being manifested. There is really nothing novel, you understand, about what Marconi is doing. The experiments are interesting, that is all. I am glad they are so successful as reported, but the system, all devices, in fact, that I have seen described, have this fatal defect—they are of no value where powerful inductive instruments are stationed within a radius of 200 miles of the point of operations. Under such circumstances it is impossible to exchange signals."

Then it was that Tesla told, in a very modest way, about his hopes of a perfect system; more than hopes, in fact; he actually stated that in a short time he would submit a plan to the scientific world in which these defects would be overcome.

"I have already overcome the great defect," he said, ::and I will have something to say very shortly."

The constant and nerve-straining work which Tesla has been doing at his experiment station is telling on his health in this high altitude. He has been feeling ill of late and regrets that the corditions are somewhat unfavorable to his health.



"It is the hours I keep," he said, "but I cannot change them. The night is my workday. It was in New York until 2 and 3 o'clock every morning, and I cannot cannot change my habits here, even though they are so unfavorable. I think the best time for working here would be early in the morning, say about 4 o'clock, and then retire early at night, but I could not accustom myself to those hours."

There is probably no more interesting character in the scientific world than Nikola Tesla. He has already astonished it with several inventions of a most important nature, and he is yet confident of doing the greatest things it is possible to imagine. While all Colorado Springs, indeed half the world, is sleeping, Tesla is manipulating electric currents in a little place out on the prairies east of town. There is something wierd and yet nothing unreal about this man who manufactures lightning bolts, whose happiest moments are during an electrical storm when the wires about him snap and light up on all sides, when it would seem his life is in danger. No one will doubt a man like this when he says:

"I will be heard from."

WIRELESS SYSTEM MAY BE USED IN PHILIPPINES

MARCONI AND PART OF HIS WIRELESS TELEGRAPHY APPARATUS.

MARCONI SENDING FROM CHART ROOM OF THE POLICE STATION AT NAVESINK HIGHLANDS

have always referred them to the police, as I have had full confidence in my ability to protect myself from interference. I can so individualize my stations that it would be almost impossible to disturb them.

"On the other hand, I am convinced that it would be possible to start in the atmosphere an electric commotion that would demoralize the entire telephonic system of any city. Indeed, it was done in Glasgow by an experimenter. He had an idea of using coils of wire from which to send signals through the air. His success was not entirely satisfactory, but, without intending to do so, he temporarily put the telephone system of the city out of business.

Not Afraid of Interference.

"It has been said that this is one of the weak points of the wireless telegraph. I can answer that our machines are less easily affected than are telephones. The currents that would play havoc with the telephone would make no impression upon the wireless telegraph.

"Have I ever given study to any other branch of practical electricity? Certainly I have, but I have dropped it all for the present. After the wireless telegraph has been fully developed I will take up something else with which to busy myself. I have many crude plans in mind, but of that I would rather not talk at present."

EDISON PREDICTS A GREAT FUTURE.

Sure of System Being Valuable at Sea—Suggests Use of Kites.

"He succeeded where I failed." This is the tribute paid to Signor Marconi by Thomas A. Edison. I called on Mr. Edison yesterday, at his home, in Llewellyn Park, and, although it is his general rule never to grant interviews on Sunday, reserving that day for himself, he consented to talk about wireless telegraphy for the HERALD. When asked what he thought of the system, Mr. Edison said:—

"There is certainly a great future ahead of it. What that future may be no one can say. It would seem as if we were approaching the limit, but then, so it was thought a long time ago. What that limit will be no one knows.

"Mr. Marconi has proved that the electrical waves can be jumped around the curvature of the earth, and this has heretofore been an insuperable obstacle. With this accomplished there is apparently no end to the distances that can be overcome. So far it seems as if about two hundred miles was the limit, but yet even this distance may be as nothing in the future."

"Is the system a new one or is it only an adaptation of old principles?"

"The idea is not new, and others have been experimenting along that line. I had patents out on this line long before we heard of Marconi. I tried experiments at Menlo years ago and kept at it for a long time, but I could not get over the obstacle of the curvature of the earth, and about two miles was the limit that I could reach. Telegraphing from moving trains was the line of my invention, but I and all others ran up against obstacles that could not be overcome."

"What is your estimate of the practical value of the invention?"

"Well, it will prove of great value in a maritime direction, but I cannot see that, as at present developed, it will be of much value in land operations. The system can be made of great practical use in sea service by stationing vessels or tugs a certain number of miles apart, but near enough to each other to come within the sphere of electrical influence. In this way lines of communication could be established for a thousand miles or more. Islands could be connected in this way, or, perhaps, groups of such islands brought into close communication with each other.

"It is possible that some valuable use might be made of the system on land, and, indeed, some time ago in the manœuvres of the British army and fleet the wireless system worked well. Possibly the use of aeroplane kites in connection with the system may be found to have a practical value. All this is yet to be developed."

"Are you working at all on this line?" the inventor was asked.

"No," he replied. "I gave the whole thing up years ago and have dismissed it from my mind. Perhaps one of these days I may take it up again, but that is a contingency too remote to speak of."

FIELD ENTIRELY NEW AND ITS OWN.

New York Experts Predict Many Practical Uses for System.

That wireless telegraphy has been brought to a practical stage and will soon be used as an additional means of communication on land and sea was the unanimous opinion of electrical experts who viewed its workings Saturday on board the Mackay-Bennett off Sandy Hook. There was some difference of opinion as to the extent of its application, but all agreed that it would take an important place in commerce and warfare.

Charles Cuttriss, an expert of the Commercial Cable Company, said:—"The wireless telegraph is one of the greatest inventions of the age. As to its practical applications, it will have a field entirely its own. Wireless telegraphy will not interfere with existing systems of telegraph communication. It will never take the place of the submarine cable or land telegraph lines.

"It will afford an invaluable means of communication, however, between points where the maintenance of telegraph wires would be impracticable. Wireless telegraph stations could be established on outlying points and islands. Passing ships that had the wireless equipment could send messages to these stations, and they in turn could send them to their destinations by the ordinary method. Vessels could receive messages from shore and could communicate with one another and give warning if in distress. In this way alone the system would be of inestimable value.

"The cost of equipping vessels would not be great. It would be a great convenience and great safeguard if all ocean liners were provided with instruments."

Thomas Commerford Martin, editor of the Electrical World and Engineer, said:—

"In view of the tests to which the wireless system has been submitted it seems safe to assume that it has reached an entirely practical stage and is ready for application to everyday work. The successful results obtained during the yacht races are the more interesting because the work has not been undertaken as a test of the system, but as an application of its practical purposes, not differing in this respect from the arrangement made to transmit the messages by cable from the receiving ship to the shore. There can no longer be any doubt as to the success of wireless telegraphy."

Charles Priest, electrician of the Mackay-Bennett, said:—"Wireless telegraphy will no doubt fill an important place in a field distinctly its own. It will never take the place of cable or land wire communication, but as a means of communication between ships and between points on shore which it would not be practicable to connect by wire it will be invaluable."

Minor M. Davis, traffic manager of the Postal Telegraph Company, said:—"The application that is being made of wireless telegraphy during the yacht races has proven that it is practicable. There is no doubt that there is a great field open to it. If ships are to use it as a means of communication it will be necessary to synchronize the instruments, so that different ships within the same radius can communicate with one another simultaneously, without the messages being confused."

T. Bowden, who receives the wireless messages on the Mackay-Bennett, said it was not claimed that wireless telegraphy would take the place of the great telegraph systems. He added:—

"Its greatest service will be as a means of communication between ship and ship, and ship and shore. It will prove a great safeguard to navigation. Fog does not interfere in the slightest with the wireless communication.

"The cost of equipping ships would be comparatively light. Experts are not required to work the instruments. Ordinary lightship men are now working it in England. So there is no reason why freight as well as passenger ships should not have the instruments. Three ships in the British navy are now successfully working the system. It is only a question of time until all the war ships use it. The system is yet in its infancy."

GOVERNMENT TO SEVERELY TEST.

Important Experiments Will Be Made by the Army and Navy Authorities.

HERALD BUREAU, CORNER FIFTEENTH AND G STREETS, N. W., WASHINGTON, D. C., Sunday.

Convinced of the practical value of wireless telegraphy by the successful reporting of the yacht races, arrangements have been made by the government for experimenting with the system which may lead to its adoption in several important services.

After the yacht races Rear Admiral Bradford, chief of the Naval Bureau of Equipment, expects to confer with Mr. Marconi relative to the naval experiments. It is understood that the cruiser New York and battle ship Texas will be equipped with instruments and a shore station will be established at Atlantic Highlands.

Negotiations are in progress also between the Signal Corps of the army and Mr. Marconi for experiments to demonstrate the use of the system on land.

Experiments have already been made by the life saving service, but the result has not been decisive. If satisfactory, life saving stations and lighthouses will probably be equipped with instruments.

The experiments to be made by the army and navy will be exhaustive. To quote officials with whom I talked, the yacht race reports have shown that the system is practicable for general operation at sea; it only remains to prove whether it will be satisfactory for naval and military purposes. If a success it will be adopted by the navy, and the army in the Philippines will be equipped with instruments. The lighthouse and life saving services will also adopt it, and merchantmen will be advised to equip their ships in order that they may communicate with the shore in case of disaster.

The naval experiments will be made under the general direction of Rear Admiral Farquhar, who will succeed Rear Admiral Sampson in command of the North Atlantic squadron. The officers now witnessing the operations of the system in connection with the yacht races will conduct the experiments at sea. Speaking of the matter to-day, Admiral Bradford said:—

"There is no question of its prospective value. I am not yet prepared, however, to say how great that value will be. The officers who are witnessing the present trials have not submitted their reports."

Colonel James Allen, acting chief signal officer of the army, states that two automobiles recently bought will be used in the army experiments. Small balloons and kites will be employed, and their use may increase the distance over which a message can be sent. He said:—

"The value of wireless telegraphy increases as the square of distance. Thus, if a message can be sent fifty miles and given a value, for instance, of two, its despatch over one hundred miles would make the system worth four. Should the system operate satisfactorily over one hundred miles, communication by wireless telegraphy could be maintained between Key West and Cuba, between the islands of the Hawaiian group and between some of the islands of the Philippine archipelago.

"The best results with the system have thus far been obtained over water. No satisfactory results have been secured over wooded country. Naturally we are hopeful that the experiments will show that the system can be operated on land. It will then be highly valuable in maintaining communication between operating columns, between such columns and their base and between besieged and their friends. In case the system proves successful, instruments and the necessary appliances will be sent to Manila."

Chief Moore, of the Weather Bureau, is another government official who is watching the experiments with wireless telegraphy with much interest. The officials of the bureau look forward to the possible use of the invention in gathering information regarding the weather and sending out forecasts and storm warnings.

WILL SUPPLEMENT EXISTING SYSTEMS.

Professor Suggests That News May Yet Reach Steamer in Midocean.

PHILADELPHIA, Pa., Sunday.—Dr. George F. Barker, professor of physics in the University of Pennsylvania, says of wireless telegraphy:—

"So far as my investigations have gone, they lead me to the conclusion that while wireless telegraphy is entirely possible practically, it is adapted to supplement rather than to displace the existing telegraph systems.

"The possibility of transmitting intelligence electrically through space between distant points without having these points connected by metallic conductors is beyond question. Moreover, improvements are rapidly being made. As transmitters multiply, their simultaneous action on different receivers must be hindered. By means of mirrors the direction of the emitted waves may be limited and they may be made to act only on the required receiver.

"Not only may a distant lighthouse or lightship be communicated with, but a vessel entering a harbor in a fog may receive notice of its proximity to a land station, and of the precise bearing of this station; and of the distance also, if two intersecting beams be simultaneously reflected.

"In the very near future the news of both continents may be received in midocean on our Atlantic liners, and so a newspaper may be published daily."

WILL FIND MUCH USE IN WARFARE.

Chicago Electricians Point Out Value of System in Military Plans.

CHICAGO, Ill., Saturday.—It is the opinion of leading electrical experts in Chicago that wireless telegraphy is one of the most valuable scientific discoveries ever given to the world. B. E. Sunny, manager of the General Electric Company, in speaking of the system said:—

"To say that it will affect the present system of telegraphy would be wrong, in my opinion. It will occupy a distinct field of its own, as the present methods of transmission of intelligence are near perfection.

"The wireless system will prove of inestimable value for the signalling of ships at sea, and will be of great service to armies and navies, and for sending messages over land and water where telegraph wires cannot be run. Railroads will find use for the new system in the emergency of a disaster between stations, but for commercial purposes the wireless telegraphy will never displace the obtaining methods."

Professor Francis B. Badt said:—

"I have unbounded faith in the success and practicability of the wireless system. The idea, though, in my opinion, is only in the first stages of development. The very satisfactory results from the experiments at the yacht races demonstrates the possibilities of the device for use over short distances, and whenever a method is found by which the energy lost in the wave current can be conserved the distance will be extended accordingly. I expect that this improvement will come before long.

"There will be no revolution in the old system of telegraphy. The wireless method would not be practicable in settled localities, where obstructions would interfere with the passage of the current. In all kinds of signalling on the water the service will be of great help. Military movements will be facilitated by the use of the wireless system. It will have a world of its own in which to operate.

IMPORTANT ADJUNCT FOR LIGHTHOUSES.

Professor Dolbear Thinks Wireless Telegraphy Is in Its Infancy.

BOSTON, Mass., Sunday.—Professor Amos E. Dolbear, of Tufts College, is sanguine as to the future of wireless telegraphy. He said in an interview:—

"The art of electrical communication without the use of wires or other conductors stands to-day where the art of telephoning stood in 1877. At that time the telephone was a demonstrated success, but needed improvements in the apparatus to make it available for commercial use. In 1877 it was possible to telephone twenty-five miles, but beyond that distance no satisfactory results could be obtained. Soon afterward, by the means of the Blake transmitter and other improvements, the efficiency of the telephone was increased, until it can now be used for talking a thousand miles.

"There is no storm, in my judgment, which would prevent the use of wireless telegraphy.

"Of course, the commercial use of wireless communication will greatly increase when the message can be individualized and the waves concentrated, as the light waves are in a searchlight. This, I believe, will be speedily done."

Professor John Trowbridge, of Harvard College, said:—

"As a scientific man, I would not take the position that great progress in this means of communication was impossible. At present it is possible to use wireless transmission for a limited amount of work, if there is no opposition. The waves are like light waves, travelling with the same velocity, but of greater length, sa, two or three feet long. By using poles 200 feet high, messages can be sent eighty or one hundred miles, but beyond that distance the curve of the earth's surface sends the waves floating off into space. If the suggestion is made to raise the height of the pole beyond 200 feet, the work of transmission meets with great difficulties in the more active electrical conditions that exist in the higher air.

"It is impossible to relay wireless telegraphy, so that one hundred miles may be taken as the extreme limit of its work. Restricted to this distance, it cannot compete with the regular telegraph in speed or certainty. Wireless telegraphy would undoubtedly be affected by thunder storms and other electrical disturbances, although wind, rain or snow would not disturb it. For use on lightships and other isolated points it will have a practical value, and also in some cases for use between ships at sea."

The New York Herald October 9, 1899

FRIENDS OF TESLA SAID TO FEAR FOR HIS HEALTH.

Inventor, Who Is at Colorado Springs, Says He Hopes Within a Short Time to Announce a Perfect System of Wireless Telegraphy.

DENVER, Col., Sunday.—"I hope within a week or two to announce to the world a system of wireless telegraphy that will be nearly perfect," said Nikola Tesla last night at Colorado Springs. Mr. Tesla has been working between fifteen and twenty hours a day for several weeks. Mr. Tesla's health is plainly impaired, and he announces with satisfaction that his task is almost completed.

"I will not disparage the Marconi system," continued the scientist, "but every system in use at the present time has a serious defect in that its action is disturbed by similar instruments within a radius of a greater or less number of miles. Besides, twelve words a minute seems to be very fast time.

"With the system I have about completed I hope, to attain by mechanical methods a speed of fifteen hundred or two thousand words a minute, and further, to have instruments absolutely free from extraneous disturbances. I have succeeded in eliminating outside influences and can make one set of instruments work free from another almost within touch.

"Marconi's experiments are interesting, but they are not new. I am glad they are being so successfully employed in the yacht races, but it is by no means improbable that before the next international race is pulled off, boats, propelled by wireless power transmission will followed the races, and I hope the yachts themselves will have wireless telephones on board."

Mr. Tesla's experiments with the wireless transmission of power seems to have passed beyond the experimental stage, but he refuses to talk about the subject until after the announcement of his wireless telegraph system.

Among the friends of Tesla much concern is felt for his health, which, they fear, breaking down under the strain of only four or five hours' rest daily. They think there are signs of lung trouble.

Tesla ridicules such ideas, except to admit that he is very tired, but says he expects to take a rest by working only twelve or fourteen hours a day after his wireless telegraph system is completed.

Personal.

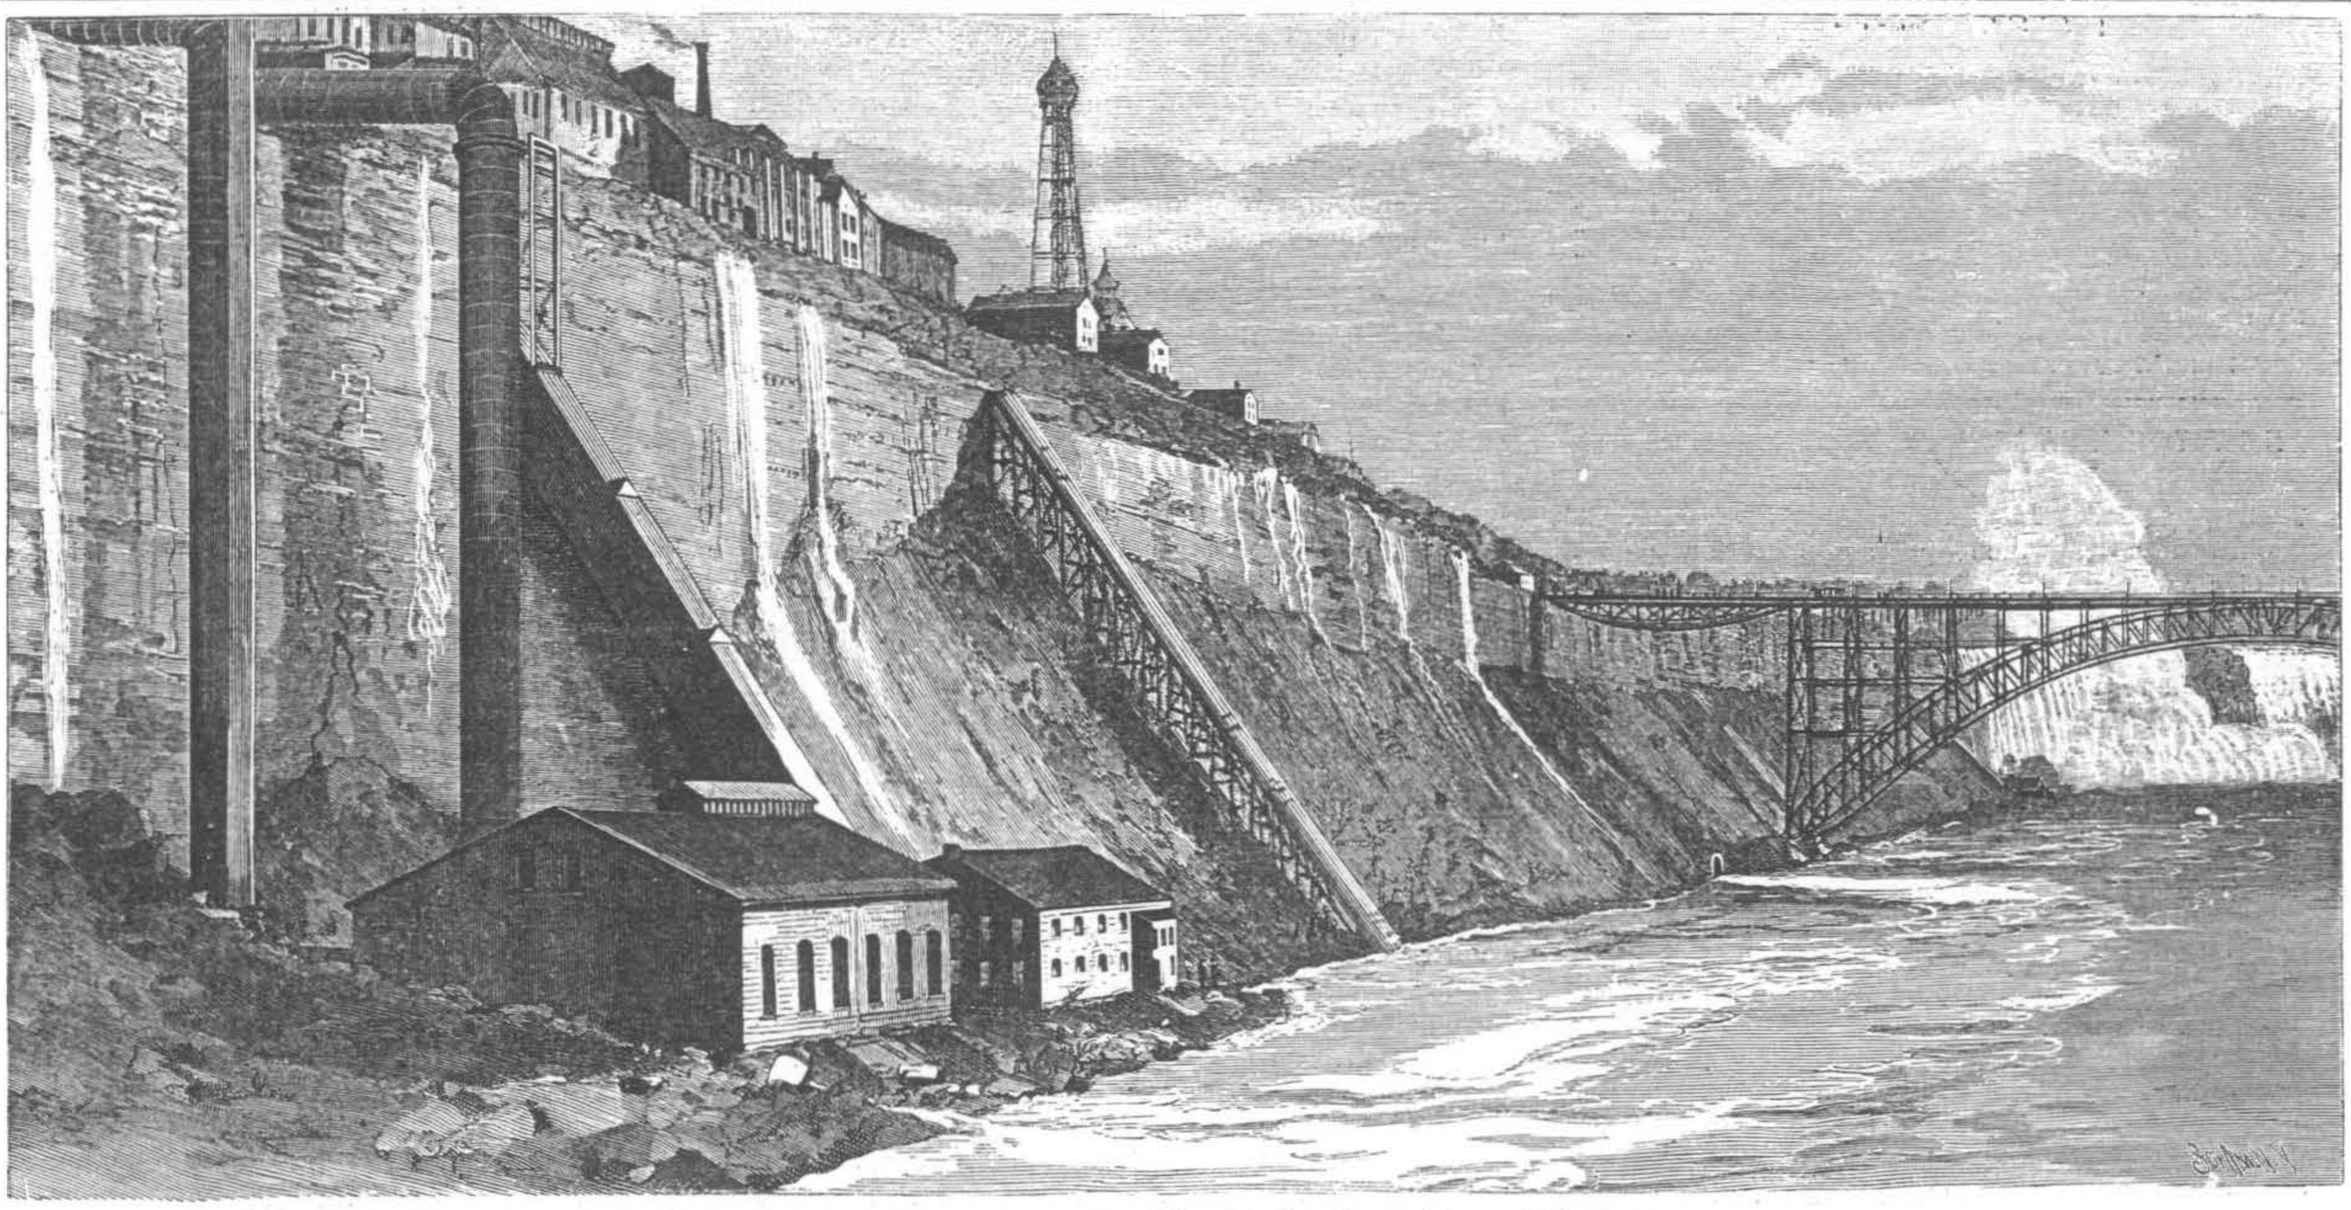
NIKOLA TESLA is still experimenting with wireless telegraphy at Colorado City, Colo.

NOTES.

Tesla Patents.—The Tesla Electric Company of New York have recently been successful in a lawsuit against a Philadelphia firm for infringement of the Tesla patents for multiphase motors.

Tesla Patent Case Decided.

An opinion has been handed down by Judge McPherson of Philadelphia in favor of the Tesla Electric company in the equity proceedings which it brought against Scott & Janney and others. The bill charged the defendants with infringing letters patent Nos. 511,915 and 555,190, relating to polyphase motors, granted to the plaintiff as assignee of Nikola Tesla. The first patent was granted for a method of electrical transmission and the second for an alternating motor, but both patents stand upon the same application and were attacked together on the ground that they were void for want of invention. It was argued that in view of the prior state of the art, and especially in view of an earlier patent of Tesla, the step from obtaining separately from the generator the two alternating currents, different in phase, that are required to operate the motor described in the earlier patent, to obtaining only one of such currents from the generator, while the other is obtained by induction from the primary current, was an obvious step, easy to be taken by anyone possessed of skill in electrical engineering, and therefore did not involve invention. Judge McPherson concluded that the step was taken in the exercise of invention. In concluding his opinion on this point of the defense he said: "So far as I can realize the situation, the two patents now attacked seem to me to be so connected with the earlier group that the same faculties that were necessary to produce those that are first in point of time must have continued in exercise to produce those that followed. It is often very difficult to draw the line between invention and skill, and different minds may draw it at different points. I submit my own conclusion for what it may be worth."



Judge McPherson held that none of the defenses submitted to the court could be sustained and that the motor of the defendants infringed all of the disputed claims involved in the suit. The patents in question are now owned and controlled by the Westinghouse Electric and Manufacturing company.

NEW YORK, SATURDAY, NOVEMBER 11, 1899.

THE ELECTRIC POWER PROBLEM OF NIAGARA.

With the article which appears on another page of this issue we close the series, on Niagara Falls as an industrial center, which has appeared at intervals during the present year, and it will now be opportune to sum up the results which have been accomplished, and see how far they agree with the expectations which were formed when the "harnessing" of the Falls on the present extensive scale was seriously undertaken.

In the first place it must be understood that the generation of fifty thousand electrical horse power was not attempted primarily with the expectation of transmitting it to far distant centers, there to be redistributed for local use. It is true that this was popularly supposed to be the object aimed at in the Niagara Falls Power Plant, and in the early days of its construction, writers were accustomed fairly to revel in picturesque descriptions of the silent flow of Niagara's energy to cities as far distant as Chicago and New York, where it was to displace every existing form of power by virtue of its extraordinary cheapness and convenience.

As a matter of fact, however, the eminent specialists and financiers who had the courage to build such a vast electrical plant did not undertake to generate this unprecedented amount of electrical energy with the idea of transmitting it *in toto* to far distant centers. Not only was the art of long distance transmission at that period in its comparative infancy, but it was foreseen that better economic results would be achieved in bringing the industries to the source of power rather than in carrying the power to the industries. As between the two alternatives, there were on the one hand the great cost and losses of transmission, and, on the other, the question of cheap railway and steamship transportation both for the raw materials and the finished product. The original promoters considered that, in respect of transportation facilities, the proximity of the Great Lakes and the convergence of several important railroads at Niagara rendered this an ideal manufacturing center, and, acting upon the conviction, they purchased large blocks of land contiguous to the power station, with the intention of renting the same for the erection of industrial establishments, which in the course of time were certain to be attracted by such an abundant electrical supply. At the same time, the company wisely determined to design the electric installation with a view to meeting the varied needs of its customers, and arrangements were made to supply, within reasonable limits, any kind of electric current that might be required.

That the expectations of the company were well founded is seen from a study of the facts presented in the series of articles in the SCIENTIFIC AMERICAN above referred to. In the few years that have intervened since the water was first turned into the wheelpit of the Niagara Falls Power Plant, a large number of entirely new industries have sprung up around, or within easy touch of, the station; while establishments that were already existing have become extensive users of the power. That the tendency is for the industries to gravitate to the power rather than the power to be transmitted to the industries is shown by the fact that out of a total of 35,000 horse power delivered from the station, over three-fourths are consumed in its vicinity, as against less than one-fourth that is transmitted to a distance—the principal long distance transmission being that of 8,000 horse power to Buffalo, for the use of the Cataract Power and Conduit Company.

Although the natural trend of events, controlled by well understood economic laws, has brought about a centralization of industries at the falls, it is not to be inferred that long distance transmission will not enter largely into the ultimate utilization of the energy of Niagara. In the few years since construction was first started a great stride has been made in art of generating and manipulating electrical currents for transmission, and the remarkable installation recently opened in Southern California, where a transmission of 83 miles has been successfully accomplished, suggests that a large part of the 7½ millions of hydraulic horse power available at the falls may yet be transformed and transmitted to the large cities of the East. The present indications are, however, that for some time to come transmissions are not likely to be attempted for distances of over 100 miles. The difficulties are not now so much of a physical nature (thanks to the alternating current of high potential), but are largely economical—the great cost of the line rapidly offsetting the cheap cost of production at the power station. The power from the falls could to-day be transmitted to a distance of 100 miles with a loss of 20 per cent; and in spite of this loss and the great cost of the line, it could compete successfully with steam power at a cost of $60 per horse power per annum.

NIAGARA FALLS HYDRAULIC POWER PLANT.

In the present number we conclude a series of articles on Niagara, the first of which, on "Niagara as an Industrial Center," appeared in our issue of May 27. On June 17 we illustrated the many handsome bridges which have been thrown across the Niagara gorge in the past fifty years, and on July 22 we gave a lengthy description of the 50,000 horse power electric plant of the Niagara Falls Power Company. In the first-named article it was shown that taking into account all the turbines that are at present in use, big and little, of the total theoretical horse power of 7,500,000 at the falls, only about 50,000 horse power is at present being developed and actually utilized, either as hydraulic or electrical power, for industrial and transportation purposes. This total, however, is constantly being increased, as the various additions which are being made to existing plants are brought into operation; and it will not be many months before the total amount of power developed will have increased by fifty per cent.

So much attention has been directed to the Niagara Falls Power Plant, with its present capacity of 40,000 horse power and actual output of from 20,000 to 30,000 horse power, that the public has not realized the size and rapidly growing importance of the Niagara Falls Hydraulic Power Plant, which has at present a capacity of 13,000 horse power, and has an enlargement under way which will increase its total capacity to 20,000 horse power. The method of developing the hydraulic power differs widely from that which has been employed with the Niagara Falls Power Plant, where, it will be remembered, the water is led in from the river above the falls by a short length of canal to the power house, and delivered through penstocks to a set of turbines which work under a head of 135 feet. The tailrace for the latter consists of a great tunnel with a fall of 50 feet in a length of 7,000 feet, and the water is finally discharged into the lower river at a point below the falls.

In the case of the Niagara Falls Hydraulic Power Plant, the water is taken from the river above the falls by an open canal and led to a point about a mile below the falls, where it passes through penstocks to turbines that are situated within a power house, which is built close to the water's edge at the bottom of the gorge, as shown in the two illustrations on the first page. The advantage of the latter system is that the effective head is considerably increased, the loss of the head in the tunnel being 50 feet and in the canal only 2 feet. By suitably constructing the tailrace, an additional head of several feet is secured below the turbines, with the result that the total effective head of the hydraulic power plant is 210 feet. The total length of the surface canal is 4,400 feet, its present width at the entrance is 250 feet, and in 400 feet the width narrows down to 70 feet. At this width it continues into a basin which is located about 300 feet back from the edge of the gorge above the power house. The basin runs parallel with the edge of the cliff and is about 400 feet long by 70 feet wide. The company owns sufficient right of way to increase the width of the canal to 100 feet, if it desires to do so. For 40 feet of the present width of the canal the channel is 14 feet deep, and for the remaining 30 feet it is 8 feet deep. The work of widening the canal is now in progress.

The power house is a substantial building of stone with a steel truss roof. Water is led down to the power house by means of two penstocks, one of which is 8 feet and the other 11 feet in diameter. The original section of the building was completed in 1896, and an 8-foot penstock serves to convey water to four Leffel turbines, of 2,250 horse power each, which operate eight generators, six of which supply power to the lower works of the Pittsburg Reduction Company, while the other two furnish power for the operation of the Niagara Falls and Lewiston Railway, better known as the "Great Gorge" route, illustrations of which will be found in the SCIENTIFIC AMERICAN of March 28, 1896. The operation of the original installation was so satisfactory that a large addition was immediately commenced, and the building was increased

to the size shown in our illustration. It now measures 100 feet by 120 feet. The addition to the plant consists of five wheels of the Jonval-Geyelin type, each of 2,500 horse power. Our illustrations show one of the new wheels in place. These wheels are fed by a new 11-foot penstock, which has a capacity of 12,000 horse power. It leaves the forebay with an elliptical bell mouth which measures about 20 feet by 11 feet, and is carried out horizontally from the cliff, supported on two heavy steel beams for a distance of 60 feet, and then drops vertically nearly 200 feet to the power house. For about fifty feet of its length beneath the power house floor it is 13 feet in diameter, and, after passing beneath two of the wheels, its diameter is reduced to 7 feet, beyond which point it tapers off into a cone 18 inches in diameter, and finally ends in an air-chamber, which is 4 feet in diameter by 15 feet in height. The object of the air-chamber is to cushion the vertical movement of such a great mass of water and prevent injurious shocks to the machinery. The steel used in the construction of the penstock varies from a thickness of $\frac{5}{8}$ of an inch at the top to $1\frac{1}{8}$ inches at the bottom.

Above the horizontal portion of the penstock beneath the floor are carried a series of five 60-inch hydraulic valves which are placed horizontally and serve to conduct the water from the penstock up to the five turbines which are placed immediately above them. These valves, with their supporting girders, are shown in the lower illustration of our first page. The water flows through the valves to the turbines and is admitted by a gate to the guide-wheels, and through them to the runners. From the sides of the turbine the discharge pipes project laterally and then downwardly to connect with draught tubes 22 feet 8 inches in length, the use of which makes it possible to utilize in part the atmospheric pressure, and increase the effective head of the turbines accordingly. The turbine wheels are made of bronze, and they are located in the draught-tube casing, one on each side of the casing proper. The pair weighs 5.095 pounds. They are mounted upon a horizontal shaft and are directly connected to a general electric generator, which supplies current to the new chlorate of potash plant of the National Electrolytic Company, located on the top of the cliff.

A walking-beam, working over the main casing, operates the gate which is connected to the beam by $2\frac{1}{2}$-inch rods extending down through the glands into the casing. Above the walking-beam is an air cylinder 36 inches in height, with a diameter of $20\frac{1}{2}$ inches. The turbine is controlled by a Reynolds governor. It should be mentioned that there are thirty-four buckets on the runners with a total area of 140·25 square inches. On the guide-wheel there are twenty buckets with a total area of 149·53 square inches. The General Electric Company's generator is shown in our illustration. It has fourteen poles and runs at 257 revolutions per minute, giving an output of 5,000 amperes at 175 volts. This represents a capacity of 875 kilowatts or about 1,200 horse power. The current is carried to the chlorate of potash works on aluminium cables, the lower part of which is made in bar form and the upper part in the form of well insulated cables. The dynamo for the Buffalo and Niagara Falls Electric Light and Power Company is of 700 kilowatts output capacity at 2,200 volts pressure.

The completion of the five Jonval-Geyelin turbines will raise the total horse power at this station to 20,000, but it is intended to build another 11-foot penstock and increase the total horse power of the plant to 30,000, which will be the maximum that can be developed from the present upper basin. Ultimately, however, it is intended to extend the basin along the cliff beyond the present factories of the small users of the company's water power, and carry down other penstocks to a new power house at the edge of the river. The company has sufficient room to install a total of 100,000 horse power, which is well within their grant of 125,000 horse power. The present capacity of the canal is about 40,000 horse power, but the company has a force of dredges which are continually at work enlarging and deepening it.

Visitors to Niagara will have noticed the cascades of water which fall from the side of the cliff in varying quantities in the immediate neighborhood of the company's power house. These streams are the tailraces of the various smaller factories which are built at the edge of the cliff, and take water from the company's basin behind them. The turbines operate under heads of from 60 to 100 feet In some cases they are sunk in wheel-pits and discharge through tunnels, while in others a cutting is made through the face of the cliff. The total hydraulic power thus developed is about 7,500.

This brings us to the close of a subject which we have treated at considerable length because we believe that there is a great demand for complete information upon a matter of such importance as the utilization of the energy of the falls.

Isolated statements of work done in this or that establishment at Niagara Falls have been published from time to time, but these are not sufficient to give such a comprehensive view of the subject as we have endeavored to set forth in these articles. While the work of developing this great source of hydraulic power has not gone forward with the rapidity which was popularly expected, it must at least be admitted that what has been done has been carried out on conservative lines and with such a measure of success as promises well for the future.

TESLA Hopes to Telegraph from New York to Paris Without Wires.

After Months of Experimenting in Colorado Says He Has Solved the Problem.

NIKOLA TESLA, who opened an experimental station in Colorado Springs, Col., in May last for the purpose of making scientific measurements and observations with wireless telegraphy in high altitudes, has successfully concluded his work and will soon return to this city to continue his work here. He has perfected a machine by which he intends to send messages to Paris next year, and his experiments here will be in communication by means of the machine with Paris, without the use of a wire.

"I have been successful in my experiments beyond anything I ever accomplished," he said to a correspondent for the HERALD. "I am glad I have come to Colorado. I am delighted with the results. I am not at liberty to give out the details of my work at this time, but you can say the system of wireless telegraphy has been successfully demonstrated in this altitude, which is 6,000 feet above sea level."

Since the establishment of his laboratory in Colorado Springs Mr. Tesla has lived at the Alta Vista Hotel, but he is seldom seen there.

The Colorado Springs laboratory in which Tesla has been so successful is located about a mile from the centre of the city, on the highest point of land in that vicinity, and is on a direct line east from Pike's Peak. It is about two hundred feet higher than the town proper, affording an unobstructed view of the Rocky Mountains.

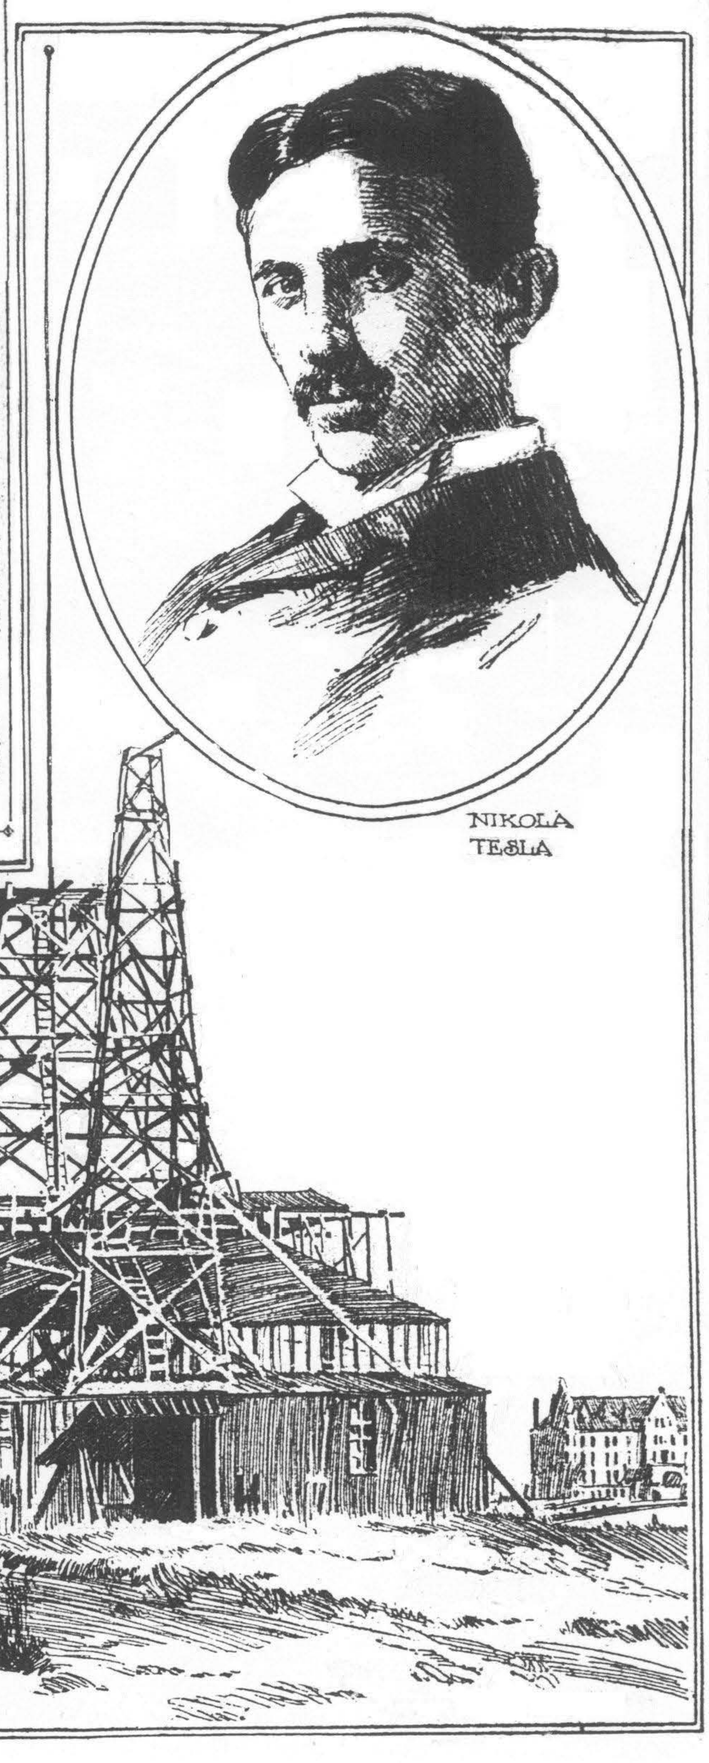
It is not enclosed, and although located only a few hundred feet from a street, Mr. Tesla has obtained all the privacy desired, as he has placed about the building numerous signs bearing the following inscription:—

GREAT DANGER! KEEP OUT!

The laboratory is a queer looking structure and has been an object of interest to the townfolk, who have gazed at it long and often, but who, as a rule, never ventured closer than fifty feet, the sign being a sufficient warning to keep away the curious.

The most noticeable features about the barnlike building are the numerous electric wires running into the place, the scaffoldlike contrivances on the roof, and the pole in the centre of the building, rising to a height of 250 feet, and surmounted by a large ball.

Few persons looking at the ball suspended at the top of the innocent looking pole would imagine that it has played the important part in high altitude experiments. The ball, which is about one and a half feet in diameter, is used to transmit and receive messages. There is a wire on the inside of the pole which runs to the instrument in the building.



Tesla zealously guards all approaches to the laboratory. There is a small engine near the entrance. The laboratory proper is located back of the engine, and is enclosed by a circular partition, so that employes will not come in contact with "live" wires.

The laboratory consists of two large cylindrical shaped contrivances. One reaches from the floor to the roof, and is made entirely of wood. Surrounding it is one which is encircled by "live" wires, and it is here where Mr. Tesla has accomplished his scientific experiments in a high altitude.

The building, from an exterior point of view, is of peculiar design. It is a low, wooden building thirty feet square, and rises to a height of only twenty feet. The building to the right is the Printers' Home, founded by Messrs. Childs and Drexel, and maintained by the International Typographical Union.

Rising from the rof of the Tesla laboratory are two wooden scaffoldlike arrangements, one being over the centre of the building and the other over the doorway.

As Mr. Tesla was conversing with the HERALD correspondent a man entered with a sample of paint. Tesla smiled and said, "I wish I had had that paint before, as my laboratory here has been on fire five times and has been struck by lightning six times. Happily no damage was done."

NIKOLA TESLA

EXPERIMENTAL STATION AT COLORADO SPRINGS.

PRIMITIVE WIRELESS TELEGRAPHY.

System Used in Warfare by Oriental Tribes, Who Know of Enemy's Movements Hundreds of Miles Away.

THE army and navy might avail themselves of a system of wireless telegraphy perfected in an entirely unsuspected quarter of the world," said a well known psychic the other day. "It is a system destined to become universally employed for military, commercial and social communication.

"The other day there arrived in this country a little yellow book, by Richard Kerr, Fellow of the British Geographical Society, entitled 'Wireless Telegraphy,' which treats of the history of that art which now has the civilized world by the ears.

"Here are given well authenticated facts concerning mysterious war signals and reports of movements of troops despatched by certain Eastern natives across distances of hundreds of miles without visible electrical or other mechanical appliances. The facts are presented on authority of many officers of European armies engaged in Eastern wars.

"This wonderful system was noticed particularly during the recent war in Afghanistan. Whenever the British officers conveyed to their subordinates particulars as to their intentions to operate at a certain point fifty or a hundred miles away, the natives in those distant quarters were immediately acquainted with all of their plans. This fact was proved by constant repetitions of the feat, and it was seen to our satisfaction that none of our mechanical methods of communication or transportation were used.

"There were no connecting railroad or telegraph lines, and not even the fleetest horseman could have made the trip in the space occupied by the mysterious transmission of intelligence. The outlying hilltops were watched day and night for possible signals, but disclosed nothing.

Secret Well Kept.

"A fund was subscribed among the British officers with which to bribe the natives. Although they acknowledged their power, money could not purchase the secret. They said it was a religious heritage, which could not be imparted to the heretics of the West.

"Kerr publishes statements of British officers that on the day when England lost the illustrious General Gordon at Khartoum several people in the streets and bazaars of Cairo knew of his death. Yet there was no railway or telegraph between these cities. The distance in a direct line was one thousand miles or more.

"A Dutch official now in Amsterdam is quoted as saying that in the Dutch East Indies the natives of any one island knew everything of importance that occurred in any of the other islands, situated, as they all were, miles apart. If there occurred an earthquake or storm involving shipwreck and loss of life, or if a murder had been committed many miles away, the natives on the island on which this official resided would know all of the particulars long before the tidings could be conveyed by the ordinary channels.

"My explanation? Well, it is the same as that of Professor Kerr. He says that these Oriental methods of wireless telegraphy must rest entirely upon a highly trained mental effort. That is just it in a nutshell. Can you estimate the value which a corps of those Eastern wireless telegraphers would be to our government?

"To be sure, the Orientals give more attention to this kind of mental training than do the Occidentals, and it is as a result of this peculiar training alone that they are able to accomplish the wonderful feats of telegraphing attributed to them. Of course there is a class of ignorant sceptics who brand a man accepting such a hypothesis as a spiritualist or a gullible convert to voudoo art, but ghosts and spooks and haunts, or whatever you choose to call them, have no bearing upon this question at all.

"It will take us perhaps years to learn this new art, but instruments for such practice and training have already been devised. Between them thoughts and intelligence can be transmitted without regard to distance and intervening matter by means of inconceivably minute and rapid ether waves. It is simply an extension of the well known natural law under which sound is conveyed by vibrations of the atmosphere and light is transmitted by those of the thinner ether.

Experiments of Interest.

"One of these instruments is a delicate little scale balance, somewhat like those for weighing letters. Instead of the flat stand for supporting the letters there is a disk covered with a thin membranous material. The recording pointer moves against a revolving cylinder of record paper and writes in a waved line such as is understood by scientists.

"Now, Sir William Crookes, the celebrated English chemist, carried on some experiments with this and proved to his satisfaction that the human mind exerted at a distance could will the disk to move up or down. The subject was only a few feet away, to be sure, but this was only the beginning. Why could not there be made an instrument with sufficient delicacy to catch every vibration of the brain, just as Marconi's 'coherer' catches his electric waves, likewise thrown out in ether?

"There are mechanical means for practice of concentration and relaxation, the one condition needed by the transmitter and the other by the receiver. One of the more interesting transmitting devices consists of an alphabet printed in huge black letters upon large circular disks of white cardboard, a black screen and a small projector for throwing light rays. A darkened room is essential to thorough concentration. Suppose you wish to transmit the message 'Come' to your receiver. You would take each letter at a time and hang it upon the centre of the black screen, within focus of the projector, which may be a very strong bull's-eye lamp throwing a circle of light like that of a stereopticon. The mind is concentrated upon each letter until all external consciousness is definitely eliminated.

"The receiver, wherever he may be, sits in a similarly darkened room, keeps his mind in a perfectly passive state and gazes blindly into space. Gradually there appears before his eyes a wavy cloud followed by a pale bluish light, very bright in the centre. As he continues to gaze, the letters impressed upon the mind of the transmitter focus themselves into view.

"Perhaps money will sometime buy the secrets of the wireless telegraphy of the Orientals, or perhaps we Occidentals shall ourselves become masters in an equal art of our own perfection. At any rate, the day is not infinitely distant when all such mechanical devices as employed by Marconi, Tesla and the other workers along the electric line, shall have become obsolete and corps of selected operators will transmit our military, commercial and social despatches with no other instruments than their own heads, and with no expense save that of their own gray matter."

Argument For the Fundamental Tesla Polyphase Patents.

During the past few weeks, argument has been heard by the U. S. Circuit Court for the District of Connecticut, at New Haven, in the case of the Westinghouse Electric & Manufacturing Company against the New England Granite Company, et al., for infringement of the Tesla polyphase patents, Nos. 381,968, 382,279 and 382,280, the first of these dating back to May 1, 1888. The defendant concern has been using a polyphase plant alleged to infringe these patents. For plaintiffs the case was argued by Messrs. F. H. Betts, L. E. Curtis, and T. B. Kerr, and for the defendant by Messrs. C. E. Mitchell and H. B. Brownell. The motor sued on is a Cushman supplied with current from a General Electric three-phase generator.

In his argument, Mr. Betts asserted that with the publication of Mr. Tesla of his invention before the American Institute of Electrical Engineers in May, 1888, and with the simultaneous grant of his patents, "a new thought, a new era of construction, and even a new department of electrical terminology" came into the world, and that these facts were at once admiringly conceded by electrical engineers everywhere. The expression of contemporaneous opinion as to the character of a step in an art has always been deemed by the courts, in patent cases, as of great significance (see the Telephone Case, 126 U. S., p. 1; New Process Fermentation Co. vs. Maus, 122 U. S., p. 413; Electric Accumulator Co. vs. Julien Co., 38 F. R., p. 132). Mr. Tesla had found existing systems of power generation and transmission inadequate for their work. Direct current was not available in large quantities for long distances and was cumbered by the use of a commutator. Single-phase alternating current had failed because of the troubles due to obtaining synchronism between generator and motor, and the art was virtually at a standstill, except in regard to the use of current in small areas or small quantities. This then, was the state of the art as Tesla found it. Alternating currents were the only long distance power currents anywhere generated. But alternating currents could not be used as such successfully, for transmission of power, or, in other words, in "motors," because the alternations for the effective transmission of power were too fast. The motor could not keep up with them. It might be brought up to synchronous speed and would continue to run as long as such synchronism was substantially maintained. If a load was put on the machine which impaired synchronism the motor stopped. Mr. Tesla set himself to work to reconcile contradictions and to overcome difficulties which had blocked the way of the use of alternating currents in their initial condition. In doing this he turned the difficulties into means of success.

His new conception was that alternating currents could be made a source of power, notwithstanding the rapidity of alternation, or rather by reason of the rapidity of their alteration of direction (for, other things being equal and within practical limits, the higher the rate of alternation, the higher the efficiency of the machine). He perceived that by combining two or more of such currents, displaced in period of arriving at each point in their cycle of changes, the rising potential of one would accompany the falling potential of the other, and their joint effect would be to produce between them a "resultant pole" (which was the result of the combination of the magnetism of both), which would be constantly and progressively shifting its position around a circle, and which thereby produced a "whirling field." This met every difficulty by creating a continuous force in one circular direction, which tends continuously to drag the armature after the point of greatest attraction in the "whirling field," and thereby produces a source of power which becomes more effective the more rapidly it whirled; that is, the more rapid the alternations in direction.

The whirling field produces a condition in the motor which will always tend to start the armature, and will, in fact, start it, if the armature be of proper construction, and will cause the armature to run faster and faster to endeavor to catch up with the swiftly whirling pole. In this way "power" is generated. A practical alternating current motor (i. e., something that would move something else) was made. A motor capable of carrying large loads at high speeds was produced, the efficiency depending, so far as the "whirling" field was concerned, upon the rapidity of alternations in the generator, and the starting capacity and mutual attraction between such field and the armature, depending upon the particular construction of the armature. This, then, is the gist of the Tesla method and apparatus for transmitting power.

The "method" consists of the generation and utilization of two or more alternating currents of different periodicity to produce in a motor having corresponding circuits, a whirling field, or source of power. The "apparatus" consists, essentially, of a motor having a plurality of circuits, in which alternating currents of differing phase are produced, without mingling or interfering with each other, combined with a generator of alternating currents of differing phase, connected to the motor by transmission conductors of such a character as to preserve the independence and proper succession of phases, and thereby produce the whirling field. The method of operation just described is fully set forth in the Tesla Patent No. 382,280. The primary patent for the apparatus is No. 381,968.

But Mr. Tesla, having laid his foundation, said Mr. Betts, made other and supplementary inventions, and one of these is embodied in the third patent, No. 382,279, in which an armature of great capacity for developing a condition of structural attraction between it and the field is described. The gist of this is the construction of the motor with an armature (or moving member) wound with "closed coils." The effect of these closed coils is that the attraction between the moving armature and the field is increased by any lagging behind in speed of the armature with reference to the "whirling field" of force. There are subordinate claims in Patent No. 381,968 and No. 382,279, for improvements in the form of construction of the field magnet in a multiphase alternating current apparatus. These claims are founded upon the superiority of the "annular" or "ring" type of field magnet in the apparatus of the multiphase type.

Mr. Betts went on to point out that the utility of the invention, as such, was never contested, and deprecated the defendant's contention that it was merely an "invention on paper." Mr. Tesla built such motors and showed them, and his system had come largely into use. Moreover, attacks upon the degree of utility of machines made in exact accordance with the drawings of a patent have been so often characterized by the courts as futile that there should be an end of such defences. The Supreme Court of the United States in the Bell Telephone Case swept away a far more vigorous contention of the contestants, because based upon the fact that Prof. Bell had never in fact utilized the exact instrument of his patent for the successful transmission of a single articulate word (126 U. S., 1.). In Loom Co. vs. Higgins, 105 U. S., 586, the court said: "When the question is whether a thing can be done or not it is always easy to find persons ready to show how not to do it." Judge Coxe, in the Mergenthaler Case, 57 F. R., p. 502, satisfactorily disposed of all such defences, and in the latter case of Rynear Co. vs. Evans, 83, F. R., p. 697, he sarcastically remarked that a judicial experience of many years had convinced him "that when an expert undertakes to prove that his adversary's process or machine is a failure he always scored a success."

Mr. Betts then discussed four publications which were assumed by the defendant to anticipate Tesla. The first of these was by Mr. W. Bailey, in 1879, on a mode of producing Arago's rotation. But Bailey made not the faintest suggestion of the use of two "alternating" currents of differing phase generated by an alternating-current generator, and used to produce a shifting of the magnetic field in a motor. Bailey's paper describes no phenomenon except the ordinary one always present in every direct-circuit machine, of intermittently shifting the attractive poles by the reversal of a straight current by means of a commutator. Tesla does not claim, of course, to have been the first to produce a progressive shifting of the poles of a motor by any and all means. What he describes and claims is the method of progressively shifting such poles by combining two true alternating currents of differing phase. In his paper of May, 1888, he distinctly states this.

The next publication was that of Deprez in December, 1883, and later. But all that he demonstrated as a mere theoretical abstraction was that, if a machine were made in which the field magnet varied in position with reference to the brushes, the variation would be indicated by the needle of another machine. The needle of another machine would move so that whenever the angle between the brushes of the first machine moved, it would stop and indicate on a scale, attached to the second machine, the new angle which was subtended between the brushes and magnet. The only practical application of this thought was to indicate upon a ship's compass the position of the magnetic pole with reference to the course of the ship. It was said by the expert for the defendants that if the machine described by Deprez, which was constructed with a magnet and brushes capable of changing their angle with reference to each other, had been so used as to rotate the brushes continuously, the machine would have produced currents, not only differing in period of maximum and minimum potential, but also alternating in direction at proper intervals.

But certainly Deprez did not describe this, and had not the remotest idea of utilizing either the alternations of direction or the rapidity of such alternations, or the progressive and regular sequence of cyclic changes produced by continuous alternations. The only suggestion which Deprez makes is that the theorem of the parallelogram of forces can be employed to produce an indicator of position. The idea of utilizing that law, as exemplified in a two-phase alternating-current machine as a source of power, never dawned upon his mind. In fact, he pronounced alternating currents to be useless for power purposes, and in his famous Paris to Creil experiments resorted to direct current.

Next came the Siemens and Von Alteneck English patent of 1878, but Mr. Betts contended that all that could be asserted of the Siemens patent was that, in the case of a single one of the machines the position and connection of coils is such that the machine would initially generate two alternating currents of differing phase, but the inventors do not mention this fact. Nor if they had it, would such distinguished inventors have allowed such a useful invention to slumber for ten years in oblivion. Moreover, every machine described was equipped with commutators to straighten out the current.

The last defence in the shape of publication was Bradley's application of 1887, culminating in a patent of October, 1888. It was claimed that only the application could be considered, and that most assuredly was only a thing on paper. But the Bradley application, even if it were competent by itself, presents nothing of material importance. True, it describes a generator which is capable of producing not only direct currents—by means of a "commutator"—but also one or more alternating currents, and there is a general statement near the end of the specification, that "It is obvious that my machine may be used as a motor as well as a generator, and that it may when so used be fed or actuated either by continuous or alternating currents or both." But this is very far from a statement that two or more alternating currents, as initially produced in a generator, are deliberately and intentionally not to be "commutated" or straightened, but, on the contrary, are to be conducted by proper circuits, which preserve their initial independence of phase, and then, without "commutation" are to be utilized in corresponding circuits of the motor. True, Bradley claims in his original third claim an "alternating current dynamo-electric machine with windings to produce currents of differing phase." But Siemens had described such a machine in 1878, and Bradley does not claim, and nowhere even suggests, the use of such a machine as a motor by means of uncommutated currents of different phase. So, in his fourth claim, he claims an "alternating current dynamo-electric machine" having its armature wound with a closed coil, and utilized by means of complete contact rings, and such contact devices as are shown. But he fails to point out anywhere in his specification, or suggest in his claim, the combination of such a generator with such a motor, by means of circuits which will preserve independence of generated phase and utilize the same, as such, in the motor.

Mr. Betts asserted that Bradley's application and description is too vague. He had no thought of utilizing the difference of phase as a source of power. This, he thought, is conclusively shown by the fact that the only specific description contained in his original application, in connection with the initial production of two phases, is accompanied by the description of the running together of such phases and the production of "one single alternating current" by combining the two currents "by induction" by means of a converter.

When Bradley came to patent his device, five months after Tesla's patent had been granted, he erased the figure illustrating the transformer for running together the two phases by induction, so as to produce "one single alternating current," and he struck out that part of his description. This action was significant and decisive against the contention that he had knowledge of, or described, any use of two-phase currents generated and propagated and utilized as such.

Coming to the broad question of infringement, Mr. Betts noted that the principal contention of the defendants was that they did not use the "independent" circuits of Tesla, and also that the interposition of converters for letting down the current was a differentiation. The latter point he dismissed as idle, Tesla's system

being devised for the very purpose of high potential transmission and low potential use. The contest hinged upon the meaning of "independent circuits." Mr. Betts argued that the language used in a patent is almost necessarily less than the idea. The invention is larger than the form in which it is expressed, and the courts have even gone so far in carrying out that rule—when an invention before them is of an important character, and is important and valuable because it is capable of being expressed and embodied in a great variety of forms—as to disregard the literal wording of the claims if the substance of the invention has really been appropriated by an infringer. Nothing can be more pertinent on that point than the ruling of the Supreme Court in Hoyt vs. Horne.

It was true that the defendants connect the circuits of their generator at one end to each other, and the circuits of their motor in delta form, and that they use three transmitting wires in place of the six which Tesla illustrates in his several figures. But, none the less, the circuits of their generator and transmission circuits and the motor circuits, act independently, in so far as they preserve and utilize independence of phase, precisely in the same way as do the isolated circuits used in Tesla's illustrations. Besides, the defendants did not invent the "three-wire" system of electrical transmission, nor the practice of utilizing, in independent circuit systems, such parts of connected circuits whose use did not interfere with the appropriate work of those portions of the circuit which were in fact separate. Mr. Betts cited the proposal of three wires, with phase difference of 120 degrees, for the Lauffen-Frankfort transmission in 1891, and pointed out that Tesla himself in his paper of May, 1888, said of the economy of wires in connection with the two-phase system, "Instead of using four wires with like result, three wires may be used, one forming a common return for both circuits." In other words, and, in short, "independence" did not mean "isolation," and it was the phases of potential or varying pressures that were to be kept separate from each other, not the "currents." The defendants admitted that the generator which supplies their motor system with energy generates three alternating currents of differing phase of potential—that is, the time of reaching maximum and minimum potential in the circuits is 120 degrees apart. The potential thus generated in the three circuits of the generator is transmitted with the "independence" of phase, and time relation thereof, unimpaired, to the motor, and such potential, acting in the circuits of the motor, generates in such circuits three alternating currents of differing phase 120 degrees apart, and such currents in the motor produce a whirling field of exactly the same character as would be produced if the wires were six in number, instead of three.

No one could tag an atom of water any more than they can tag a vibration of electricity, and assert that it is the same atom or the same vibration which generated the pressure initially, which also transmitted and utilized it finally. "Pressure," or "potential," is the vital thing, and, if potentials of three different phases be produced and transmitted independently and utilized in a motor, it is of no importance whether such pressure was transmitted through three pipes or three wires, or six pipes or wires. The statement that the electromotive forces "so cancel out," when opposing each other, that there is in each circuit nothing but a current differing in phase by 120 degrees from the current in other circuits, is easily illustrated by diagrams.

As to the patents in suit, No. 381,968, was in dispute as to claims 1 and 3, touching the use of the word "independent," and as to the employment of an annular or ring shaped field magnet as a unit, the core and the winding to be regarded as a whole. Patent No. 382,280 was a claim for the "method." Mr. Betts remarked that a method of operation may be patented as a distinct invention from the apparatus which operates thereby. In the Bell Telephone case, the claim was for both the method and apparatus. The apparatus described by Bell was entirely different from that of the defendants in the several suits, and there was no infringement of the claim, so far as it was a claim for an apparatus, but the Supreme Court sustained the claim for the method and held that defendant infringed. This could not have been if the two inventions were exactly the same. In 94 F. R., p. 868, Judge Shipman, in a case on another Tesla patent, relating to a modification of the same system as that of the patent in suit, ruled that a claim for the "method" of operation was not void as covering merely a mode of operation or function of certain machines.

Patent No. 382,279 was for a motor having closed coils or closed inducing circuits on its armature. Infringement was not denied as to the first and second claims, unless the word "independent" is given the restricted meaning which was held to be untenable.

Infringement of the third claim was denied on the ground that the defendants' magnet is not "an annular field magnet," but this was due to the misapprehension of the meaning of the phrase, as noted above.

Mr. Betts touched last upon the decision of the Imperial Court of Germany, under which Tesla had been compelled to erase his broader claims and take refuge in limited phraseology. With regard to this, Tesla, admitting that the invention had not been "worked," in a strict sense, sought to have his default excused, on the ground that he had offered to license some one, and that infringers had adopted his method and claims by utilizing what is termed the "rotary current system," with three conductors instead of six. The court held that, in view of the limitations of his patents, and in view of the striking out of his claims as first presented, and in view of the substitution of narrow ones, and in view of the fact that certain explanatory language, as to what was meant by "independent" circuits, having been originally in the specifications, but stricken out, they would not give to the patents the broad construction which would enable Tesla to save them by relying upon the work of infringers as a statutory "working" of his invention. The German court went on to say that, even if the explanatory sentences had been left in, they would, nevertheless, have come to the same conclusion. But this was obviously a mere obiter dictum. No such question was before the United States Court, as the sentences had, in fact, been erased before the patent was issued.

But a more important fact came up in the German case, namely, the Ferraris publication in April, 1888, at Turin, of analogous ideas. This pamphlet had been distributed abroad, and was therefore part of the prior art there, and the German patents of Tesla could only be valid if at all, for specific construction. But the Ferraris lecture had no place in the prior art in the United States, and had not been invoked here by the defendants. "Here," concluded Mr. Betts, "Tesla is a primary inventor, being the actual originator of a new method of electrical transmission of power, which has revolutionized industry."

NOTES ON LIGHT.

BY WILLIAM ROLLINS.

NOTE LXXVIII—HYDROGEN IN TESLA-LIGHT TUBES.

Tesla, the father of vacuum-tube lighting, has said the higher the vacuum the better the light. This is an important fact in a system which is to be a light of the future. A second is this: The vacuum should be hydrogen and adjustable. This obvious deduction from what I have shown about this gas and X-light is mentioned now rather than later, when I shall describe experiments with Tesla light, because I should not like to see the idea patented for those of us "who serve the dream" know them unwise.

NOTE LXXIX—CHEMICAL HYDROGEN REGULATORS OF CHEAP X-LIGHT TUBES.

It is possible to buy an X-light tube for $5, which leaves the makers so small a profit they have to reduce the platinum to the lowest. They are, therefore, unable to use my intermolecular regulators of platinum or palladium, and either have none or the ordinary potash or the oxygen bulb, the life of these tubes is in consequence very short as they die of cathode exhaustion. I gave my tube-makers two years ago a formula for a chemical regulator which liberated hydrogen, but as their work is chiefly in furnishing the finest tubes to hospitals they have little use for it. I now publish the method, as it is worthy of extended use in connection with low-cost tubes, as it increases their price only five cents. I have shown in other notes that X-light was a hydrogen phenomenon for practical purposes and that in consequence it was necessary to introduce this gas. What therefore is necessary to revive cheap tubes is to have some chemical in a small supplementary bulb which will liberate hydrogen at a temperature low enough so the glass bulb will not soften in the process.

Sodium formate will do this.

NOTE LXXX—SUPPORTING THE STEMS OF X-LIGHT TUBES.

In Note lxi, it was said that the universally-used glass wrappings about the stems of the terminals in a vacuum tube were not only unnecessary but undesirable. In Fig. 56 a tube was shown with strong, bare stems supported by diaphragms blown in the glass. As I aim to make a tube which will be easy to construct, as well as durable, graceful and efficient, this kind of support has been abandoned, for it took a good workman to make it, and sometimes the glass would crack at the seal. The stems are now supported by collars of mica, or what may prove better, by rings of molded lava, as suggested by Mr. Heinze. This construction applied to my rotary and cooled target tubes is shown in Figs. 64 and 65, and in detail in Figs. 66 and 67. In these illustrations the electrolytic regulators are shown forming the support for the cathode stems, thus doing away with one piece of platinum wire. I have used this position for the platinum heat regulator for a long time, but, on account of the length of the platinum, it has been criticised as making the vacuum tube more liable to injury than when the regulator is placed on the side. The electrolytic regulator is now so short that this objection is without force. Fig. 68 shows the details of such a regulator.

TESLA IS NOT SICK

And He Says He is Going to Telegraph from New York to Paris Without Wires.

DENVER, Col., Jan. 14.—Nikola Tesla proposes to telegraph from New York to Paris without wires. He arrived yesterday from Colorado Springs, where he has been working secretly, and announced that he had perfected a system of wireless telegraphy vastly superior to that of Marconi. He left for New York last night.

Said Mr. Tesla: "I didn't come to Colorado for my health, but to learn the effect of dry air and high altitude upon the machine I have perfected. The benefits of my machine during a sea fight cannot be estimated. It will aid in doing deadly work.

"The beauty of my machine is that it can transmit power over several thousands of miles without wires. Now the Marconi system is useless at distances of more than one hundred miles. Any operator can read a message in transit by the Marconi system. It is impossible to do this with my machine. I expect to send messages to Paris during the Fair."

A SPECIAL cable dispatch to the N. Y. "Sun" from London states that the Secretary of the Wireless Telegraphy Company says that Inventor Marconi will make extensive tests in England in 1900 in behalf of the United States Government, with which negotiations are merely in abeyance. Marconi thinks that the present limit of eighty-six miles in communication will shortly be raised to 150 miles. He has no belief in Nicola Tesla's promise to communicate across the Atlantic. He believes that science, while gradually progressing, will be unable to obtain such great results before the preliminary difficulties have been surmounted. Personally, he does not expect, yet, to girdle the Atlantic. Meanwhile, the "Daily News" reports that Emilion Guarini, a native of Puglia, Italy, who is little more than 20 years of age, has discovered a means of utilizing Marconi's invention at the greatest distances. He accomplishes this by means of his own invention, which is called a repeater and which he says receives the electric waves and is capable of transmitting them to other repeaters for continuous repetition. He says he needs a repeater only at every five-hundredth mile. He further claims that his invention will enable polar expeditions to keep in constant communication with civilization.

WE announced some time ago that NIKOLA TESLA had gone to the top of a high mountain in Colorado to experiment not only in wireless telegraphy, but also in the wireless transmis sion of energy over a long distance. He has now returned to New York evidently well pleased with the result of his experiments, and the following remarks of his to a New York reporter convey his views and anticipations as to future developments :—

My experiments have been most successful, and I am now convinced that I shall be able to communicate by means of wireless telegraphy not only with Paris during the Exhibition, but in a very short time with every city in the world. My terminal instruments will be absolutely immune from extraneous disturbances, and I hope to obtain a speed of from 1,500 to 2,000 words a minute. I have returned to New York to pursue a series of experiments with a view to solving the greater problem of transmitting power without using wires.

Personal.

NIKOLA TESLA says he will remove his laboratory from New York City to Colorado Springs, Colo., and there make his permanent residence. This time he "has perfected a machine by which he can transmit power several thousand miles without wires." N. T. is a good thing for the "science" supplements of the Sunday papers.

Queries and Answers

What are the dimensions of the core, size of wire and number of turns for a Tesla coil to work with a 6-inch induction coil? What means may be used for regulating the same when supplied with alternating current?

S, J. S.

Tesla coils have no cores and must be very highly insulated. One of the easiest ways of making one is to take a large cylindrical battery jar 8 inches in diameter by 12 inches long, and wind over it about 60 or 80 turns of No. 18 magnet wire. This may then be fixed to the jar by a coating of shellac. The primary should be made of 8 or 10 turns of No. 4 or No. 6 wire, made sufficiently small to slip inside the jar. The whole should be enclosed in a big earthenware tub and filled with mineral seal, linseed or transil oil. For regulation the ordinary means of choking back the current in the primary of the induction coil may be used.

CONTEMPORARY CELEBRITIES

Nikola Tesla

Tesla has seemed to be under a cloud of late, but in the Philadelphia North American he is brought out once more, with his characteristics as a man, by Julian Hawthorne:

Tesla, the papers say, has left his eyrie on the flank of Pike's Peak in Colorado, and is on his way East with a new wireless telegraphy invention in his pocket. It is hard to realize how much the contents of this man's mind may mean for the world. I met him a few years ago in a famous but now obsolete cafe, near Madison Square, in New York, and we dined together there. I saw a tall, slender young man, with long arms and fingers, whose rather languid movements veiled extraordinary muscular power. His face was oval, broad at the temples and strong at the lips and chin; with long eyes, whose lids were seldom fully lifted, as if he were in a waking dream, seeing visions which were not revealed to the generality. He had a slow smile, as if awakening to actualities, and finding a humorous quality in them. Withal, he manifested a courtesy and amiability which were almost feminine, and beneath all were the simplicity and integrity of a child. Tesla is, I believe, a Herzegovinian. The Greek type prevails in him. He has abundant wavy brown hair, blue eyes and a fair skin. He was a trifle shy at first; or perhaps it was merely that he did not at once arrive from the regions in which his mind is wont to reside, and adjust himself to the requirements of his actual environment. But his social instincts were of the royal order; as the host of the occasion, he wished that his guest should be entertained as became the hospitality of princes. There was a reminiscence of the Oriental about it; and if the scene had been a tent in the desert, one would soon have imagined it a palace. But oh, how far it was from the oppressiveness which renders some of the best-intended courtesies a burden! To be with Tesla is to enter a domain of freedom even more free than solitude, because the horizon enlarges so. His mind cast out genial rays that illuminated distances, and made the great and marvelous seem near and beautifully familiar. You have felt the power of good music to make you seem more than yourself; and similar was the influence of this ingenuous but profound student. My own deficiency in the technicalities of science seemed to offer no impediment to our intercourse; partly because, like other men of really sound attainments, he was easily able to make intelligible to my untrained comprehension the spiritual essence of his own speculations and discoveries; and partly because he turned out to be quite as much at home in my own little specialties as I was. He knew all English poetry, much of it by heart; nor was he less familiar with the literature of Germany and France, not to speak of more recondite branches of literary culture in which I was not proficient. He knew the art of ancient and modern times, and had thoughts on the subject that were not merely critical, but creative. With music he stood on the terms of a musician; and one can imagine the kind of transcendental symphony that a mind of his calibre and sympathies might compose. Meanwhile, he was one of the first, if not the foremost, scientific investigators of his epoch, which is the most scientific in human history; and when it was question of the vintage of a wine, or the condition and cooking of an ortolan, he knew that, too, though his own eating and drinking were of the most abstemious order. The total impression which I derived from his manifestations was not, however, of an intelligence divided off into chambers, from one or another of which the treasures were brought forth as needed; but it seemed to be always the same entire and perfect chrysolite of intellectual ability, directed this way or that, focused far or near, as occasion served. Naturally it was toward the possibilities of the future in the way of ascertaining and controlling natural laws that I was most solicitous to direct the conversation. Tesla is the most modest of men, but also one of the most generously communicative when his confidence is secured; and I drew from him the wonderful story of his early experiences, his student days in a great European university—which I will not repeat here, not being authorized to do so. Then he went on to outline the nature and expected outcome of some of his dealings with electricity and other obscure forces of nature. As he spoke, mankind seemed to arise a Titan, and grasp the secrets of the skies. I saw a coming time when the race would no longer be forced to labor for the means of livelihood, when the terms rich and poor would no longer mean difference of material condition, but of spiritual capacity and ambition; a time when intercommunication all over the earth should be immediate and universal, and even when knowledge should be derived from sources now hardly imagined.

[97683.]—Tesla Coil.—The use of the oil is to insure good insulation. Even if a leak momentarily occurs in the coil, the oil oozes in and restores the insulation. The object of the jar is to increase the number of oscillations or "frequency" of the currents.

S. BOTTONE.

The New York Herald March 9, 1900

TESLA HAS NARROW ESCAPE.

Fire did $3,000 damage yesterday in the cellar of the seven story building Nos. 46 and 48 East Houston street. Nikola Tesla occupies three floors in the building. Five years ago his laboratory in West Broadway was destroyed by fire. The firemen said that if yesterday's blaze had not been promptly discovered Tesla probably would have been burned out a second time.

MR. TESLA'S LABORATORY IN DANGER.—One day last week the building on East Houston Street, New York, in which Mr. Nikola Tesla has his laboratory, was damaged by fire. The flames, however, were confined to the basement and did not reach Mr. Tesla's quarters. It will be remembered that Mr. Tesla's laboratory on South Fifth Avenue was burned out a few years ago.

A TESLA PATENT.—A patent issued March 20 to Nikola Tesla relates to the production at one point of an electrical pressure of such character and magnitude as to cause thereby a current to traverse elevated strata of the air between the point of generation and a distant point at which the energy is to be received and utilized. As illustrated, the apparatus consists of a generator supplying current to the primary of a transformer; the secondary consists of many turns and is connected at one side to the earth and at the other side to a terminal of large surface, maintained by such means as a balloon at a high elevation. The receiver duplicates this apparatus, except that instead of a generator being in one circuit of the transformer, receiving devices such as lamps and motors take its place. The transformer consists of a coil of very large diameter wound in spiral form, either with or without a magnetic core. The inventor claims that this furnishes a practical method or system of transmission of energy through natural media without the use of wires.

The Wireless Transmission System for electric energy which Mr. Nikola Tesla has been working out for such a long time has been covered by a patent granted to him recently, although the application was filed more than three years ago. Its general scheme is indicated by the ninth claim, which reads: "The method of transmitting electrical energy through the natural media, which consists in generating current impulses of relatively-low electromotive force at a generating-station, utilizing such impulses to energize the primary of a transformer, generating by means of such primary circuit impulses in a secondary surrounded by the primary and connected to the earth and to an elevated terminal, of sufficiently-high electromotive force to render elevated air strata conducting, causing thereby impulses to be propagated through the air strata, collecting or receiving the energy of such impulses, at a point distant from the generating-station, by means of a receiving-circuit connected to the earth and to an elevated terminal, and utilizing the energy so received to energize a secondary circuit of low potential surrounding the receiving-circuit."

Tesla Telegraphy.—As the outcome of Mr. Nikola Tesla's experiments on wireless telegraphy at high altitudes a patent has recently been issued to him in America, which is briefly summarised in the *Electrical World* as follows: "The patent relates to the production at one point of an electrical pressure of such character and magnitude as to cause thereby a current to traverse elevated strata of the air between the point of generation and a distant point at which the energy is to be received and utilised. As illustrated, the apparatus consists of a generator supplying current to the primary of a transformer; the secondary consists of many turns, and is connected at one side to the earth and at the other side to a terminal of large surface, maintained by such means as a balloon at a high elevation. The receiver duplicates this apparatus, except that instead of a generator being in one circuit of the transformer, receiving devices such as lamps and motors take its place. The transformer consists of a coil of very large diameter wound in spiral form, either with or without a magnetic core. The inventor claims that this furnishes a practical method or system of transmission of energy through natural media without the use of wires."

Wireless Electrical Transmission.—As is well known, Mr. Nikola Tesla has been giving much attention and time lately to the problem of transmitting electric energy between distant points through the air. A patent was issued in the United States to that gentleman on March 20th, which relates to the production at one point of an electrical pressure of such character and magnitude as to cause thereby a current to traverse elevated strata of the air between the point of generation and a distant point at which the energy is to be received and utilised. As illustrated, the apparatus consists of a generator supplying current to the primary of a transformer: the secondary consists of many turns, and is connected at one side to the earth and at the other side to a terminal of large surface maintained by such means as a balloon at a high elevation. The receiver duplicates this apparatus, except that instead of a generator being in one circuit of the transformer, receiving devices such as lamps and motors take its place. The transformer consists of a coil of very large diameter wound in spiral form, either with or without magnetic core. The inventor claims that this furnishes a practical method or system of transmission of energy through natural media without the use of wires.

Nikola Tesla Power Transmission. — Another patent by Mr. Nikola Tesla for the electric transmission of power by means of the upper strata of the atmosphere has now been published in America. The inventor proposes to use balloons to lift his sending and receiving conductors, and to employ such high electric pressures as millions of volts with a frequency of several thousand per second. The earth is to be used as a return, but we are not quite clear how the inventor will be able to prevent earth troubles with his return. In the patent the experimental apparatus is described for generating E.M.F.'s of from two to four million volts, and it is stated that current from such a machine can be sent through a glass tube 50ft. long with a barometric pressure of from one-third to one-fifth of an atmosphere. The estimated height of the captive balloons is put at from four to seven miles above sea-level, and Mr. Nikola Tesla proceeds to claim broadly the propagation of electrical energy by conduction through earth and air. The theoretical difficulties, let alone the practical difficulties, are so great in connection with this proposed scheme, that we do not propose to criticise it further until some actual results of experiments are published.

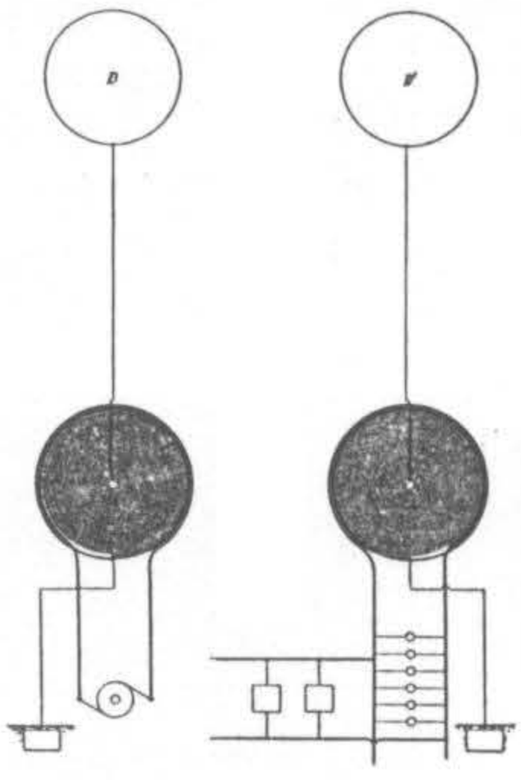
dition of the atmosphere, and also by the character of the surrounding country. The aerial conductors to these terminals are connected to the secondary of a spiral coil, the other end of the coil being connected to earth.

It is stated that the length of the thin wire in each of these coils should be approximately one-quarter of the wave length of the electric disturbance in the circuit, this estimate being based on the velocity of the propagation of the disturbance through the coil itself and the circuit with which it is to be used. For example, if the rate at which the current traverses the circuit including the coil be 185,000 miles per second, then the frequency of 925 miles per second would maintain 925 "stationary moves" in a circuit of 185 miles long, and each wave would be 200 miles in length. For such a low frequency, a secondary 50 miles in length would be used.

As will be noted from the illustration, the primary of the transmitting coil is supplied with a current by a dynamo, and the large coil of the receiver is connected with a circuit including lamps and motors. It is stated that the phenomenon involved in the apparatus is one of true conductions and not to be confounded with the phenomena of electrical radiation which have heretofore been observed, and which from the very nature and mode of propagation will render practically impossible the transmission of any appreciable amount of energy to such distances as are of practical importance. The specification states that if the potential is sufficiently high and the terminals of the coil be maintained at the proper elevation where the atmosphere is rarefied, the stratum of air will serve as a conducting medium for the current produced, and the latter will be transmitted through the air "with, it may be, even less resistance than through an ordinary conductor."

A Tesla Patent.

The accompanying illustration is reproduced from a patent granted May 15 to a Nikola Tesla on an "apparatus for transmission of electrical energy." *D D'* are terminals of large surface maintained by such means as a balloon at a high elevation, the elevation depending upon the amount and quality of the work to be preformed, the con-



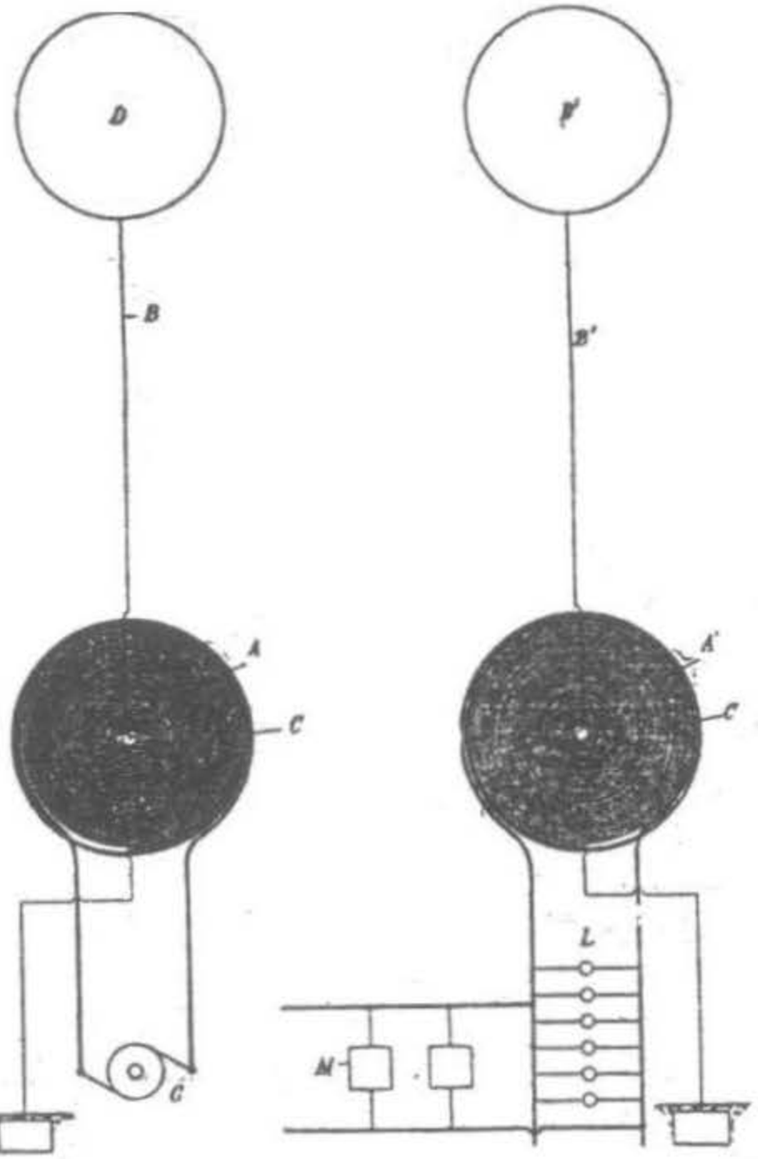


DIAGRAM OF TESLA APPARATUS.

APPARATUS FOR TRANSMISSION OF ELECTRICAL ENERGY.—No. 649,621; N. Tesla, New York, N. Y.

Combination with transmitting instrument comprising electrical transformer having its secondary connected to ground and to an elevated terminal respectively, and means for impressing electrica oscillations upon its primary, of receiving instrument comprising transformer having its primary similarly connected to ground and to an elevated terminal, and a translating device connected with its secondary, capacity and inductance of secondary of transmitting and primary of receiving intruments having such values as to secure synchronism with impessed oscillations.

MR. NIKOLA TESLA'S RECENT ELECTRICAL EXPERIMENTS.

A REMARKABLE paper, by Mr. Nikola Tesla, appears in the June number of the *Century Magazine*. The subject is "The Problem of Increasing Human Energy, with Special Reference to the Harnessing of the Sun's Energy"; and though metaphysical and sociological questions receive a large share of attention, the article contains an account of some very interesting electrical experiments, now described for the first time, illustrated by several very striking photographs, two of which are here reproduced. Mr. Tesla has been engaged for several years in further investigating the properties of alternate currents of high potential and frequency, with which he astonished audiences at the Royal Institution in 1892 (see NATURE, vol. xlv. p. 345). The following abstract of a part of his paper shows that his work has led to results of scientific interest and significance.

Electrical discharges capable of making atmospheric nitrogen combine with oxygen have recently been produced. Experiments made since 1891 showed that the chemical activity

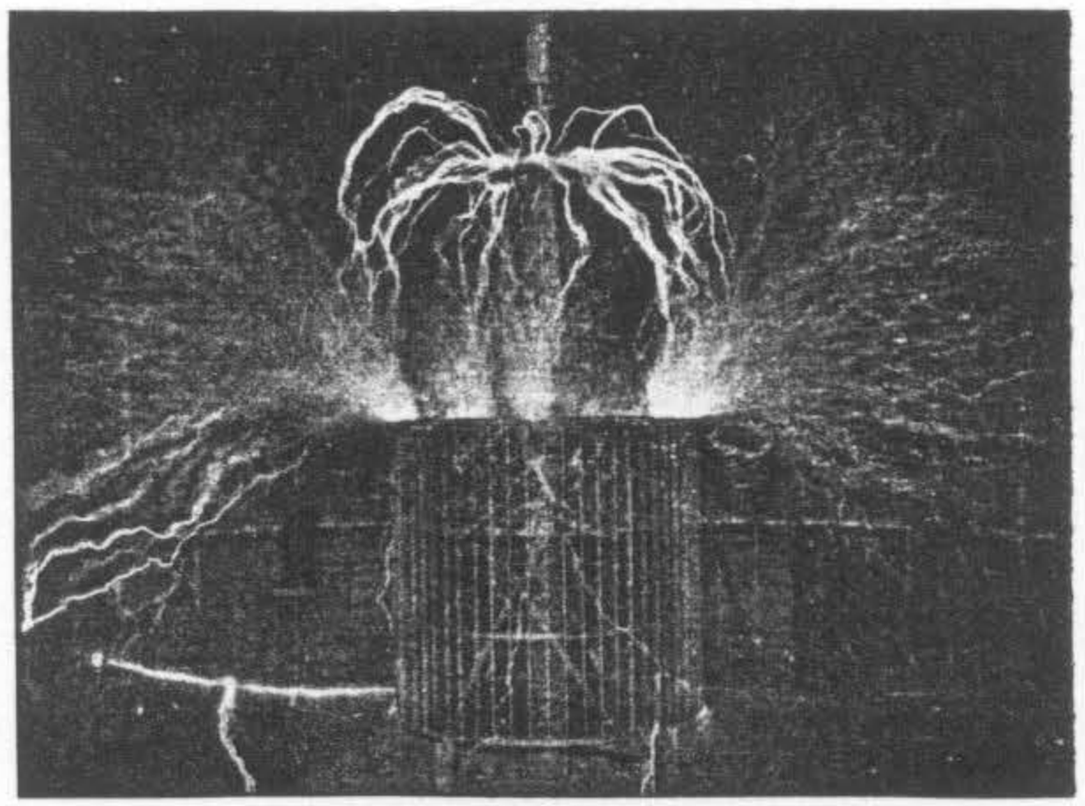

FIG. 1.—Combustion of atmospheric nitrogen by the discharge of an electrical oscillator giving twelve million volts and alternating 100,000 times per second. The flame-like discharge shown in the photograph measured 65 feet across.

of the electrical discharge was very considerably increased by using currents of extremely high frequency or rate of vibration. This was an important improvement, but practical considerations soon set a definite limit to the progress in this direction. Next, the effects of the electrical pressure of the current impulses, of their wave-form and other characteristic features, were investigated. Then the influence of the atmospheric pressure and temperature and of the presence of water and other bodies was studied, and thus the best conditions for causing the most intense chemical action of the discharge and securing the highest efficiency of the process were gradually ascertained. The flame grew larger and larger, and its oxidising action more and more intense. From an insignificant brush-discharge a few inches long it developed into a marvellous electrical phenomenon, a roaring blaze, devouring the nitrogen of the atmosphere and measuring sixty or seventy feet across (Fig. 1). The flame-like discharge visible is produced by the

intense electrical oscillations which pass through the coil shown, and violently agitate the electrified molecules of the air. By this means a strong affinity is created between the two normally indifferent constituents of the atmosphere, and they combine readily, even if no further provision is made for intensifying the chemical action of the discharge.

Under certain conditions the atmosphere, which is normally a high insulator, assumes conducting properties, and so becomes capable of conveying any amount of electrical energy. The discovery of the conducting properties of the air, though unexpected, was only a natural result of experiments in a special field carried on for some years previously. It was during 1889 that certain possibilities, offered by extremely rapid electrical oscillations, led to the design of a number of special machines adapted for their investigation. One of the earliest observations made with these new machines was that electrical oscillations of an extremely high rate act in an extraordinary manner upon the human organism. Thus, for instance, powerful electrical discharges of several hundred thousand volts, which at that time were considered absolutely deadly, could be passed through the body without inconvenience or hurtful consequences. Another observation was that by means of such oscillations light could be produced in a novel and more economical manner, which promised to lead to an ideal system of electric illumination by vacuum-tubes, dispensing with the necessity of renewal of lamps or incandescent filaments, and possibly also with the use of wires in the interior of buildings.

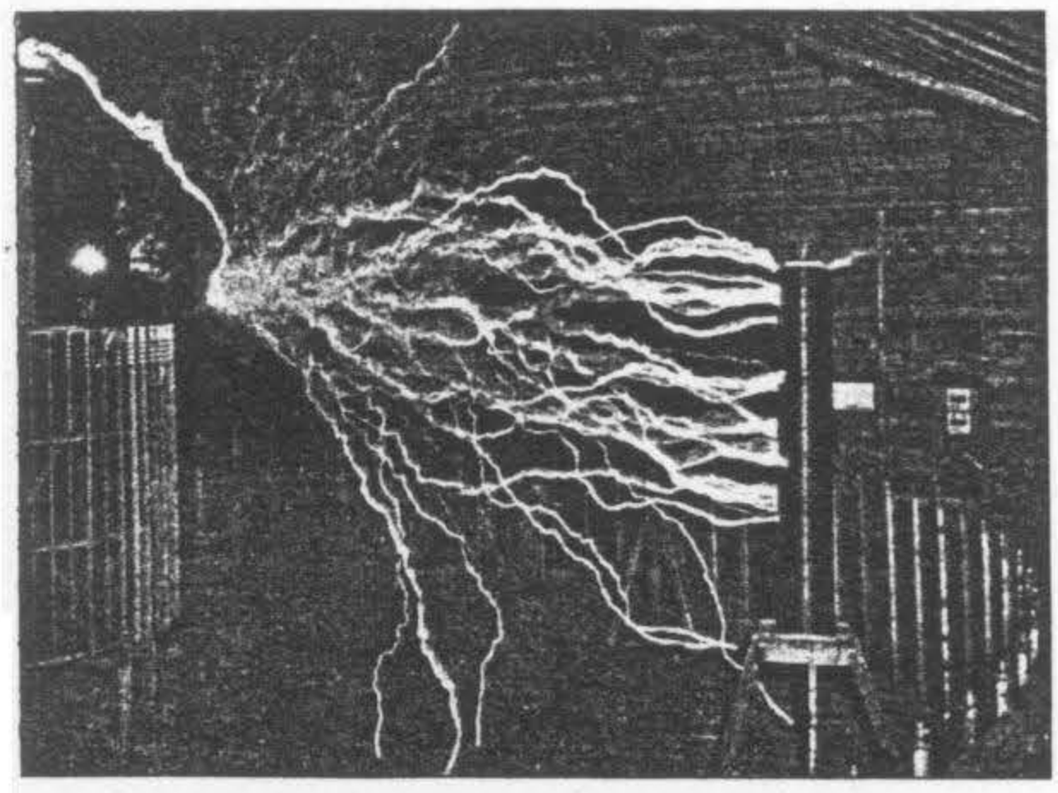

FIG. 2.—The coil, partly shown in the photograph, creates an alternating current of electricity at the rate of 100,000 alternations per second. The discharge escapes with a deafening noise, striking an unconnected coil 22 feet away, and creating such an electrical disturbance that sparks an inch long can be drawn from a water-main at a distance of 300 feet from the laboratory.

The investigations led to other valuable observations and results, one of the more important of which was the demonstration of the practicability of supplying electrical energy through one wire without return. To what a degree the appliances have been perfected since the demonstrations in 1892, when the apparatus was barely capable of lighting one lamp, will appear from the fact that as many as four or five hundred lamps have been lighted in this manner.

The success of this method of transmission suggested that the earth could be used as a conductor, thus dispensing with wires. The earth was regarded as an immense reservoir of electricity, which could be disturbed effectively by a properly designed electrical machine. Accordingly efforts were directed toward perfecting a special apparatus which would be highly effective in creating a disturbance of electricity in the earth, and a novel kind of transformer or induction-coil, particularly suited for this special purpose, was designed. By means of this apparatus, it is practicable, not only to transmit minute amounts of electrical energy for operating delicate electrical devices, but also electrical energy in appreciable quantities.

However extraordinary the results exemplified by Fig. 2 may appear, they are but trifling compared with those which are attainable by apparatus designed on these same principles. Electrical discharges have been produced, the actual path of which, from end to end, was probably more than one hundred feet long; but it would not be difficult to reach lengths one hundred times as great. Electrical movements occurring at the rate of approximately one hundred thousand horse-power have been obtained, but rates of one, five, or ten million horse-power are easily practicable.

The most valuable observation made in the course of these investigations was the extraordinary behaviour of the atmosphere toward electric impulses of excessive electromotive force. The experiments showed that the air at the ordinary pressure became distinctly conducting, and this opened up the wonderful prospect of transmitting large amounts of electrical energy for industrial purposes to great distances without wires, a possibility which, up to that time, was thought of only as a scientific dream. Further investigation revealed the important fact that the conductivity imparted to the air by these electrical impulses of many millions of volts increased very rapidly with the degree of rarefaction, so that air strata at very moderate altitudes, which are easily accessible, offer, to all experimental evidence, a perfect conducting path, better than a copper wire, for currents of this character.

The experiments have indicated that, with two terminals maintained at an elevation of not more than thirty thousand to thirty-five thousand feet above sea-level, and with an electrical pressure of fifteen to twenty million volts, the energy of thousands of horse-power can be transmitted over distances which may be hundreds and, if necessary, thousands of miles. Investigations are now being carried on with the object of reducing considerably the height of the terminals now required.

The Century Magazine June 1900

THE PROBLEM OF INCREASING HUMAN ENERGY.

WITH SPECIAL REFERENCE TO THE HARNESSING OF THE SUN'S ENERGY.

BY NIKOLA TESLA.

ILLUSTRATED BY THE WRITER'S ELECTRICAL EXPERIMENTS, NOW FIRST PUBLISHED.

THE ONWARD MOVEMENT OF MAN—THE ENERGY OF THE MOVEMENT—THE THREE WAYS OF INCREASING HUMAN ENERGY.

OF all the endless variety of phenomena which nature presents to our senses, there is none that fills our minds with greater wonder than that inconceivably complex movement which, in its entirety, we designate as human life. Its mysterious origin is veiled in the forever impenetrable mist of the past, its character is rendered incomprehensible by its infinite intricacy, and its destination is hidden in the unfathomable depths of the future. Whence does it come? What is it? Whither does it tend? are the great questions which the sages of all times have endeavored to answer.

Modern science says: The sun is the past, the earth is the present, the moon is the future. From an incandescent mass we have originated, and into a frozen mass we shall turn. Merciless is the law of nature, and rapidly and irresistibly we are drawn to our doom. Lord Kelvin, in his profound meditations, allows us only a short span of life, something like six million years, after which time the sun's bright light will have ceased to shine, and its life-giving heat will have ebbed away, and our own earth will be a lump of ice, hurrying on through the eternal night. But do not let us despair. There will still be left on it a glimmering spark of life, and there will be a chance to kindle a new fire on some distant star. This wonderful possibility seems, indeed, to exist, judging from Professor Dewar's beautiful experiments with liquid air, which show that germs of organic life are not destroyed by cold, no matter how intense; consequently they may be transmitted through the interstellar space. Meanwhile the cheering lights of science and art, ever increasing in intensity, illuminate our path, and the marvels they disclose, and the enjoyments they offer, make us measurably forgetful of the gloomy future.

Though we may never be able to comprehend human life, we know certainly that it is a movement, of whatever nature it be. The existence of a movement unavoidably implies a body which is being moved and a force which is moving it. Hence, wherever there is life, there is a mass moved by a force. All mass possesses inertia, all force tends to persist. Owing to this universal property and condition, a body, be it at rest or in motion, tends to remain in the same state, and a force, manifesting itself anywhere and through whatever cause, produces an equivalent opposing force, and as an absolute necessity of this it follows that every movement in nature must be rhythmical. Long ago this simple truth was clearly pointed out by Herbert Spencer, who arrived at it through a somewhat different process of reasoning. It is borne out in everything we perceive—in the movement of a planet, in the surging and ebbing of the tide, in the reverberations of the air, the swinging of a pendulum, the oscillations of an electric current, and in the infinitely varied phenomena of organic life. Does not the whole of human life attest it? Birth, growth, old age, and death of an individual, family, race, or nation, what is it all but a rhythm? All life-manifestation, then, even in its most intricate form, as exemplified in man, however involved and inscrutable, is only a movement, to which the same general laws of movement which govern throughout the physical universe must be applicable.

When we speak of man, we have a conception of humanity as a whole, and before applying scientific methods to the investigation of his movement, we must accept this as a physical fact. But can any one doubt to-day that all the millions of individuals and all the innumerable types and characters constitute an entity, a unit? Though free to

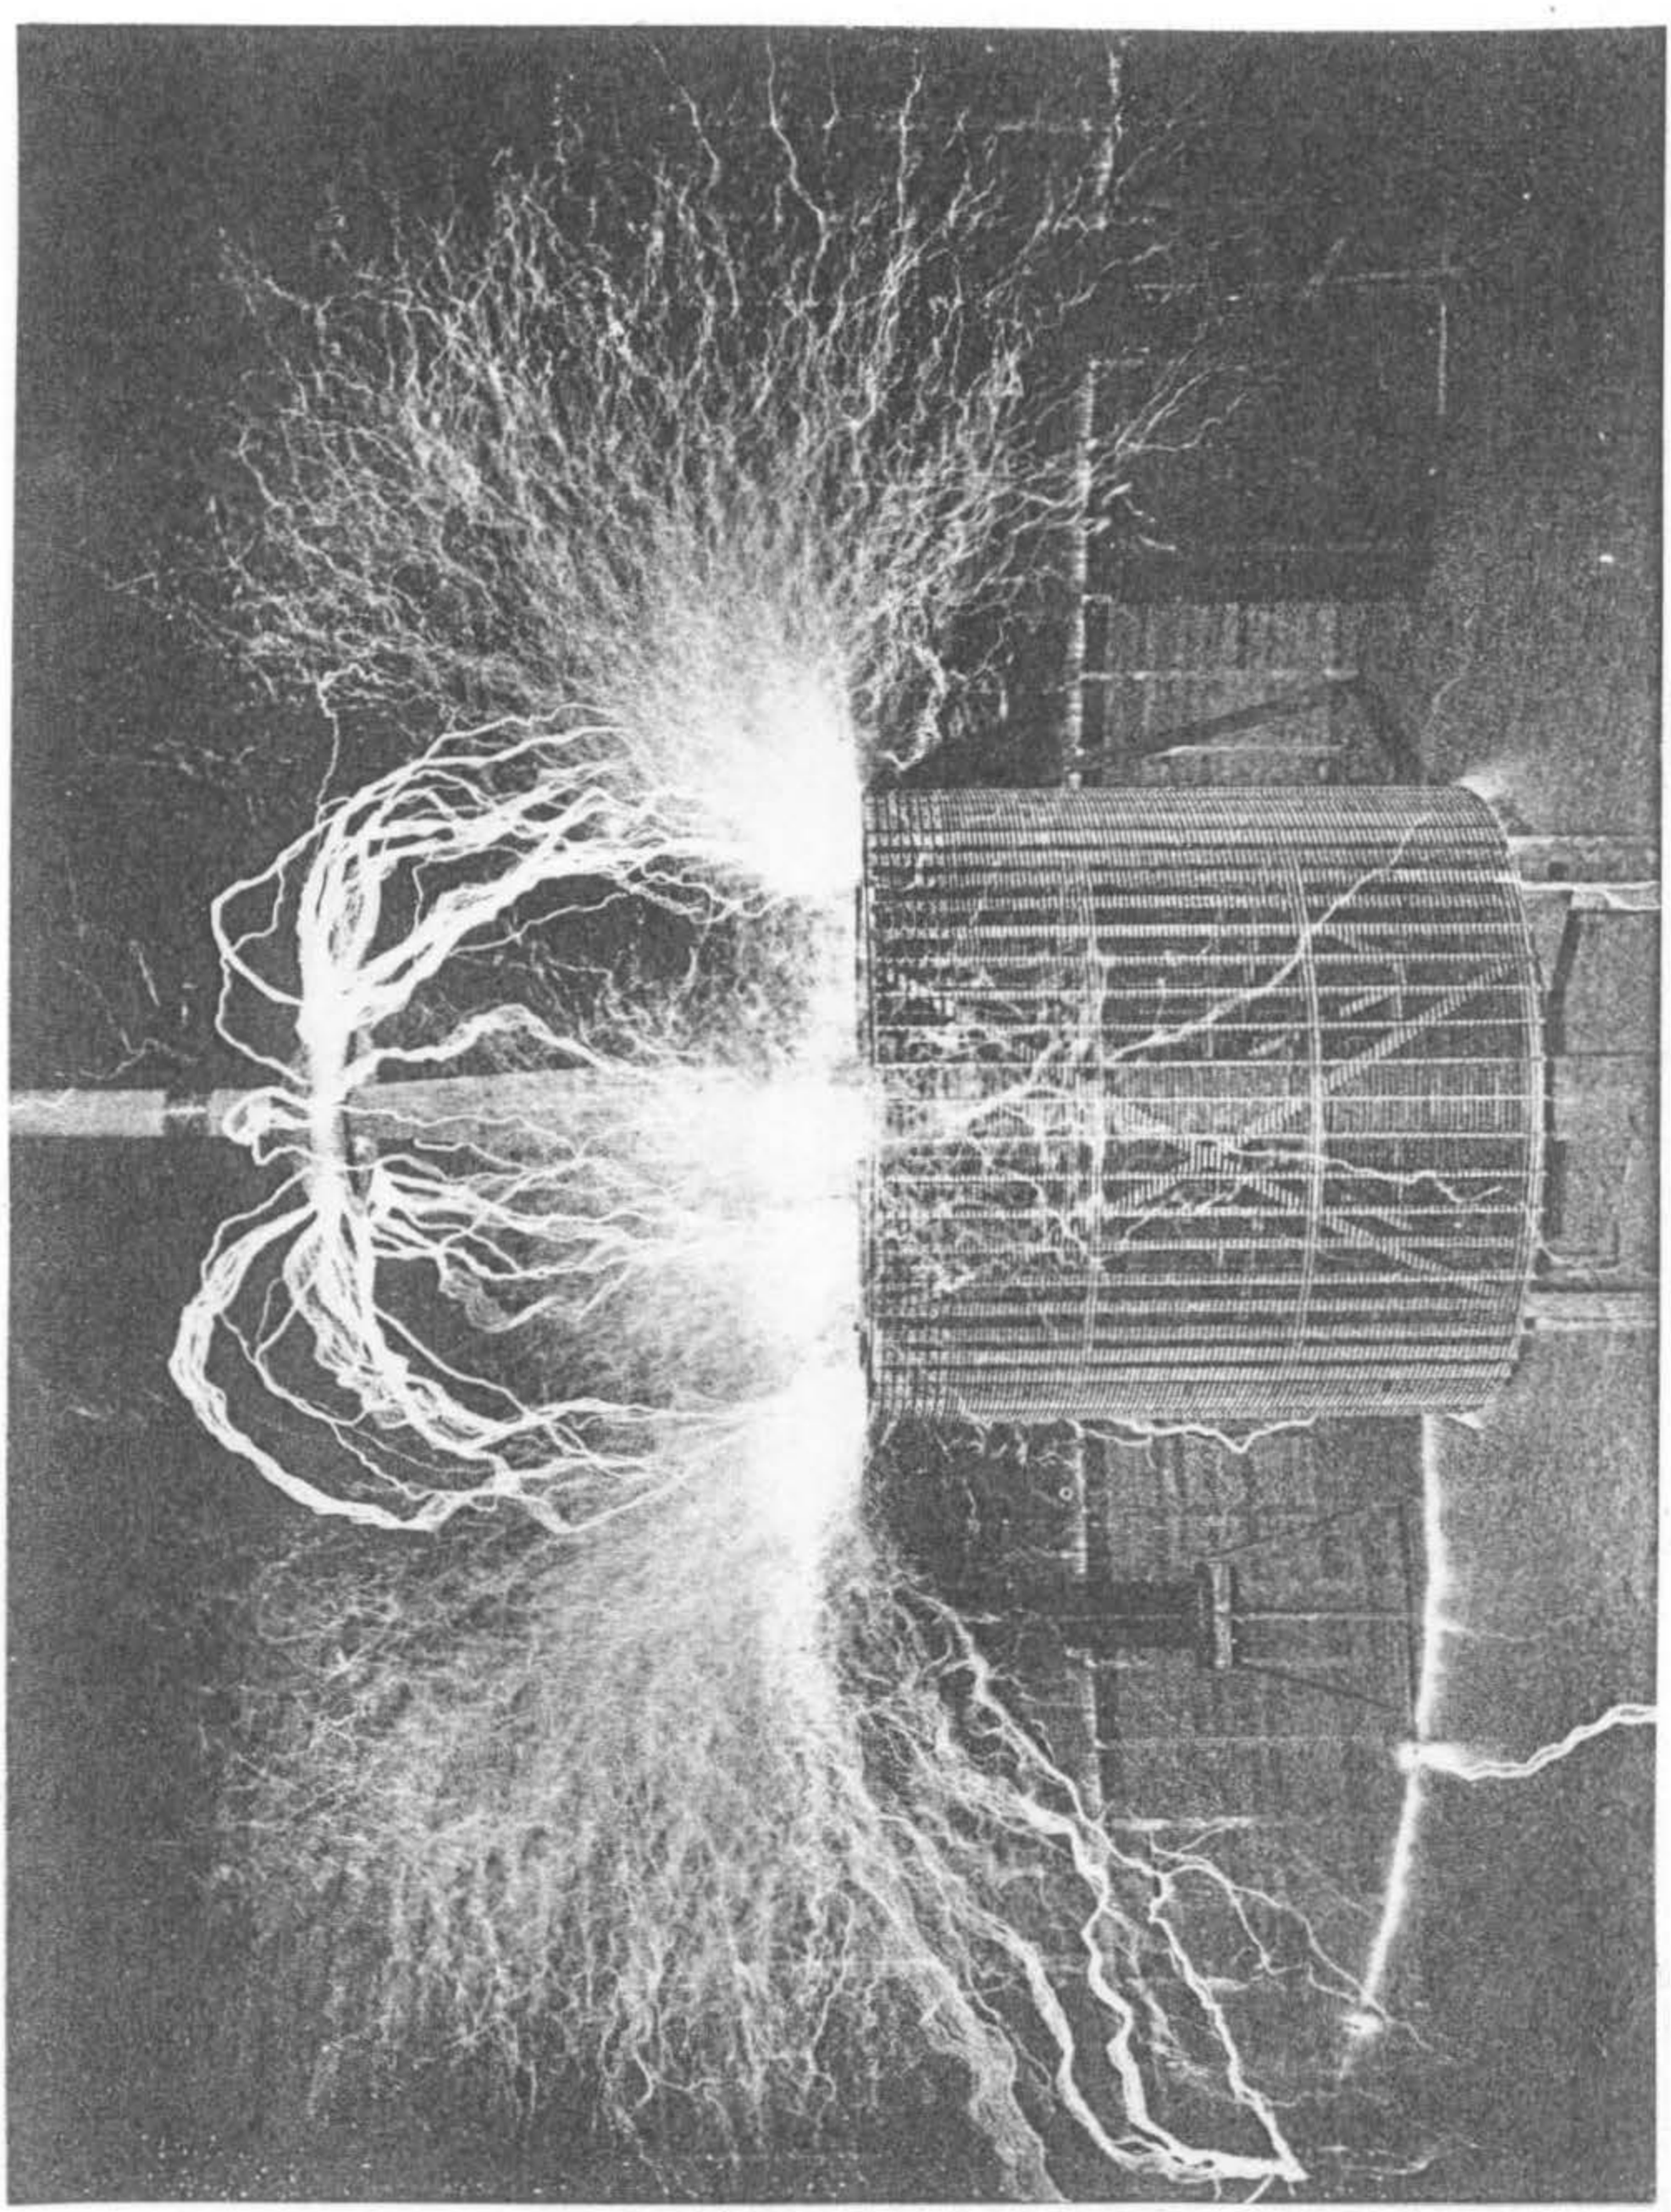

FIG. 1. BURNING THE NITROGEN OF THE ATMOSPHERE.

NOTE TO FIG. 1.—This result is produced by the discharge of an electrical oscillator giving twelve million volts. The electrical pressure, alternating one hundred thousand times per second, excites the normally inert nitrogen, causing it to combine with the oxygen. The flame-like discharge shown in the photograph measures sixty-five feet across.

think and act, we are held together, like the stars in the firmament, with ties inseparable. These ties we cannot see, but we can feel them. I cut myself in the finger, and it pains me: this finger is a part of me. I see a friend hurt, and it hurts me, too: my friend and I are one. And now I see stricken down an enemy, a lump of matter which, of all the lumps of matter in the universe, I care least for, and still it grieves me. Does this not prove that each of us is only a part of a whole?

For ages this idea has been proclaimed in the consummately wise teachings of religion, probably not alone as a means of insuring peace and harmony among men, but as a deeply founded truth. The Buddhist expresses it in one way, the Christian in another, but both say the same: We are all one. Metaphysical proofs are, however, not the only ones which we are able to bring forth in support of this idea. Science, too, recognizes this connectedness of separate individuals, though not quite in the same sense as it admits that the suns, planets, and moons of a constellation are one body, and there can be no doubt that it will be experimentally confirmed in times to come, when our means and methods for investigating psychical and other states and phenomena shall have been brought to great perfection. Still more: this one human being lives on and on. The individual is ephemeral, races and nations come and pass away, but man remains. Therein lies the profound difference between the individual and the whole. Therein, too, is to be found the partial explanation of many of those marvelous phenomena of heredity which are the result of countless centuries of feeble but persistent influence.

Conceive, then, man as a mass urged on by a force. Though this movement is not of a translatory character, implying change of place, yet the general laws of mechanical movement are applicable to it, and the energy associated with this mass can be measured, in accordance with well-known principles, by half the product of the mass with the square of a certain velocity. So, for instance, a cannon-ball which is at rest possesses a certain amount of energy in the form of heat, which we measure in a similar way. We imagine the ball to consist of innumerable minute particles, called atoms or molecules, which vibrate or whirl around one another. We determine their masses and velocities, and from them the energy of each of these minute systems, and adding them all together, we get an idea of the total heat-energy contained in the ball, which is only seemingly at rest. In this purely theoretical estimate this energy may then be calculated by multiplying half of the total mass—that is, half of the sum of all the small masses—with the square of a velocity which is determined from the velocities of the separate particles. In like manner we may conceive of human energy being measured by half the human mass multiplied with the square of a velocity which we are not yet able to compute. But our deficiency in this knowledge will not vitiate the truth of the deductions I shall draw, which rest on the firm basis that the same laws of mass and force govern throughout nature.

Man, however, is not an ordinary mass, consisting of spinning atoms and molecules, and containing merely heat-energy. He is a mass possessed of certain higher qualities by reason of the creative principle of life with which he is endowed. His mass, as the water in an ocean wave, is being continuously exchanged, new taking the place of the old. Not only this, but he grows, propagates, and dies, thus altering his mass independently, both in bulk and density. What is most wonderful of all, he is capable of increasing or diminishing his velocity of movement by the mysterious power he possesses of appropriating more or less energy from other substance, and turning it into motive energy. But in any given moment we may ignore these slow changes and assume that human energy is measured by half the product of man's mass with the square of a certain hypothetical velocity. However we may compute this velocity, and whatever we may take as the standard of its measure, we must, in harmony with this conception, come to the conclusion that the great problem of science is, and always will be, to increase the energy thus defined. Many years ago, stimulated by the perusal of that deeply interesting work, Draper's "History of the Intellectual Development of Europe," depicting so vividly human movement, I recognized that to solve this eternal problem must ever be the chief task of the man of science. Some results of my own efforts to this end I shall endeavor briefly to describe here.

Let, then, in diagram *a*, *M* represent the mass of man. This mass is impelled in one direction by a force *f*, which is resisted by another partly frictional and partly negative force *R*, acting in a direction exactly opposite, and retarding the movement of the mass. Such an antagonistic force is present

in every movement, and must be taken into consideration. The difference between these two forces is the effective force which imparts a velocity V to the mass M in the direction of the arrow on the line representing the force f. In accordance with the pre-

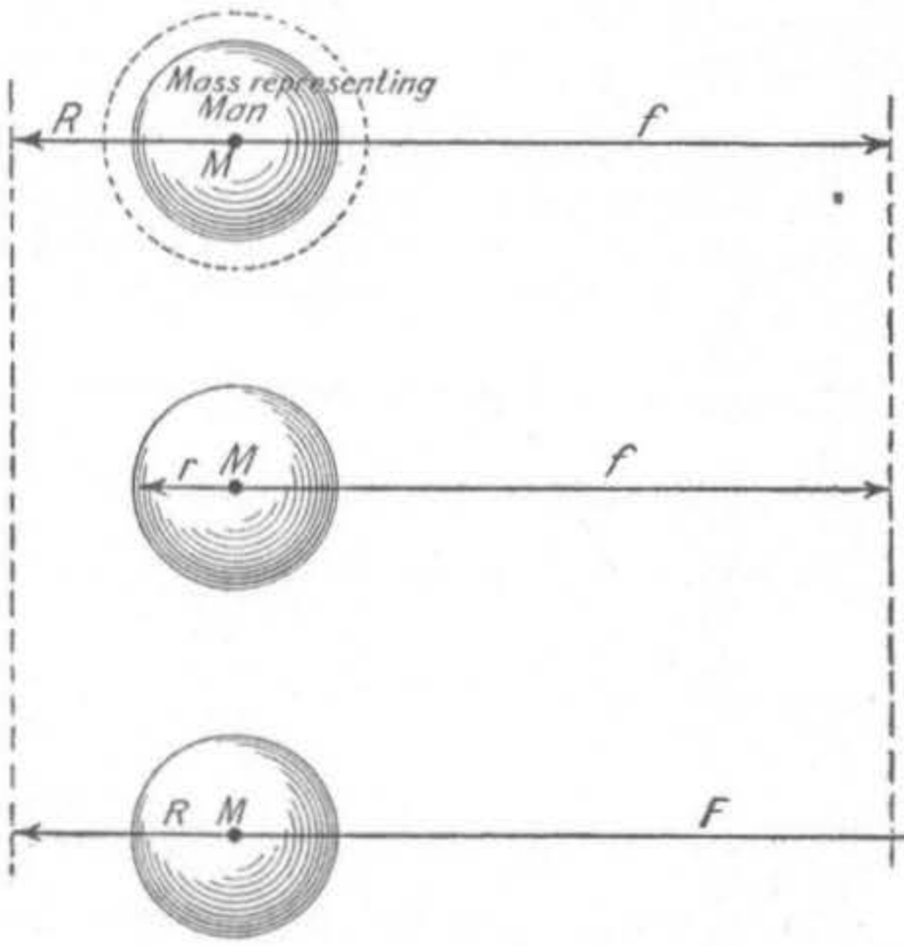

DIAGRAM *a*. THE THREE WAYS OF INCREASING HUMAN ENERGY.

ceding, the human energy will then be given by the product $\frac{1}{2} MV^2 = \frac{1}{2} MV \times V$, in which M is the total mass of man in the ordinary interpretation of the term "mass," and V is a certain hypothetical velocity, which, in the present state of science, we are unable exactly to define and determine. To increase the human energy is, therefore, equivalent to increasing this product, and there are, as will readily be seen, only three ways possible to attain this result, which are illustrated in the above diagram. The first way, shown in the top figure, is to increase the mass (as indicated by the dotted circle), leaving the two opposing forces the same. The second way is to reduce the retarding force R to a smaller value r, leaving the mass and the impelling force the same, as diagrammatically shown in the middle figure. The third way, which is illustrated in the last figure, is to increase the impelling force f to a higher value F, while the mass and the retarding force R remain unaltered. Evidently fixed limits exist as regards increase of mass and reduction of retarding force, but the impelling force can be increased indefinitely. Each of these three possible solutions presents a different aspect of the main problem of increasing human energy, which is thus divided into three distinct problems, to be successively considered.

THE FIRST PROBLEM: HOW TO INCREASE THE HUMAN MASS—THE BURNING OF ATMOSPHERIC NITROGEN.

VIEWED generally, there are obviously two ways of increasing the mass of mankind: first, by aiding and maintaining those forces and conditions which tend to increase it; and, second, by opposing and reducing those which tend to diminish it. The mass will be increased by careful attention to health, by substantial food, by moderation, by regularity of habits, by the promotion of marriage, by conscientious attention to the children, and, generally stated, by the observance of all the many precepts and laws of religion and hygiene. But in adding new mass to the old, three cases again present themselves. Either the mass added is of the same velocity as the old, or it is of a smaller or of a higher velocity. To gain an idea of the relative importance of these cases, imagine a train composed of, say, one hundred locomotives running on a track, and suppose that, to increase the energy of the moving mass, four more locomotives are added to the train. If these four move at the same velocity at which the train is going, the total energy will be increased four per cent.; if they are moving at only one half of that velocity, the increase will amount to only one per cent.; if they are moving at twice that velocity, the increase of energy will be sixteen per cent. This simple illustration shows that it is of the greatest importance to add mass of a higher velocity. Stated more to the point, if, for example, the children be of the same degree of enlightenment as the parents,—that is, mass of the "same velocity,"—the energy will simply increase proportionately to the number added. If they are less intelligent or advanced, or mass of "smaller velocity," there will be a very slight gain in the energy; but if they are further advanced, or mass of "higher velocity," then the new generation will add very considerably to the sum total of human energy. Any addition of mass of "smaller velocity," beyond that indispensable amount required by the law expressed in the proverb, "Mens sana in corpore sano," should be strenuously opposed. For instance, the mere development of muscle, as aimed at in some of our colleges, I consider equivalent to adding mass of "smaller velocity," and I would not commend it, although my views were different when I was a student myself. Moderate exercise, insuring the right balance between

mind and body, and the highest efficiency of performance, is, of course, a prime requirement. The above example shows that the most important result to be attained is the education, or the increase of the "velocity," of the mass newly added.

Conversely, it scarcely need be stated that everything that is against the teachings of religion and the laws of hygiene is tending to decrease the mass. Whisky, wine, tea, coffee, tobacco, and other such stimulants are responsible for the shortening of the lives of many, and ought to be used with moderation. But I do not think that rigorous measures of suppression of habits followed through many generations are commendable. It is wiser to preach moderation than abstinence. We have become accustomed to these stimulants, and if such reforms are to be effected, they must be slow and gradual. Those who are devoting their energies to such ends could make themselves far more useful by turning their efforts in other directions, as, for instance, toward providing pure water.

For every person who perishes from the effects of a stimulant, at least a thousand die from the consequences of drinking impure water. This precious fluid, which daily infuses new life into us, is likewise the chief vehicle through which disease and death enter our bodies. The germs of destruction it conveys are enemies all the more terrible as they perform their fatal work unperceived. They seal our doom while we live and enjoy. The majority of people are so ignorant or careless in drinking water, and the consequences of this are so disastrous, that a philanthropist can scarcely use his efforts better than by endeavoring to enlighten those who are thus injuring themselves. By systematic purification and sterilization of the drinking-water the human mass would be very considerably increased. It should be made a rigid rule—which might be enforced by law—to boil or to sterilize otherwise the drinking-water in every household and public place. The mere filtering does not afford sufficient security against infection. All ice for internal uses should be artificially prepared from water thoroughly sterilized. The importance of eliminating germs of disease from the city water is generally recognized, but little is being done to improve the existing conditions, as no satisfactory method of sterilizing great quantities of water has as yet been brought forward. By improved electrical appliances we are now enabled to produce ozone cheaply and in large amounts, and this ideal disinfectant seems to offer a happy solution of the important question.

Gambling, business rush, and excitement, particularly on the exchanges, are causes of much mass-reduction, all the more so because the individuals concerned represent units of higher value. Incapacity of observing the first symptoms of an illness, and careless neglect of the same, are important factors of mortality. In noting carefully every new sign of approaching danger, and making conscientiously every possible effort to avert it, we are not only following wise laws of hygiene in the interest of our well-being and the success of our labors, but we are also complying with a higher moral duty. Every one should consider his body as a priceless gift from one whom he loves above all, as a marvelous work of art, of undescribable beauty and mastery beyond human conception, and so delicate and frail that a word, a breath, a look, nay, a thought, may injure it. Uncleanliness, which breeds disease and death, is not only a self-destructive but a highly immoral habit. In keeping our bodies free from infection, healthful, and pure, we are expressing our reverence for the high principle with which they are endowed. He who follows the precepts of hygiene in this spirit is proving himself, so far, truly religious. Laxity of morals is a terrible evil, which poisons both mind and body, and which is responsible for a great reduction of the human mass in some countries. Many of the present customs and tendencies are productive of similar hurtful results. For example, the society life, modern education and pursuits of women, tending to draw them away from their household duties and make men out of them, must needs detract from the elevating ideal they represent, diminish the artistic creative power, and cause sterility and a general weakening of the race. A thousand other evils might be mentioned, but all put together, in their bearing upon the problem under discussion, they would not equal a single one, the want of food, brought on by poverty, destitution, and famine. Millions of individuals die yearly for want of food, thus keeping down the mass. Even in our enlightened communities, and notwithstanding the many charitable efforts, this is still, in all probability, the chief evil. I do not mean here absolute want of food, but want of healthful nutriment.

How to provide good and plentiful food is, therefore, a most important question of the day. On general principles the raising of cattle as a means of providing food is

objectionable, because, in the sense interpreted above, it must undoubtedly tend to the addition of mass of a "smaller velocity." It is certainly preferable to raise vegetables, and I think, therefore, that vegetarianism is a commendable departure from the established barbarous habit. That we can subsist on plant food and perform our work even to advantage is not a theory, but a well-demonstrated fact. Many races living almost exclusively on vegetables are of superior physique and strength. There is no doubt that some plant food, such as oatmeal, is more economical than meat, and superior to it in regard to both mechanical and mental performance. Such food, moreover, taxes our digestive organs decidedly less, and, in making us more contented and sociable, produces an amount of good difficult to estimate. In view of these facts every effort should be made to stop the wanton and cruel slaughter of animals, which must be destructive to our morals. To free ourselves from animal instincts and appetites, which keep us down, we should begin at the very root from which they spring: we should effect a radical reform in the character of the food.

There seems to be no *philosophical* necessity for food. We can conceive of organized beings living without nourishment, and deriving all the energy they need for the performance of their life-functions from the ambient medium. In a crystal we have the clear evidence of the existence of a formative life-principle, and though we cannot understand the life of a crystal, it is none the less a living being. There may be, besides crystals, other such individualized, material systems of beings, perhaps of gaseous constitution, or composed of substance still more tenuous. In view of this possibility,—nay, probability,—we cannot apodictically deny the existence of organized beings on a planet merely because the conditions on the same are unsuitable for the existence of life as we conceive it. We cannot even, with positive assurance, assert that some of them might not be present here, in this our world, in the very midst of us, for their constitution and life-manifestation may be such that we are unable to perceive them.

The production of artificial food as a means for causing an increase of the human mass naturally suggests itself, but a direct attempt of this kind to provide nourishment does not appear to me rational, at least not for the present. Whether we could thrive on such food is very doubtful. We are the result of ages of continuous adaptation, and we cannot radically change without unforeseen and, in all probability, disastrous consequences. So uncertain an experiment should not be tried. By far the best way, it seems to me, to meet the ravages of the evil, would be to find ways of increasing the productivity of the soil. With this object the preservation of forests is of an importance which cannot be overestimated, and in this connection, also, the utilization of water-power for purposes of electrical transmission, dispensing in many ways with the necessity of burning wood, and tending thereby to forest preservation, is to be strongly advocated. But there are limits in the improvement to be effected in this and similar ways.

To increase materially the productivity of the soil, it must be more effectively fertilized by artificial means. The question of food-production resolves itself, then, into the question how best to fertilize the soil. What it is that made the soil is still a mystery. To explain its origin is probably equivalent to explaining the origin of life itself. The rocks, disintegrated by moisture and heat and wind and weather, were in themselves not capable of maintaining life. Some unexplained condition arose, and some new principle came into effect, and the first layer capable of sustaining low organisms, like mosses, was formed. These, by their life and death, added more of the life-sustaining quality to the soil, and higher organisms could then subsist, and so on and on, until at last highly developed plant and animal life could flourish. But though the theories are, even now, not in agreement as to how fertilization is effected, it is a fact, only too well ascertained, that the soil cannot indefinitely sustain life, and some way must be found to supply it with the substances which have been abstracted from it by the plants. The chief and most valuable among these substances are compounds of nitrogen, and the cheap production of these is, therefore, the key for the solution of the all-important food problem. Our atmosphere contains an inexhaustible amount of nitrogen, and could we but oxidize it and produce these compounds, an incalculable benefit for mankind would follow.

Long ago this idea took a powerful hold on the imagination of scientific men, but an efficient means for accomplishing this result could not be devised. The problem was rendered extremely difficult by the extraordinary inertness of the nitrogen, which refuses to

combine even with oxygen. But here electricity comes to our aid: the dormant affinities of the element are awakened by an electric current of the proper quality. As a lump of coal which has been in contact with oxygen for centuries without burning will combine with it when once ignited, so nitrogen, excited by electricity, will burn. I did not succeed, however, in producing electrical discharges exciting very effectively the atmospheric nitrogen until a comparatively recent date, although I showed, in May, 1891, in a scientific lecture, a novel form of discharge or electrical flame named "St. Elmo's hotfire," which, besides being capable of generating ozone in abundance, also possessed, as I pointed out on that occasion, distinctly the quality of exciting chemical affinities. This discharge or flame was then only three or four inches long, its chemical action was likewise very feeble, and consequently the process of oxidation of the nitrogen was wasteful. How to intensify this action was the question. Evidently electric currents of a peculiar kind had to be produced in order to render the process of nitrogen combustion more efficient.

The first advance was made in ascertaining that the chemical activity of the discharge was very considerably increased by using currents of extremely high frequency or rate of vibration. This was an important improvement, but practical considerations soon set a definite limit to the progress in this direction. Next, the effects of the electrical pressure of the current impulses, of their wave-form and other characteristic features, were investigated. Then the influence of the atmospheric pressure and temperature and of the presence of water and other bodies was studied, and thus the best conditions for causing the most intense chemical action of the discharge and securing the highest efficiency of the process were gradually ascertained. Naturally, the improvements were not quick in coming; still, little by little, I advanced. The flame grew larger and larger, and its oxidizing action more and more intense. From an insignificant brush-discharge a few inches long it developed into a marvelous electrical phenomenon, a roaring blaze, devouring the nitrogen of the atmosphere and measuring sixty or seventy feet across. Thus slowly, almost imperceptibly, possibility became accomplishment. All is not yet done, by any means, but to what a degree my efforts have been rewarded an idea may be gained from an inspection of Fig. 1 (p. 176), which, with its title, is self-explanatory. The flame-like discharge visible is produced by the intense electrical oscillations which pass through the coil shown, and violently agitate the electrified molecules of the air. By this means a strong affinity is created between the two normally indifferent constituents of the atmosphere, and they combine readily, even if no further provision is made for intensifying the chemical action of the discharge. In the manufacture of nitrogen compounds by this method, of course, every possible means bearing upon the intensity of this action and the efficiency of the process will be taken advantage of, and, besides, special arrangements will be provided for the fixation of the compounds formed, as they are generally unstable, the nitrogen becoming again inert after a little lapse of time. Steam is a simple and effective means for fixing permanently the compounds. The result illustrated makes it practicable to oxidize the atmospheric nitrogen in unlimited quantities, merely by the use of cheap mechanical power and simple electrical apparatus. In this manner many compounds of nitrogen may be manufactured all over the world, at a small cost, and in any desired amount, and by means of these compounds the soil can be fertilized and its productiveness indefinitely increased. An abundance of cheap and healthful food, not artificial, but such as we are accustomed to, may thus be obtained. This new and inexhaustible source of food-supply will be of incalculable benefit to mankind, for it will enormously contribute to the increase of the human mass, and thus add immensely to human energy. Soon, I hope, the world will see the beginning of an industry which, in time to come, will, I believe, be in importance next to that of iron.

THE SECOND PROBLEM: HOW TO REDUCE THE FORCE RETARDING THE HUMAN MASS—THE ART OF TELAUTOMATICS.

As before stated, the force which retards the onward movement of man is partly frictional and partly negative. To illustrate this distinction I may name, for example, ignorance, stupidity, and imbecility as some of the purely frictional forces, or resistances devoid of any directive tendency. On the other hand, visionariness, insanity, self-destructive tendency, religious fanaticism, and the like, are all forces of a negative character, acting in definite directions. To reduce or entirely to overcome these dissimilar retarding forces, radically different methods must be employed. One knows, for instance, what

a fanatic may do, and one can take preventive measures, can enlighten, convince, and possibly direct him, turn his vice into virtue; but one does not know, and never can know, what a brute or an imbecile may do, and one must deal with him as with a mass, inert, without mind, let loose by the mad elements. A negative force always implies some quality, not infrequently a high one, though badly directed, which it is possible to turn to good advantage; but a directionless, frictional force involves unavoidable loss. Evidently, then, the first and general answer to the above question is: turn all negative force in the right direction and reduce all frictional force.

There can be no doubt that, of all the frictional resistances, the one that most retards human movement is ignorance. Not without reason said that man of wisdom, Buddha: "Ignorance is the greatest evil in the world." The friction which results from ignorance, and which is greatly increased owing to the numerous languages and nationalities, can be reduced only by the spread of knowledge and the unification of the heterogeneous elements of humanity. No effort could be better spent. But however ignorance may have retarded the onward movement of man in times past, it is certain that, nowadays, negative forces have become of greater importance. Among these there is one of far greater moment than any other. It is called organized warfare. When we consider the millions of individuals, often the ablest in mind and body, the flower of humanity, who are compelled to a life of inactivity and unproductiveness, the immense sums of money daily required for the maintenance of armies and war apparatus, representing ever so much of human energy, all the effort uselessly spent in the production of arms and implements of destruction, the loss of life and the fostering of a barbarous spirit, we are appalled at the inestimable loss to mankind which the existence of these deplorable conditions must involve. What can we do to combat best this great evil?

Law and order absolutely require the maintenance of organized force. No community can exist and prosper without rigid discipline. Every country must be able to defend itself, should the necessity arise. The conditions of to-day are not the result of yesterday, and a radical change cannot be effected to-morrow. If the nations would at once disarm, it is more than likely that a state of things worse than war itself would follow. Universal peace is a beautiful dream, but not at once realizable. We have seen recently that even the noble effort of the man invested with the greatest worldly power has been virtually without effect. And no wonder, for the establishment of universal peace is, for the time being, a physical impossibility. War is a negative force, and cannot be turned in a positive direction without passing through the intermediate phases. It is the problem of making a wheel, rotating one way, turn in the opposite direction without slowing it down, stopping it, and speeding it up again the other way.

It has been argued that the perfection of guns of great destructive power will stop warfare. So I myself thought for a long time, but now I believe this to be a profound mistake. Such developments will greatly modify, but not arrest it. On the contrary, I think that every new arm that is invented, every new departure that is made in this direction, merely invites new talent and skill, engages new effort, offers a new incentive, and so only gives a fresh impetus to further development. Think of the discovery of gunpowder. Can we conceive of any more radical departure than was effected by this innovation? Let us imagine ourselves living in that period: would we not have thought then that warfare was at an end, when the armor of the knight became an object of ridicule, when bodily strength and skill, meaning so much before, became of comparatively little value? Yet gunpowder did not stop warfare; quite the opposite—it acted as a most powerful incentive. Nor do I believe that warfare can ever be arrested by any scientific or ideal development, so long as similar conditions to those now prevailing exist, because war has itself become a science, and because war involves some of the most sacred sentiments of which man is capable. In fact, it is doubtful whether men who would not be ready to fight for a high principle would be good for anything at all. It is not the mind which makes man, nor is it the body; it is mind and body. Our virtues and our failings are inseparable, like force and matter. When they separate, man is no more.

Another argument, which carries considerable force, is frequently made, namely, that war must soon become impossible because the means of defense are outstripping the means of attack. This is only in accordance with a fundamental law which may be expressed by the statement that it is easier to destroy than to build. This law defines human capacities and human conditions.

Were these such that it would be easier to build than to destroy, man would go on unresisted, creating and accumulating without limit. Such conditions are not of this earth. A being which could do this would not be a man; it might be a god. Defense will always have the advantage over attack, but this alone, it seems to me, can never stop war. By the use of new principles of defense we can render harbors impregnable against attack, but we cannot by such means prevent two war-ships meeting in battle on the high sea. And then, if we follow this idea to its ultimate development, we are led to the conclusion that it would be better for mankind if attack and defense were just oppositely related; for if every country, even the smallest, could surround itself with a wall absolutely impenetrable, and could defy the rest of the world, a state of things would surely be brought on which would be extremely unfavorable to human progress. It is by abolishing all the barriers which separate nations and countries that civilization is best furthered.

Again, it is contended by some that the advent of the flying-machine must bring on universal peace. This, too, I believe to be an entirely erroneous view. The flying-machine is certainly coming, and very soon, but the conditions will remain the same as before. In fact, I see no reason why a ruling power, like Great Britain, might not govern the air as well as the sea. Without wishing to put myself on record as a prophet, I do not hesitate to say that the next years will see the establishment of an "air-power," and its center may not be far from New York. But, for all that, men will fight on merrily.

The ideal development of the war principle would ultimately lead to the transformation of the whole energy of war into purely potential, explosive energy, like that of an electrical condenser. In this form the war-energy could be maintained without effort; it would need to be much smaller in amount, while incomparably more effective.

As regards the security of a country against foreign invasion, it is interesting to note that it depends only on the relative, and not on the absolute, number of the individuals or magnitude of the forces, and that, if every country should reduce the war-force in the same ratio, the security would remain unaltered. An international agreement with the object of reducing to a minimum the war-force which, in view of the present still imperfect education of the masses, is absolutely indispensable, would, therefore, seem to be the first rational step to take toward diminishing the force retarding human movement.

Fortunately, the existing conditions cannot continue indefinitely, for a new element is beginning to assert itself. A change for the better is imminent, and I shall now endeavor to show what, according to my ideas, will be the first advance toward the establishment of peaceful relations between nations, and by what means it will eventually be accomplished.

Let us go back to the early beginning, when the law of the stronger was the only law. The light of reason was not yet kindled, and the weak was entirely at the mercy of the strong. The weak individual then began to learn how to defend himself. He made use of a club, stone, spear, sling, or bow and arrow, and in the course of time, instead of physical strength, intelligence became the chief deciding factor in the battle. The wild character was gradually softened by the awakening of noble sentiments, and so, imperceptibly, after ages of continued progress, we have come from the brutal fight of the unreasoning animal to what we call the "civilized warfare" of to-day, in which the combatants shake hands, talk in a friendly way, and smoke cigars in the entr'actes, ready to engage again in deadly conflict at a signal. Let pessimists say what they like, here is an absolute evidence of great and gratifying advance.

But now, what is the next phase in this evolution? Not peace as yet, by any means. The next change which should naturally follow from modern developments should be the continuous diminution of the number of individuals engaged in battle. The apparatus will be one of specifically great power, but only a few individuals will be required to operate it. This evolution will bring more and more into prominence a machine or mechanism with the fewest individuals as an element of warfare, and the absolutely unavoidable consequence of this will be the abandonment of large, clumsy, slowly moving, and unmanageable units. Greatest possible speed and maximum rate of energy-delivery by the war apparatus will be the main object. The loss of life will become smaller and smaller, and finally, the number of the individuals continuously diminishing, merely machines will meet in a contest without bloodshed, the nations being simply interested, ambitious spectators. When this happy condition is realized, peace will be assured. But, no matter to what degree of perfection rapid-

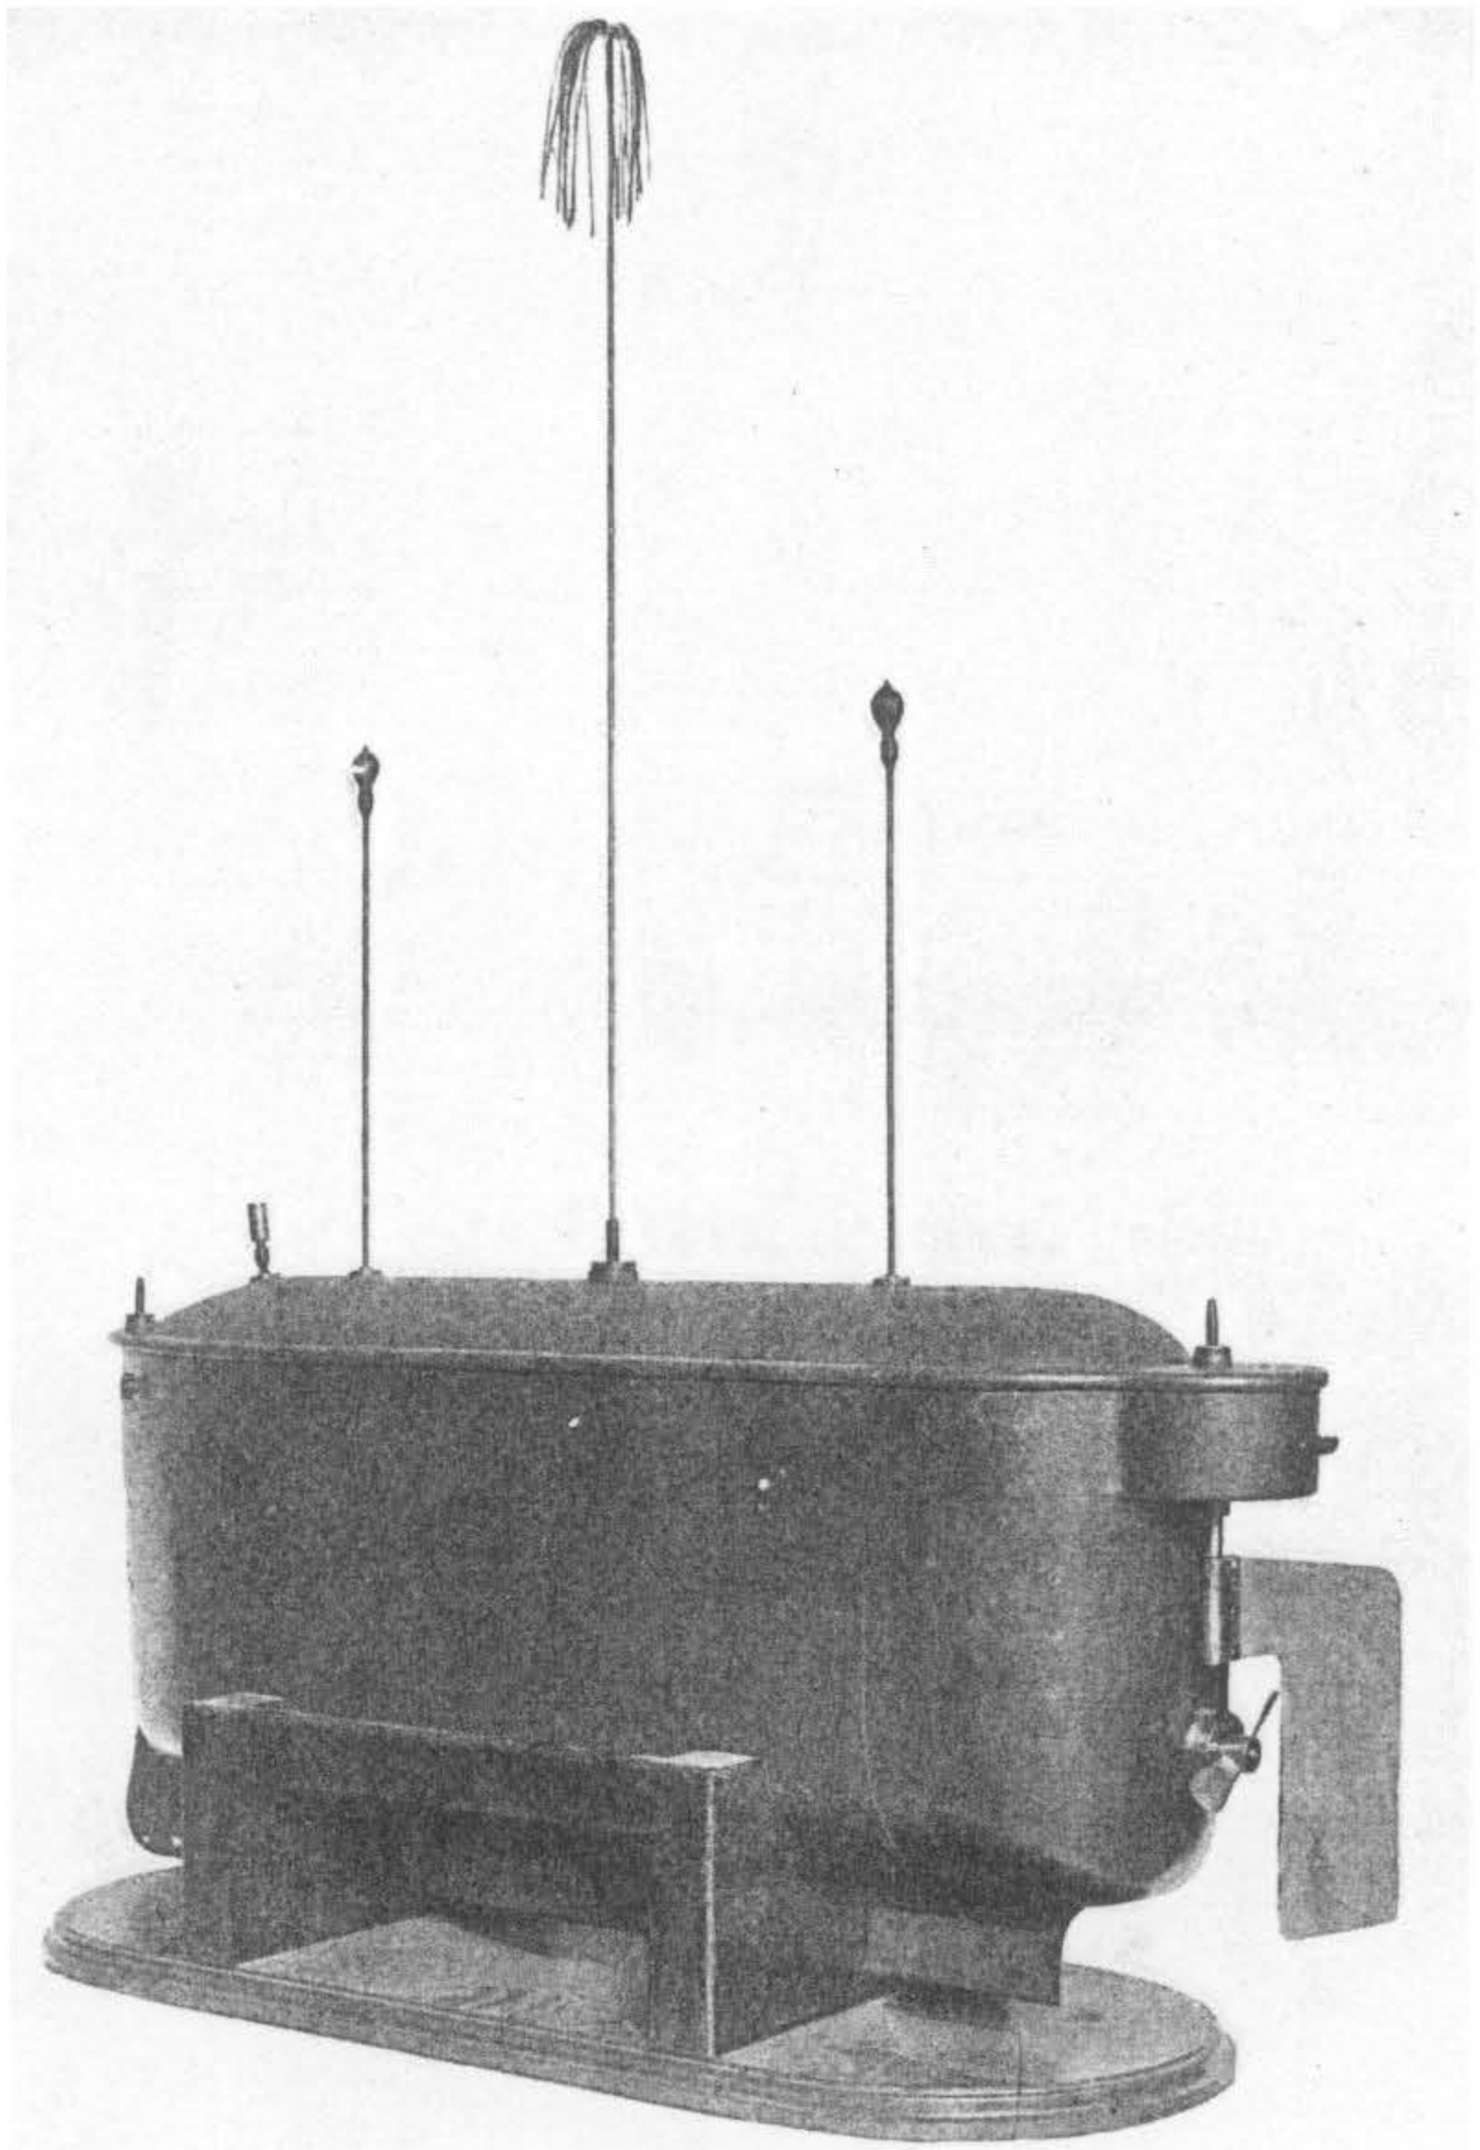

FIG. 2. THE FIRST PRACTICAL TELAUTOMATON.

A machine having all its bodily or translatory movements and the operations of the interior mechanism controlled from a distance without wires. The crewless boat shown in the photograph contains its own motive power, propelling- and steering-machinery, and numerous other accessories, all of which are controlled by transmitting from a distance, without wires, electrical oscillations to a circuit carried by the boat and adjusted to respond only to these oscillations.

speak. As to the capacity for propagation, it could likewise be left out of consideration, for in the mechanical model it merely signified a process of manufacture. Whether the automaton be of flesh and bone, or of wood and steel, it mattered little, provided it could perform all the duties required of it like an intelligent being. To do so, it had to have an element corresponding to the mind, which would effect the control of all its movements and operations, and cause it to act, in any unforeseen case that might present itself, with knowledge, reason, judgment, and experience. But this element I could easily embody in it by conveying to it my own intelligence, my own understanding. So this invention was evolved, and so a new art came into existence, for which the name

fire guns, high-power cannon, explosive projectiles, torpedo-boats, or other implements of war may be brought, no matter how destructive they may be made, that condition can never be reached through any such development. All such implements require men for their operation; men are indispensable parts of the machinery. Their object is to kill and to destroy. Their power resides in their capacity for doing evil. So long as men meet in battle, there will be bloodshed. Bloodshed will ever keep up barbarous passion. To break this fierce spirit, a radical departure must be made, an entirely new principle must be introduced, something that never existed before in warfare—a principle which will forcibly, unavoidably, turn the battle into a mere spectacle, a play, a contest without loss of blood. To bring on this result men must be dispensed with: machine must fight machine. But how accomplish that which seems impossible? The answer is simple enough: produce a machine capable of acting as though it were part of a human being—no mere mechanical contrivance, comprising levers, screws, wheels, clutches, and nothing more, but a machine embodying a higher principle, which will enable it to perform its duties as though it had intelligence, experience, reason, judgment, a mind! This conclusion is the result of my thoughts and observations which have extended through virtually my whole life, and I shall now briefly describe how I came to accomplish that which at first seemed an unrealizable dream.

A long time ago, when I was a boy, I was afflicted with a singular trouble, which seems to have been due to an extraordinary excitability of the retina. It was the appearance of images which, by their persistence, marred the vision of real objects and interfered with thought. When a word was said to me, the image of the object which it designated would appear vividly before my eyes, and many times it was impossible for me to tell whether the object I saw was real or not. This caused me great discomfort and anxiety, and I tried hard to free myself of the spell. But for a long time I tried in vain, and it was not, as I still clearly recollect, until I was about twelve years old that I succeeded for the first time, by an effort of the will, in banishing an image which presented itself. My happiness will never be as complete as it was then, but, unfortunately (as I thought at that time), the old trouble returned, and with it my anxiety. Here it was that the observations to which I refer began. I noted, namely, that whenever the image of an object appeared before my eyes I had seen something which reminded me of it. In the first instances I thought this to be purely accidental, but soon I convinced myself that it was not so. A visual impression, consciously or unconsciously received, invariably preceded the appearance of the image. Gradually the desire arose in me to find out, every time, what caused the images to appear, and the satisfaction of this desire soon became a necessity. The next observation I made was that, just as these images followed as a result of something I had seen, so also the thoughts which I conceived were suggested in like manner. Again, I experienced the same desire to locate the image which caused the thought, and this search for the original visual impression soon grew to be a second nature. My mind became automatic, as it were, and in the course of years of continued, almost unconscious performance, I acquired the ability of locating every time and, as a rule, instantly the visual impression which started the thought. Nor is this all. It was not long before I was aware that also all my movements were prompted in the same way, and so, searching, observing, and verifying continuously, year after year, I have, by every thought and every act of mine, demonstrated, and do so daily, to my absolute satisfaction, that I am an automaton endowed with power of movement, which merely responds to external stimuli beating upon my sense organs, and thinks and acts and moves accordingly. I remember only one or two cases in all my life in which I was unable to locate the first impression which prompted a movement or a thought, or even a dream.

With these experiences it was only natural that, long ago, I conceived the idea of constructing an automaton which would mechanically represent me, and which would respond, as I do myself, but, of course, in a much more primitive manner, to external influences. Such an automaton evidently had to have motive power, organs for locomotion, directive organs, and one or more sensitive organs so adapted as to be excited by external stimuli. This machine would, I reasoned, perform its movements in the manner of a living being, for it would have all the chief mechanical characteristics or elements of the same. There was still the capacity for growth, propagation, and, above all, the mind which would be wanting to make the model complete. But growth was not necessary in this case, since a machine could be manufactured full-grown, so to

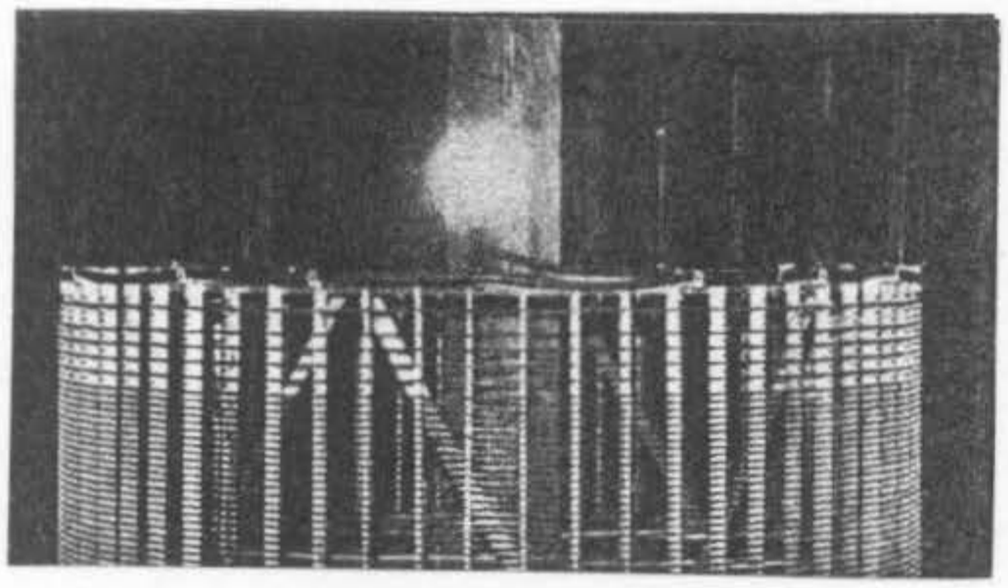

FIG. 3. EXPERIMENT TO ILLUSTRATE THE SUPPLYING OF ELECTRICAL ENERGY THROUGH A SINGLE WIRE WITHOUT RETURN.

An ordinary incandescent lamp, connected with one or both of its terminals to the wire forming the upper free end of the coil shown in the photograph, is lighted by electrical vibrations conveyed to it through the coil from an electrical oscillator, which is worked only to one fifth of one per cent. of its full capacity.

"telautomatics" has been suggested, which means the art of controlling the movements and operations of distant automatons.

This principle evidently was applicable to any kind of machine that moves on land or in the water or in the air. In applying it practically for the first time, I selected a boat (see Fig. 2). A storage battery placed within it furnished the motive power. The propeller, driven by a motor, represented the locomotive organs. The rudder, controlled by another motor likewise driven by the battery, took the place of the directive organs. As to the sensitive organ, obviously the first thought was to utilize a device responsive to rays of light, like a selenium cell, to represent the human eye. But upon closer inquiry I found that, owing to experimental and other difficulties, no thoroughly satisfactory control of the automaton could be effected by light, radiant heat, Hertzian radiations, or by rays in general, that is, disturbances which pass in straight lines through space. One of the reasons was that any obstacle coming between the operator and the distant automaton would place it beyond his control. Another reason was that the sensitive device representing the eye would have to be in a definite position with respect to the distant controlling apparatus, and this necessity would impose great limitations in the control. Still another and very important reason was that, in using rays, it would be difficult, if not impossible, to give to the automaton individual features or characteristics distinguishing it from other machines of this kind. Evidently the automaton should respond only to an individual call, as a person responds to a name. Such considerations led me to conclude that the sensitive device of the machine should correspond to the ear rather than to the eye of a human being, for in this case its actions could be controlled irrespective of intervening obstacles, regardless of its position relative to the distant controlling apparatus, and, last, but not least, it would remain deaf and unresponsive, like a faithful servant, to all calls but that of its master. These requirements made it imperative to use, in the control of the automaton, instead of light- or other rays, waves or disturbances which propagate in all directions through space, like sound, or which follow a path of least resistance, however curved. I attained the result aimed at by means of an electric circuit placed within the boat, and adjusted, or "tuned," exactly to electrical vibrations of the proper kind transmitted to it from a

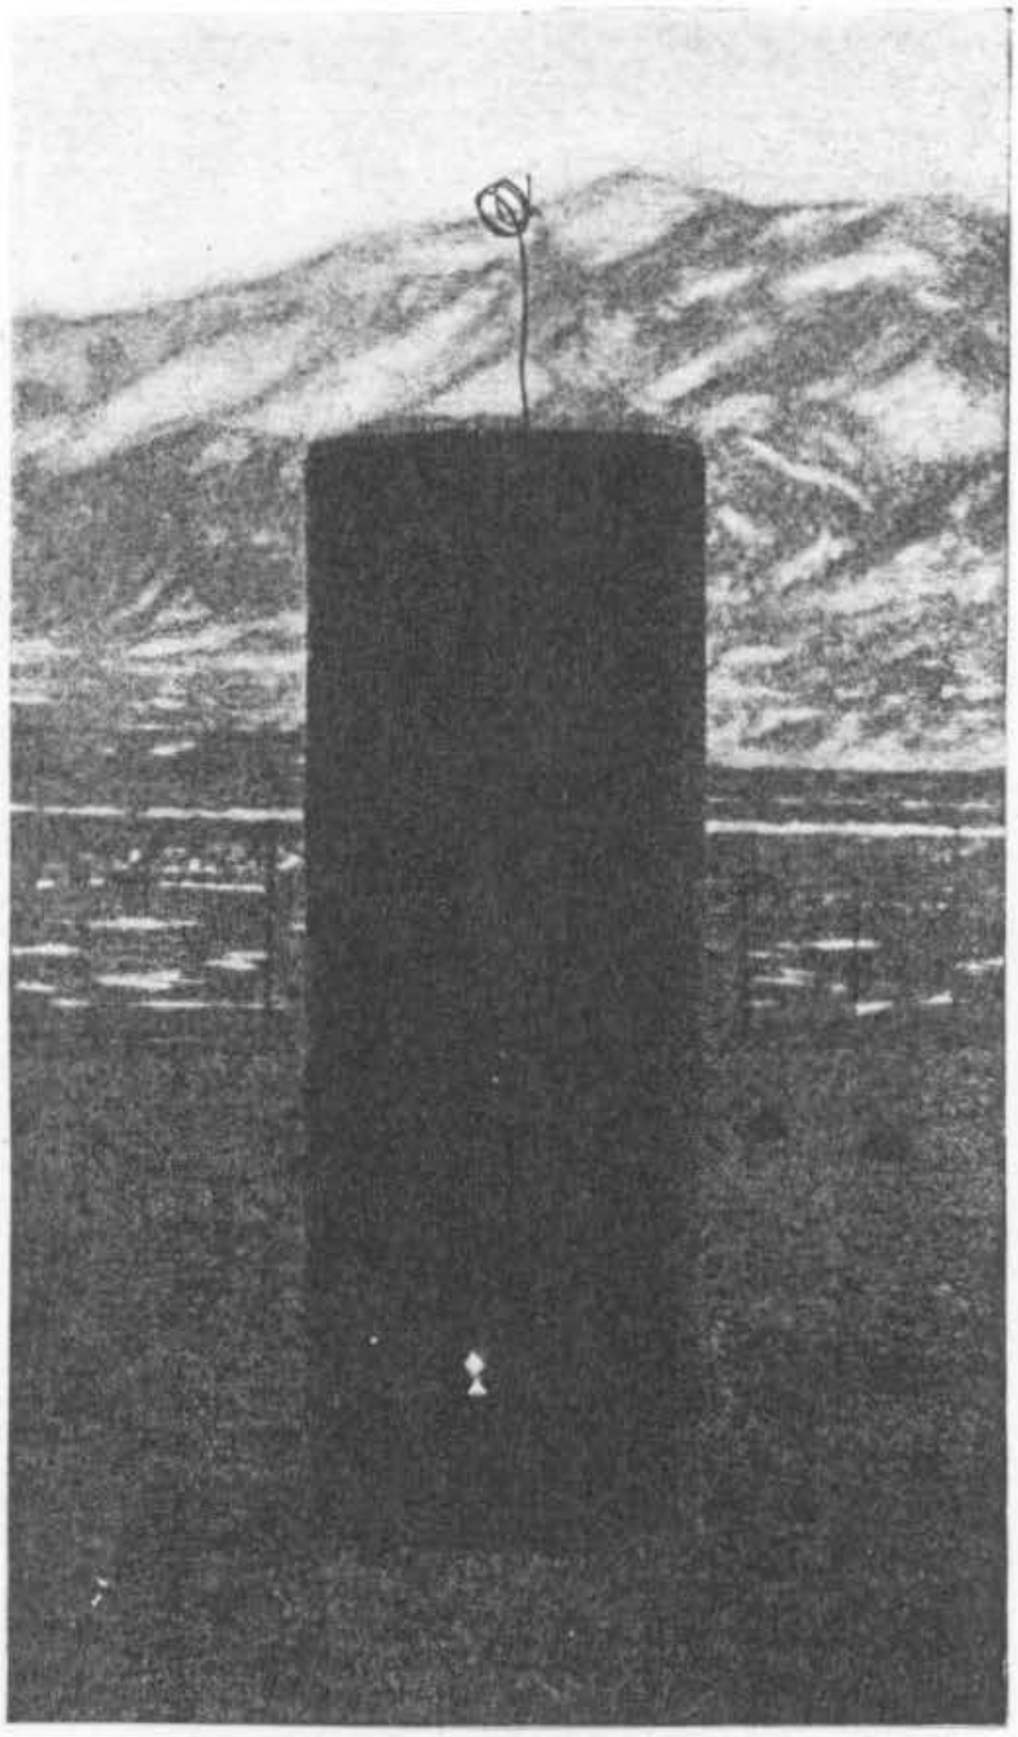

FIG. 4. EXPERIMENT TO ILLUSTRATE THE TRANSMISSION OF ELECTRICAL ENERGY THROUGH THE EARTH WITHOUT WIRE.

The coil shown in the photograph has its lower end or terminal connected to the ground, and is exactly attuned to the vibrations of a distant electrical oscillator. The lamp lighted is in an independent wire loop, energized by induction from the coil excited by the electrical vibrations transmitted to it through the ground from the oscillator, which is worked only to five per cent. of its full capacity.

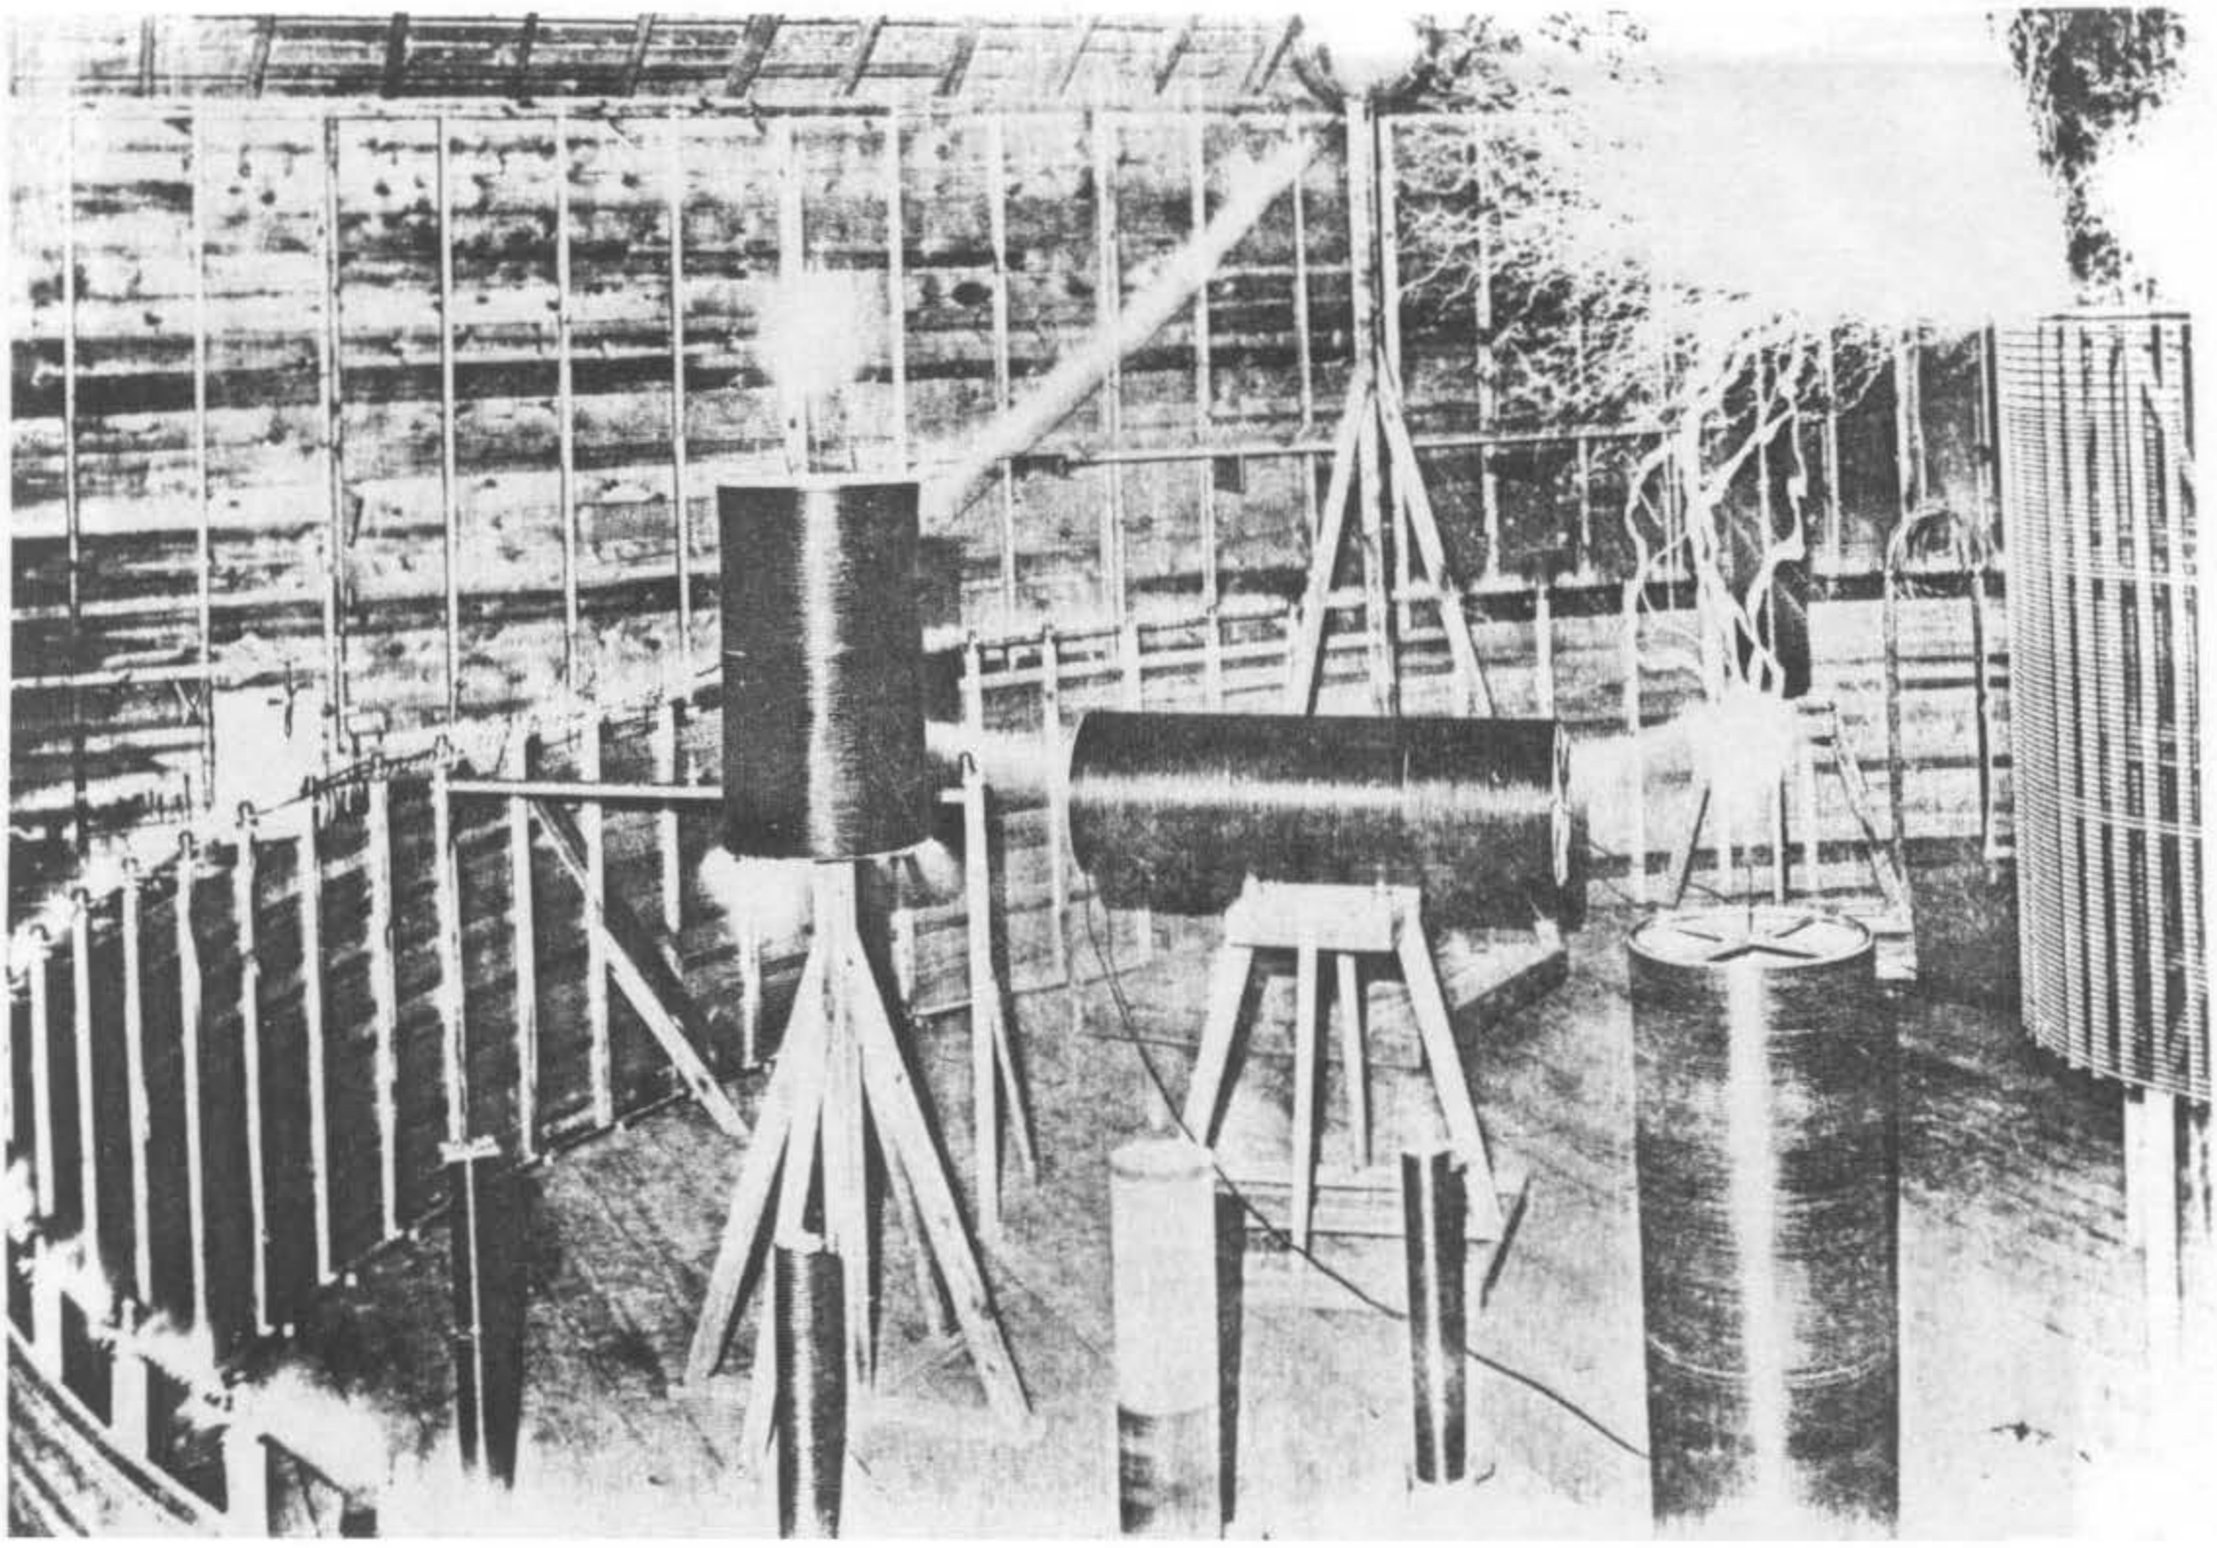

FIG. 5. PHOTOGRAPHIC VIEW OF COILS RESPONDING TO ELECTRICAL OSCILLATIONS.

The picture shows a number of coils, differently attuned and responding to the vibrations transmitted to them through the earth from an electrical oscillator. The large coil on the right, discharging strongly, is tuned to the fundamental vibration, which is fifty thousand per second; the two larger vertical coils to twice that number; the smaller white wire coil to four times that number, and the remaining small coils to higher tones. The vibrations produced by the oscillator were so intense that they affected perceptibly a small coil tuned to the twenty-sixth higher tone.

distant "electrical oscillator." This circuit, in responding, however feebly, to the transmitted vibrations, affected magnets and other contrivances, through the medium of which were controlled the movements of the propeller and rudder, and also the operations of numerous other appliances.

By the simple means described the knowledge, experience, judgment—the mind, so to speak—of the distant operator were embodied in that machine, which was thus enabled to move and to perform all its operations with reason and intelligence. It behaved just like a blindfolded person obeying directions received through the ear.

The automatons so far constructed had "borrowed minds," so to speak, as each merely formed part of the distant operator who conveyed to it his intelligent orders; but this art is only in the beginning. I purpose to show that, however impossible it may now seem, an automaton may be contrived which will have its "own mind," and by this I mean that it will be able, independent of any operator, left entirely to itself, to perform, in response to external influences affecting its sensitive organs, a great variety of acts and operations as if it had intelligence. It will be able to follow a course laid out or to obey orders given far in advance; it will be capable of distinguishing between what it ought and what it ought not to do, and of making experiences or, otherwise stated, of recording impressions which will definitely affect its subsequent actions. In fact, I have already conceived such a plan.

Although I evolved this invention many years ago and explained it to my visitors very frequently in my laboratory demonstrations, it was not until much later, long after I had perfected it, that it became known, when, naturally enough, it gave rise to much discussion and to sensational reports. But the true significance of this new art was not grasped by the majority, nor was the great force of the underlying principle recognized. As nearly as I could judge from the numerous comments which then appeared, the results I had obtained were considered as entirely impossible. Even the few who were disposed to admit the practicability of the

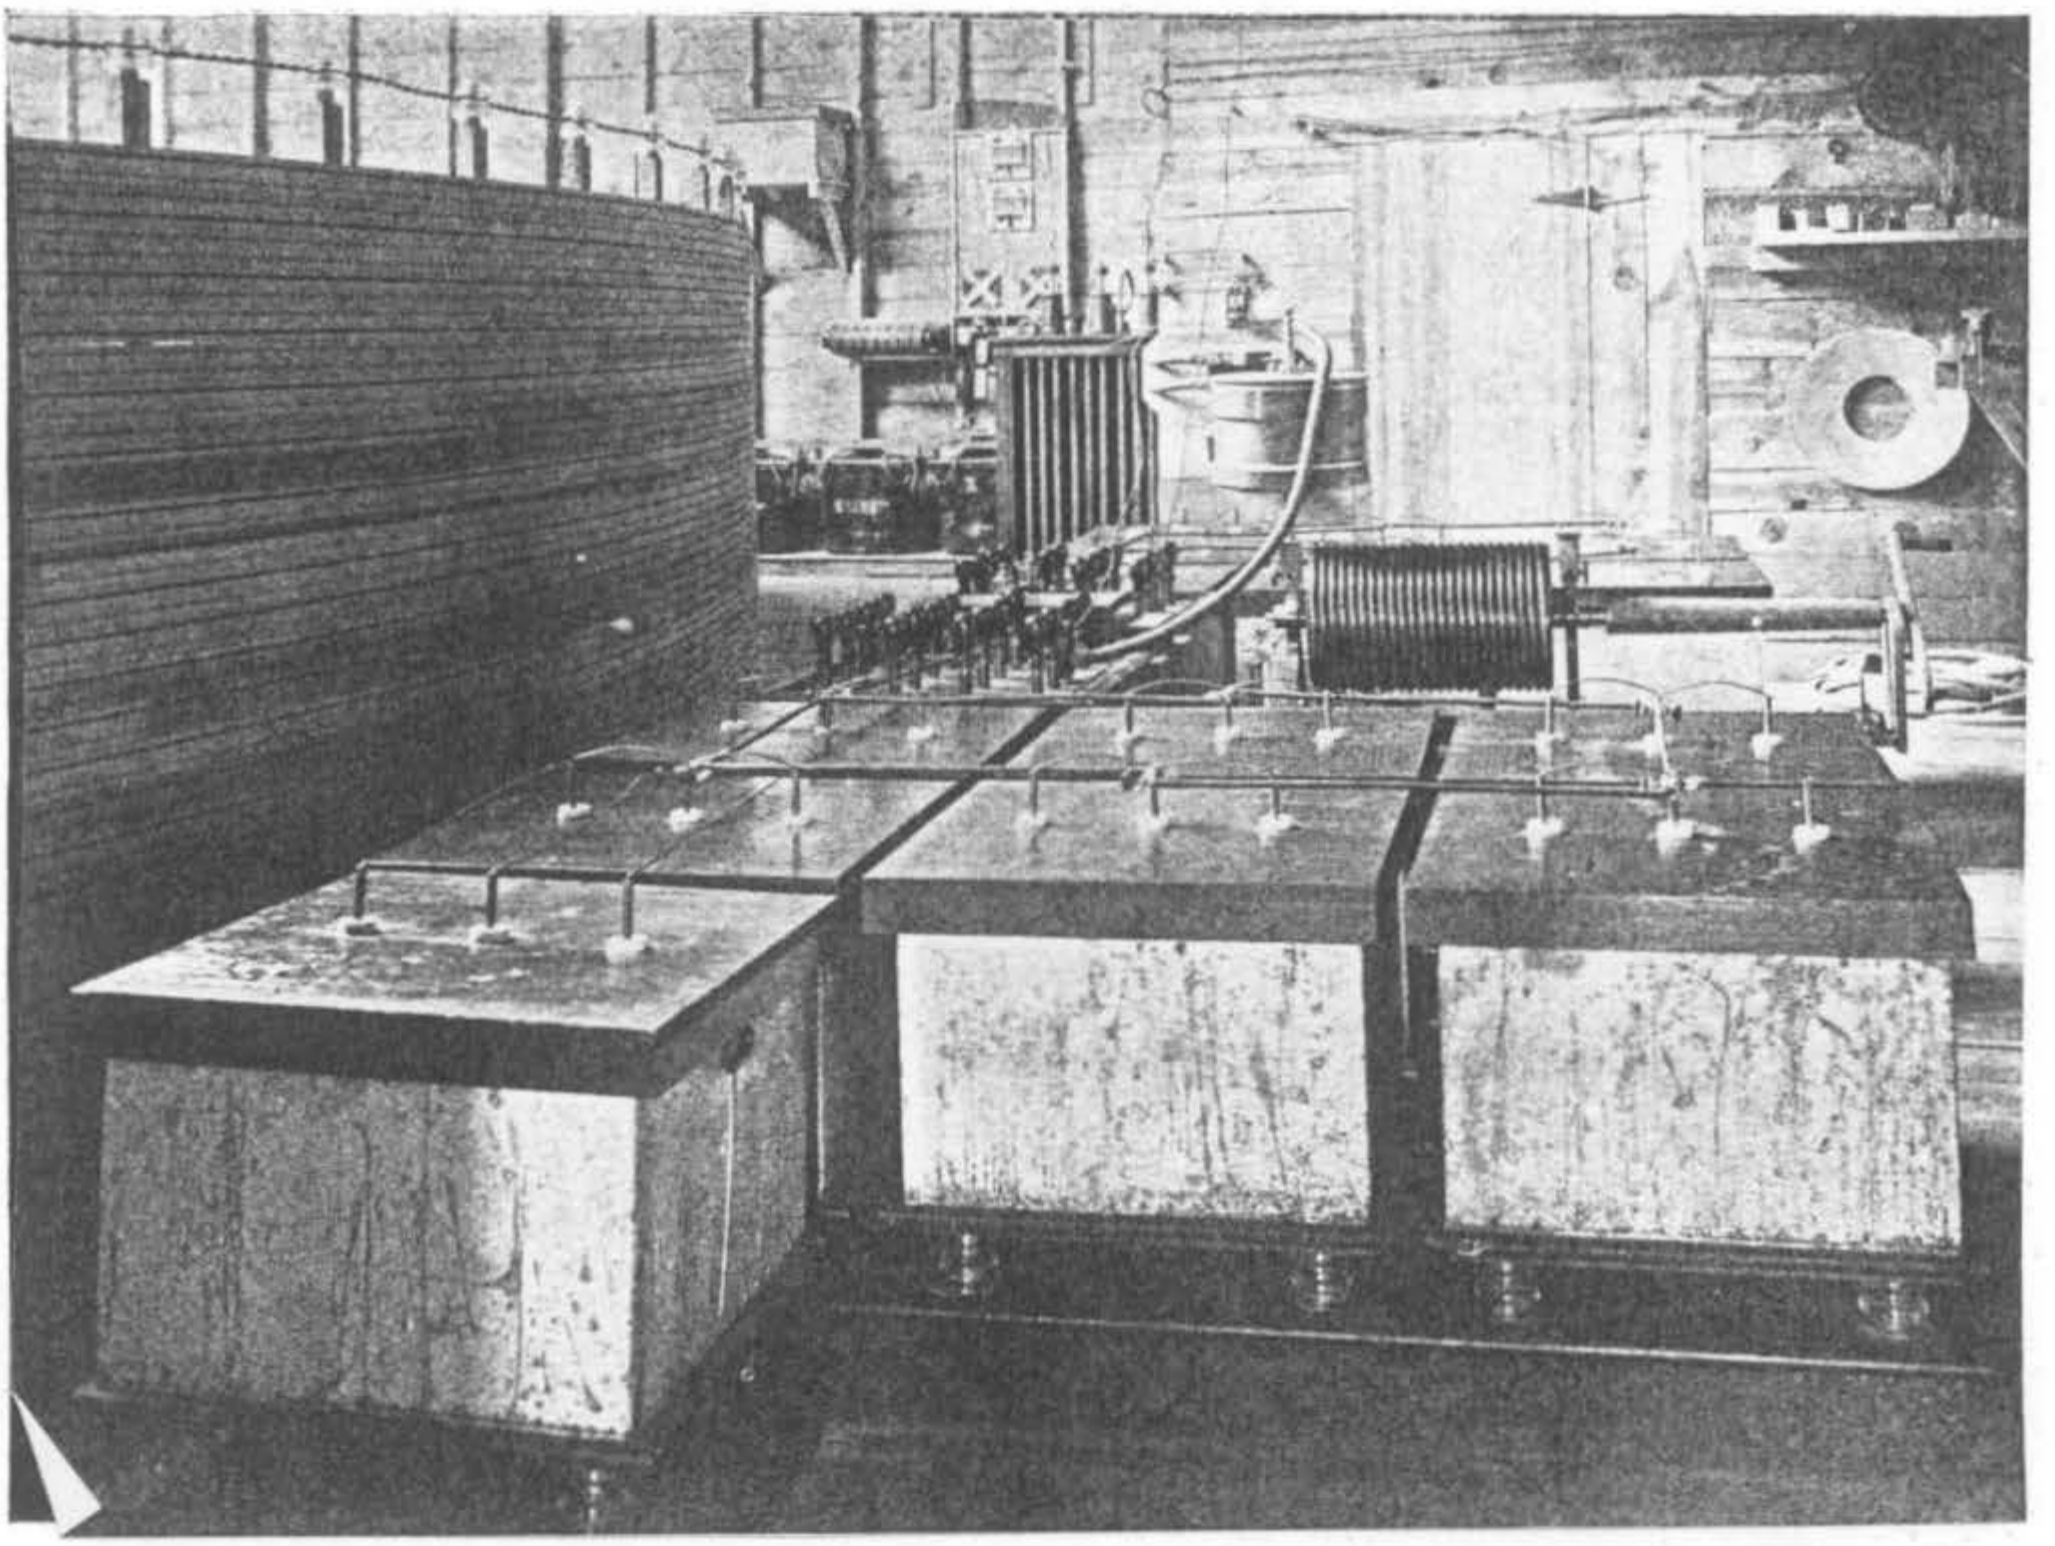

FIG. 6. PHOTOGRAPHIC VIEW OF THE ESSENTIAL PARTS OF THE ELECTRICAL OSCILLATOR USED IN THE EXPERIMENTS DESCRIBED.

invention saw in it merely an automobile torpedo, which was to be used for the purpose of blowing up battle-ships, with doubtful success. The general impression was that I contemplated simply the steering of such a vessel by means of Hertzian or other rays. There are torpedoes steered electrically by wires, and there are means of communicating without wires, and the above was, of course, an obvious inference. Had I accomplished nothing more than this, I should have made a small advance indeed. But the art I have evolved does not contemplate merely the change of direction of a moving vessel; it affords a means of absolutely controlling, in every respect, all the innumerable translatory movements, as well as the operations of all the internal organs, no matter how many, of an individualized automaton. Criticisms to the effect that the control of the automaton could be interfered with were made by people who do not even dream of the wonderful results which can be accomplished by the use of electrical vibrations. The world moves slowly, and new truths are difficult to see. Certainly, by the use of this principle, an arm for attack as well as defense may be provided, of a destructiveness all the greater as the principle is applicable to submarine and aërial vessels. There is virtually no restriction as to the amount of explosive it can carry, or as to the distance at which it can strike, and failure is almost impossible. But the force of this new principle does not wholly reside in its destructiveness. Its advent introduces into warfare an element which never existed before—a fighting-machine without men as a means of attack and defense. The continuous development in this direction must ultimately make war a mere contest of machines without men and without loss of life—a condition which would have been impossible without this new departure, and which, in my opinion, must be reached as preliminary to permanent peace. The future will either bear out or disprove these views. My ideas on this subject have been put forth with deep conviction, but in a humble spirit.

The establishment of permanent peaceful relations between nations would most effectively reduce the force retarding the human mass, and would be the best solution of this great human problem. But will the dream of universal peace ever be realized? Let us hope that it will. When all darkness shall be dissipated by the light of science, when all nations shall be merged into one, and

patriotism shall be identical with religion, when there shall be one language, one country, one end, then the dream will have become reality.

THE THIRD PROBLEM: HOW TO INCREASE THE FORCE ACCELERATING THE HUMAN MASS—THE HARNESSING OF THE SUN'S ENERGY.

Of the three possible solutions of the main problem of increasing human energy, this is by far the most important to consider, not only because of its intrinsic significance, but also because of its intimate bearing on all the many elements and conditions which determine the movement of humanity. In order to proceed systematically, it would be necessary for me to dwell on all those considerations which have guided me from the outset in my efforts to arrive at a solution, and which have led me, step by step, to the results I shall now describe. As a preliminary study of the problem an analytical investigation, such as I have made, of the chief forces which determine the onward movement, would be of advantage, particularly in conveying an idea of that hypothetical "velocity" which, as explained in the beginning, is a measure of human energy; but to deal with this specifically here, as I would desire, would lead me far beyond the scope of the present subject. Suffice it to state that the resultant of all these forces is always in the direction of reason, which, therefore, determines, at any time, the direction of human movement. This is to say that every effort which is scientifically applied, rational, useful, or practical, must be in the direction in which the mass is moving. The practical, rational man, the observer, the man of business, he who reasons, calculates, or determines in advance, carefully applies his effort so that when coming into effect it will be in the direction of the movement, making it thus most efficient, and in this knowledge and ability lies the secret of his success. Every new fact discovered, every new experience or new element added to our knowledge and entering into the domain of reason, affects the same and, therefore, changes

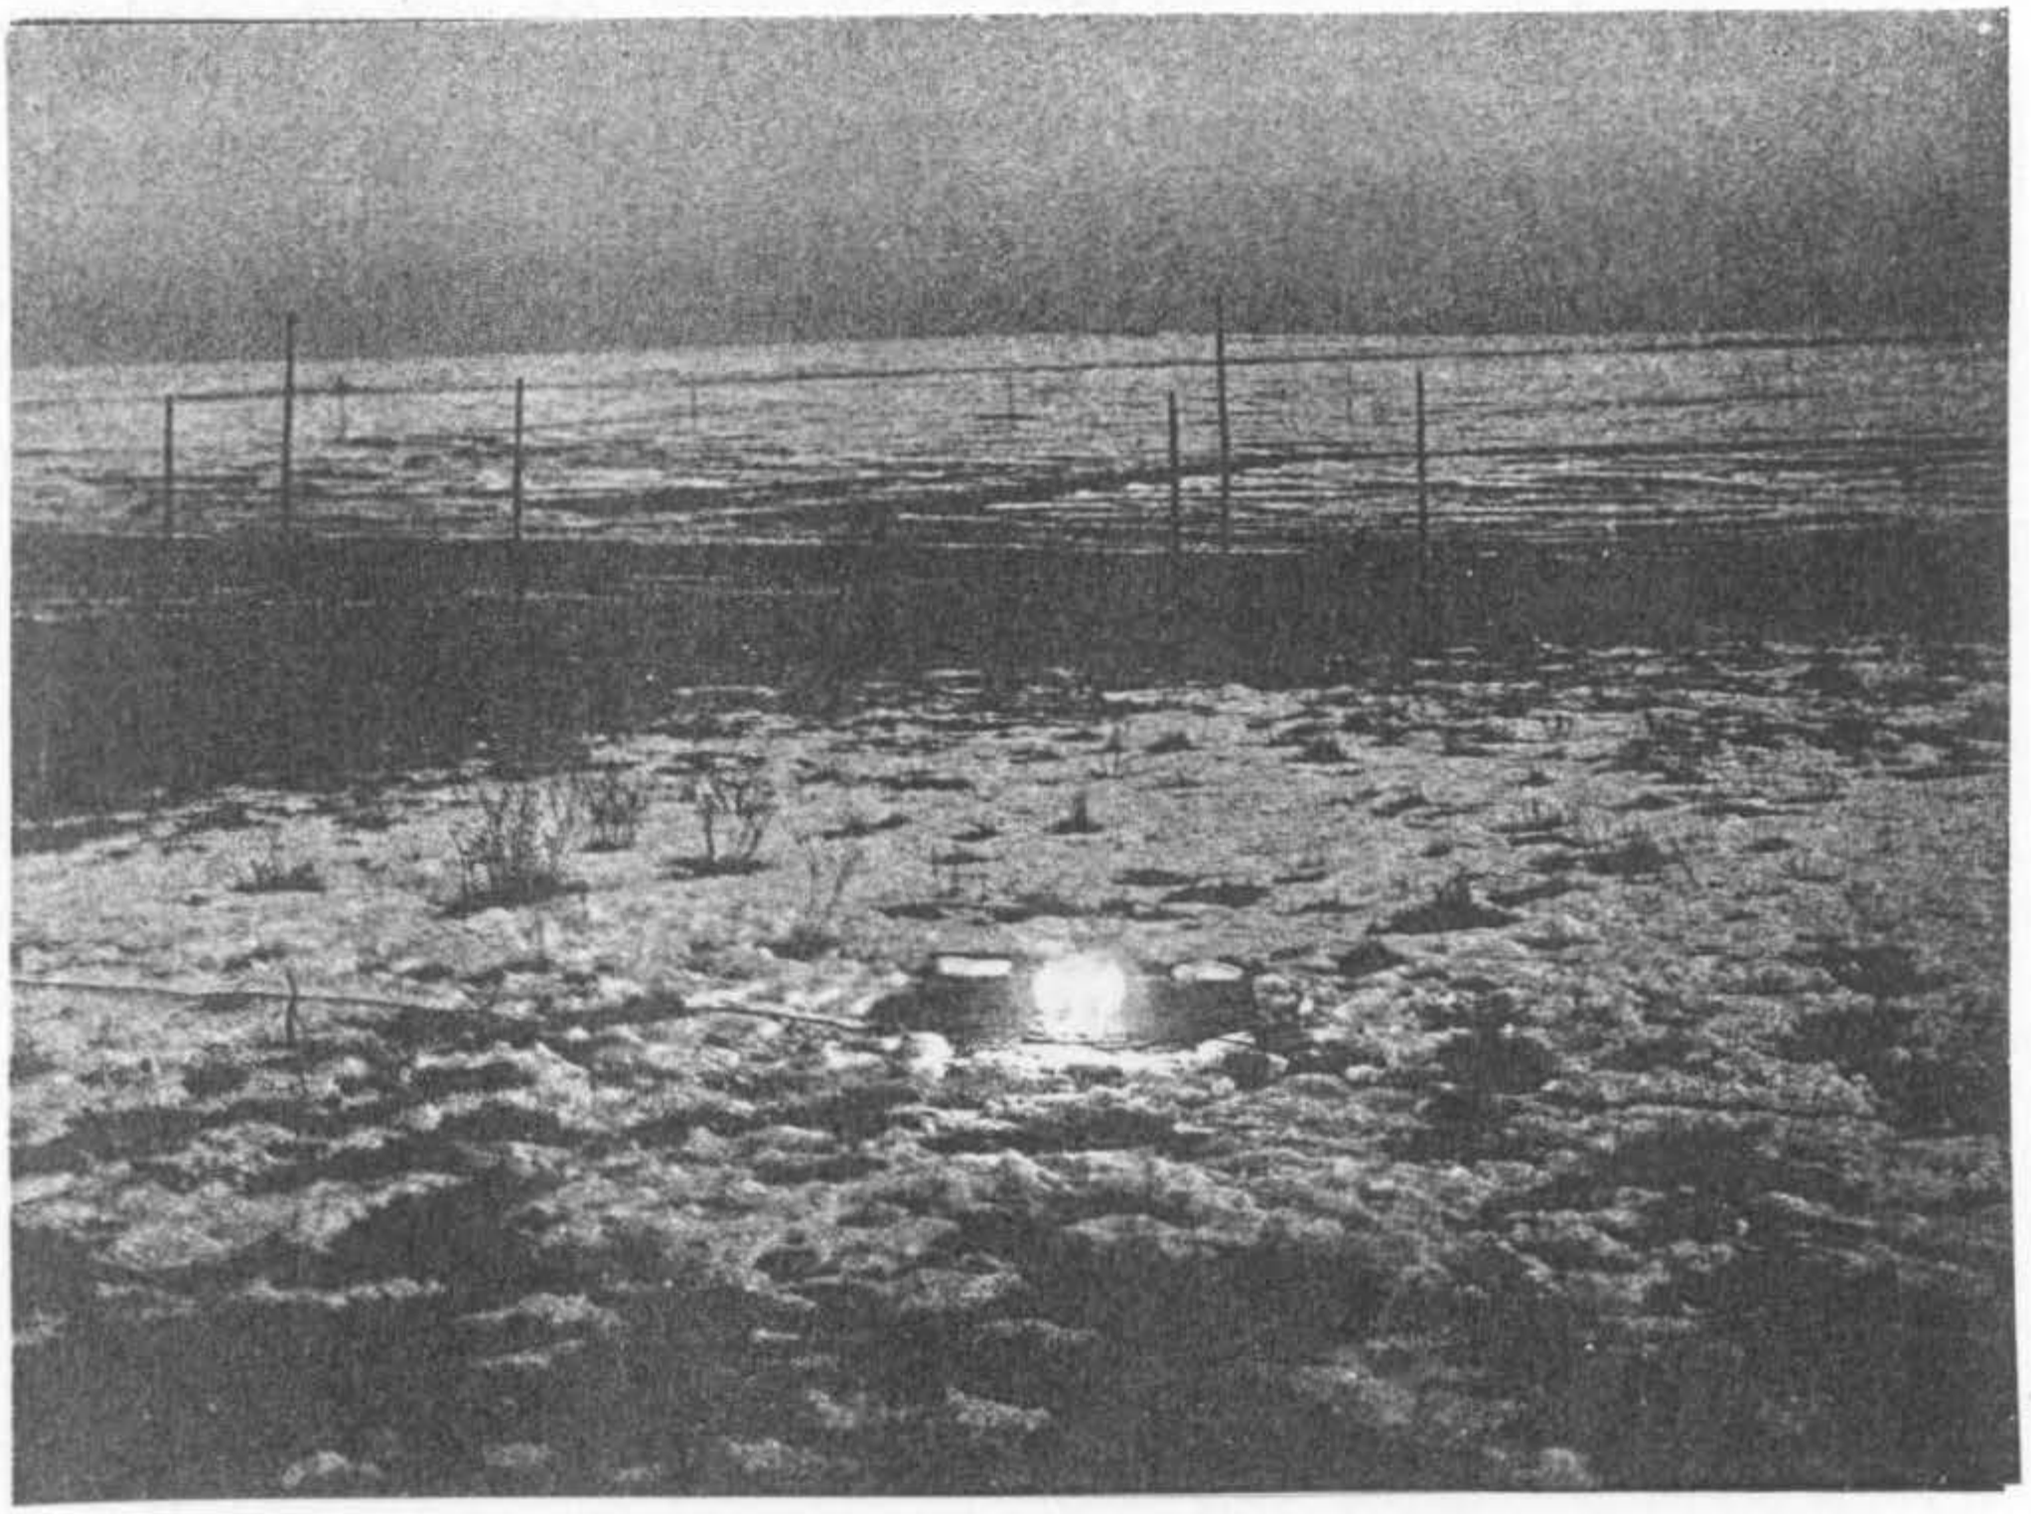

FIG. 7. EXPERIMENT TO ILLUSTRATE AN INDUCTIVE EFFECT OF AN ELECTRICAL OSCILLATOR OF GREAT POWER.

The photograph shows three ordinary incandescent lamps lighted to full candle-power by currents induced in a local loop consisting of a single wire forming a square of fifty feet each side, which includes the lamps, and which is at a distance of one hundred feet from the primary circuit energized by the oscillator. The loop likewise includes an electrical condenser, and is exactly attuned to the vibrations of the oscillator, which is worked at less than five per cent. of its total capacity.

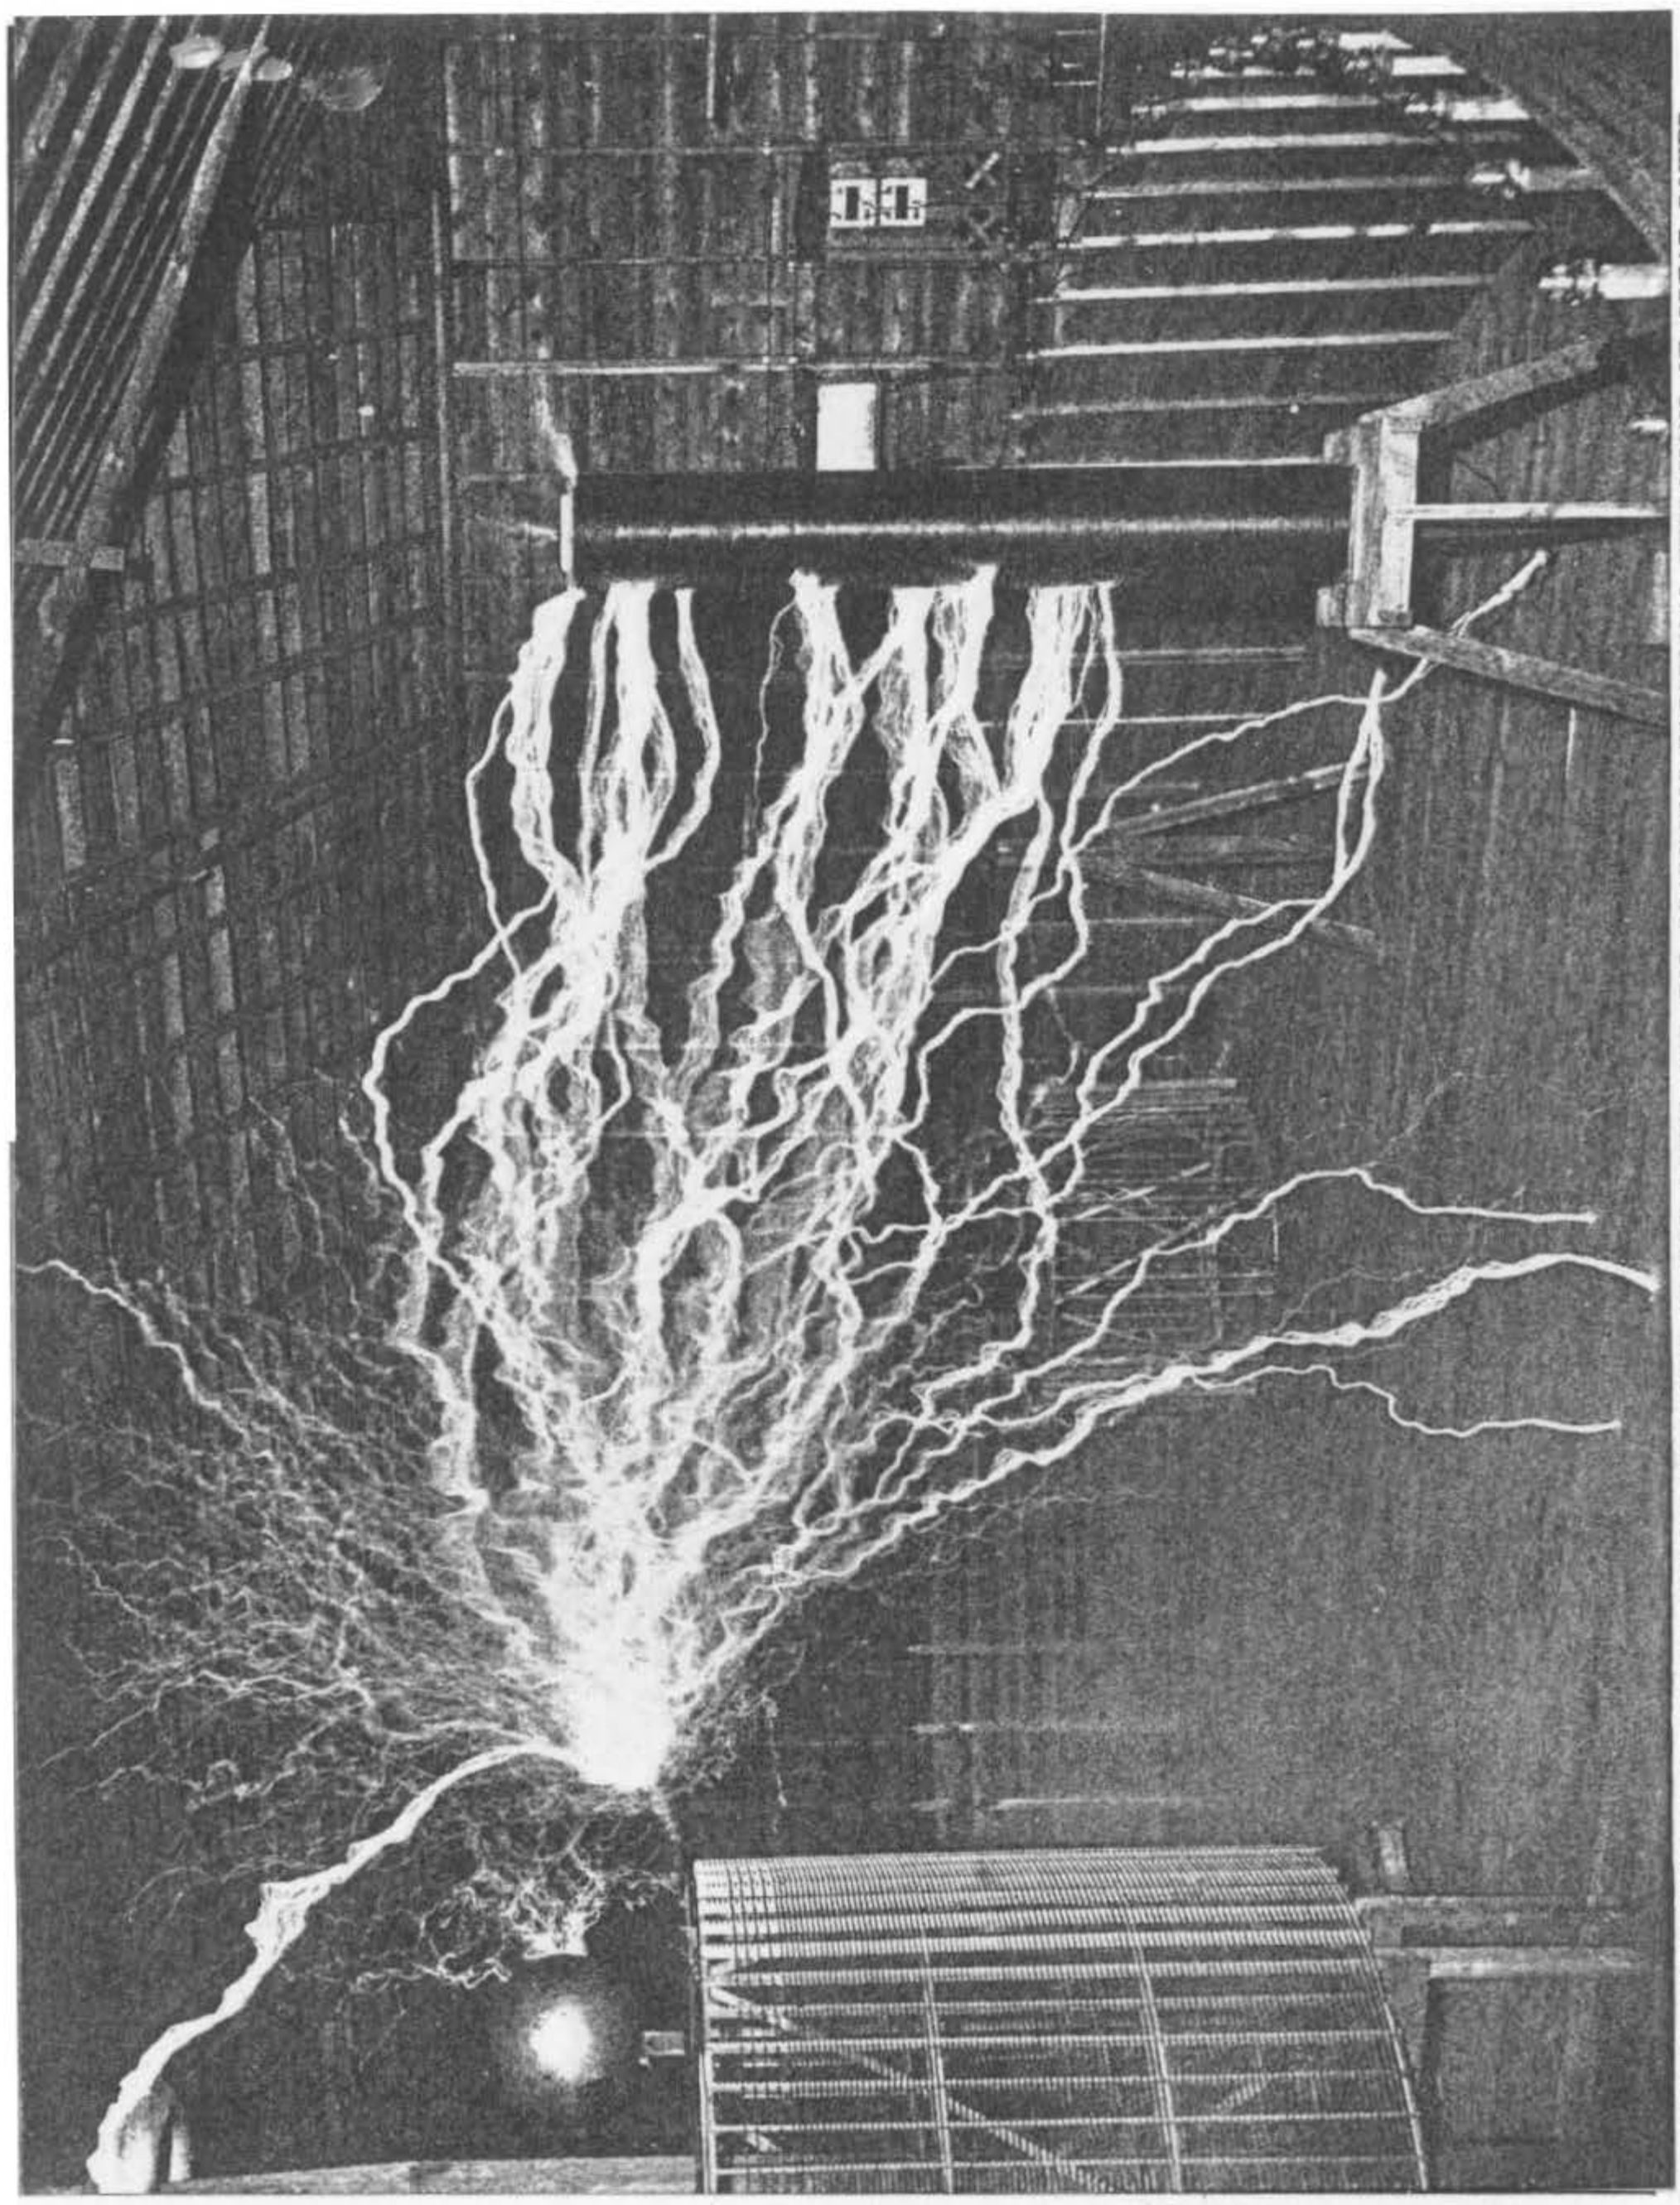

FIG. 8. EXPERIMENT TO ILLUSTRATE THE CAPACITY OF THE OSCILLATOR FOR PRODUCING ELECTRICAL EXPLOSIONS OF GREAT POWER.

NOTE TO FIG. 8.—The coil, partly shown in the photograph, creates an alternative movement of electricity from the earth into a large reservoir and back at the rate of one hundred thousand alternations per second. The adjustments are such that the reservoir is filled full and bursts at each alternation just at the moment when the electrical pressure reaches the maximum. The discharge escapes with a deafening noise, striking an unconnected coil twenty-two feet away, and creating such a commotion of electricity in the earth that sparks an inch long can be drawn from a water-main at a distance of three hundred feet from the laboratory.

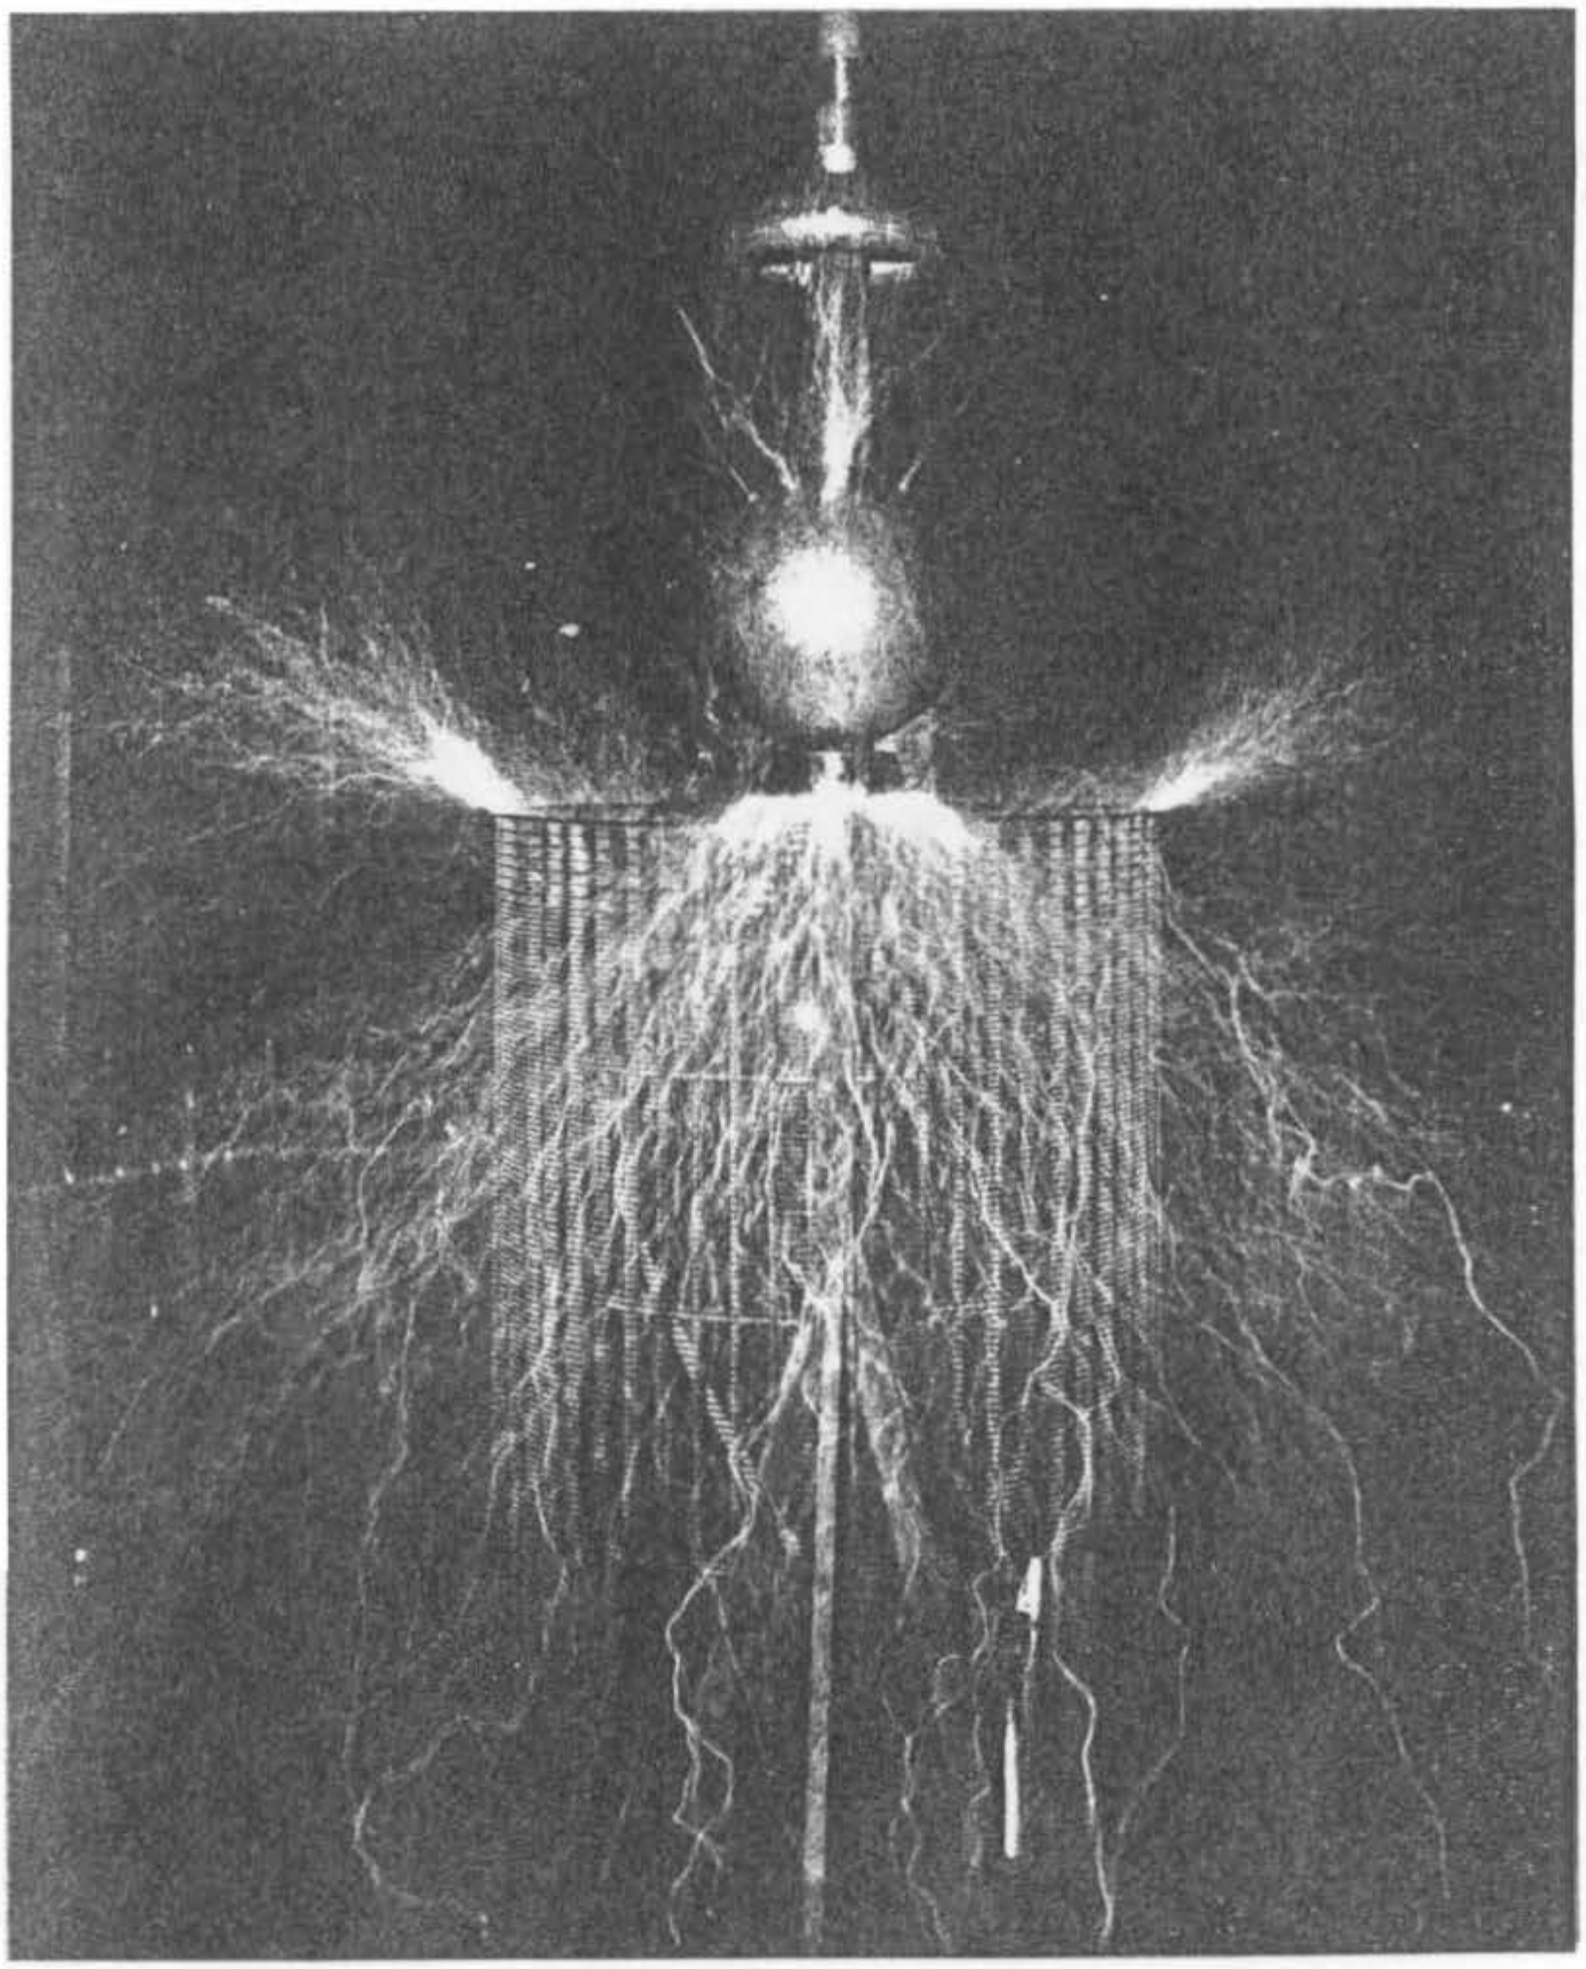

FIG. 9. EXPERIMENT TO ILLUSTRATE THE CAPACITY OF THE OSCILLATOR FOR CREATING A GREAT ELECTRICAL MOVEMENT.

The ball shown in the photograph, covered with a polished metallic coating of twenty square feet of surface, represents a large reservoir of electricity, and the inverted tin pan underneath, with a sharp rim, a big opening through which the electricity can escape before filling the reservoir. The quantity of electricity set in movement is so great that, although most of it escapes through the rim of the pan or opening provided, the ball or reservoir is nevertheless alternately emptied and filled to overflowing (as is evident from the discharge escaping on the top of the ball) one hundred and fifty thousand times per second.

the direction of the movement, which, however, must always take place along the resultant of all those efforts which, at that time, we designate as reasonable, that is, self-preserving, useful, profitable, or practical. These efforts concern our daily life, our necessities and comforts, our work and business, and it is these which drive man onward.

But looking at all this busy world about us, on all this complex mass as it daily throbs and moves, what is it but an immense clockwork driven by a spring? In the morning, when we rise, we cannot fail to note that all the objects about us are manufactured by machinery: the water we use is lifted by steam-power; the trains bring our breakfast from distant localities; the elevators in our dwelling and in our office building, the cars that carry us there, are all driven by power; in all our daily errands, and in our very life-pursuit, we depend upon it; all the objects we see tell us of it; and when we return to our machine-made dwelling at night, lest we should forget it, all the material comforts of our home, our cheering stove and lamp, remind us how much we depend on power. And when there is an accidental stoppage of the machinery, when the city is snow-bound, or the life-sustaining movement otherwise temporarily arrested, we are affrighted to realize

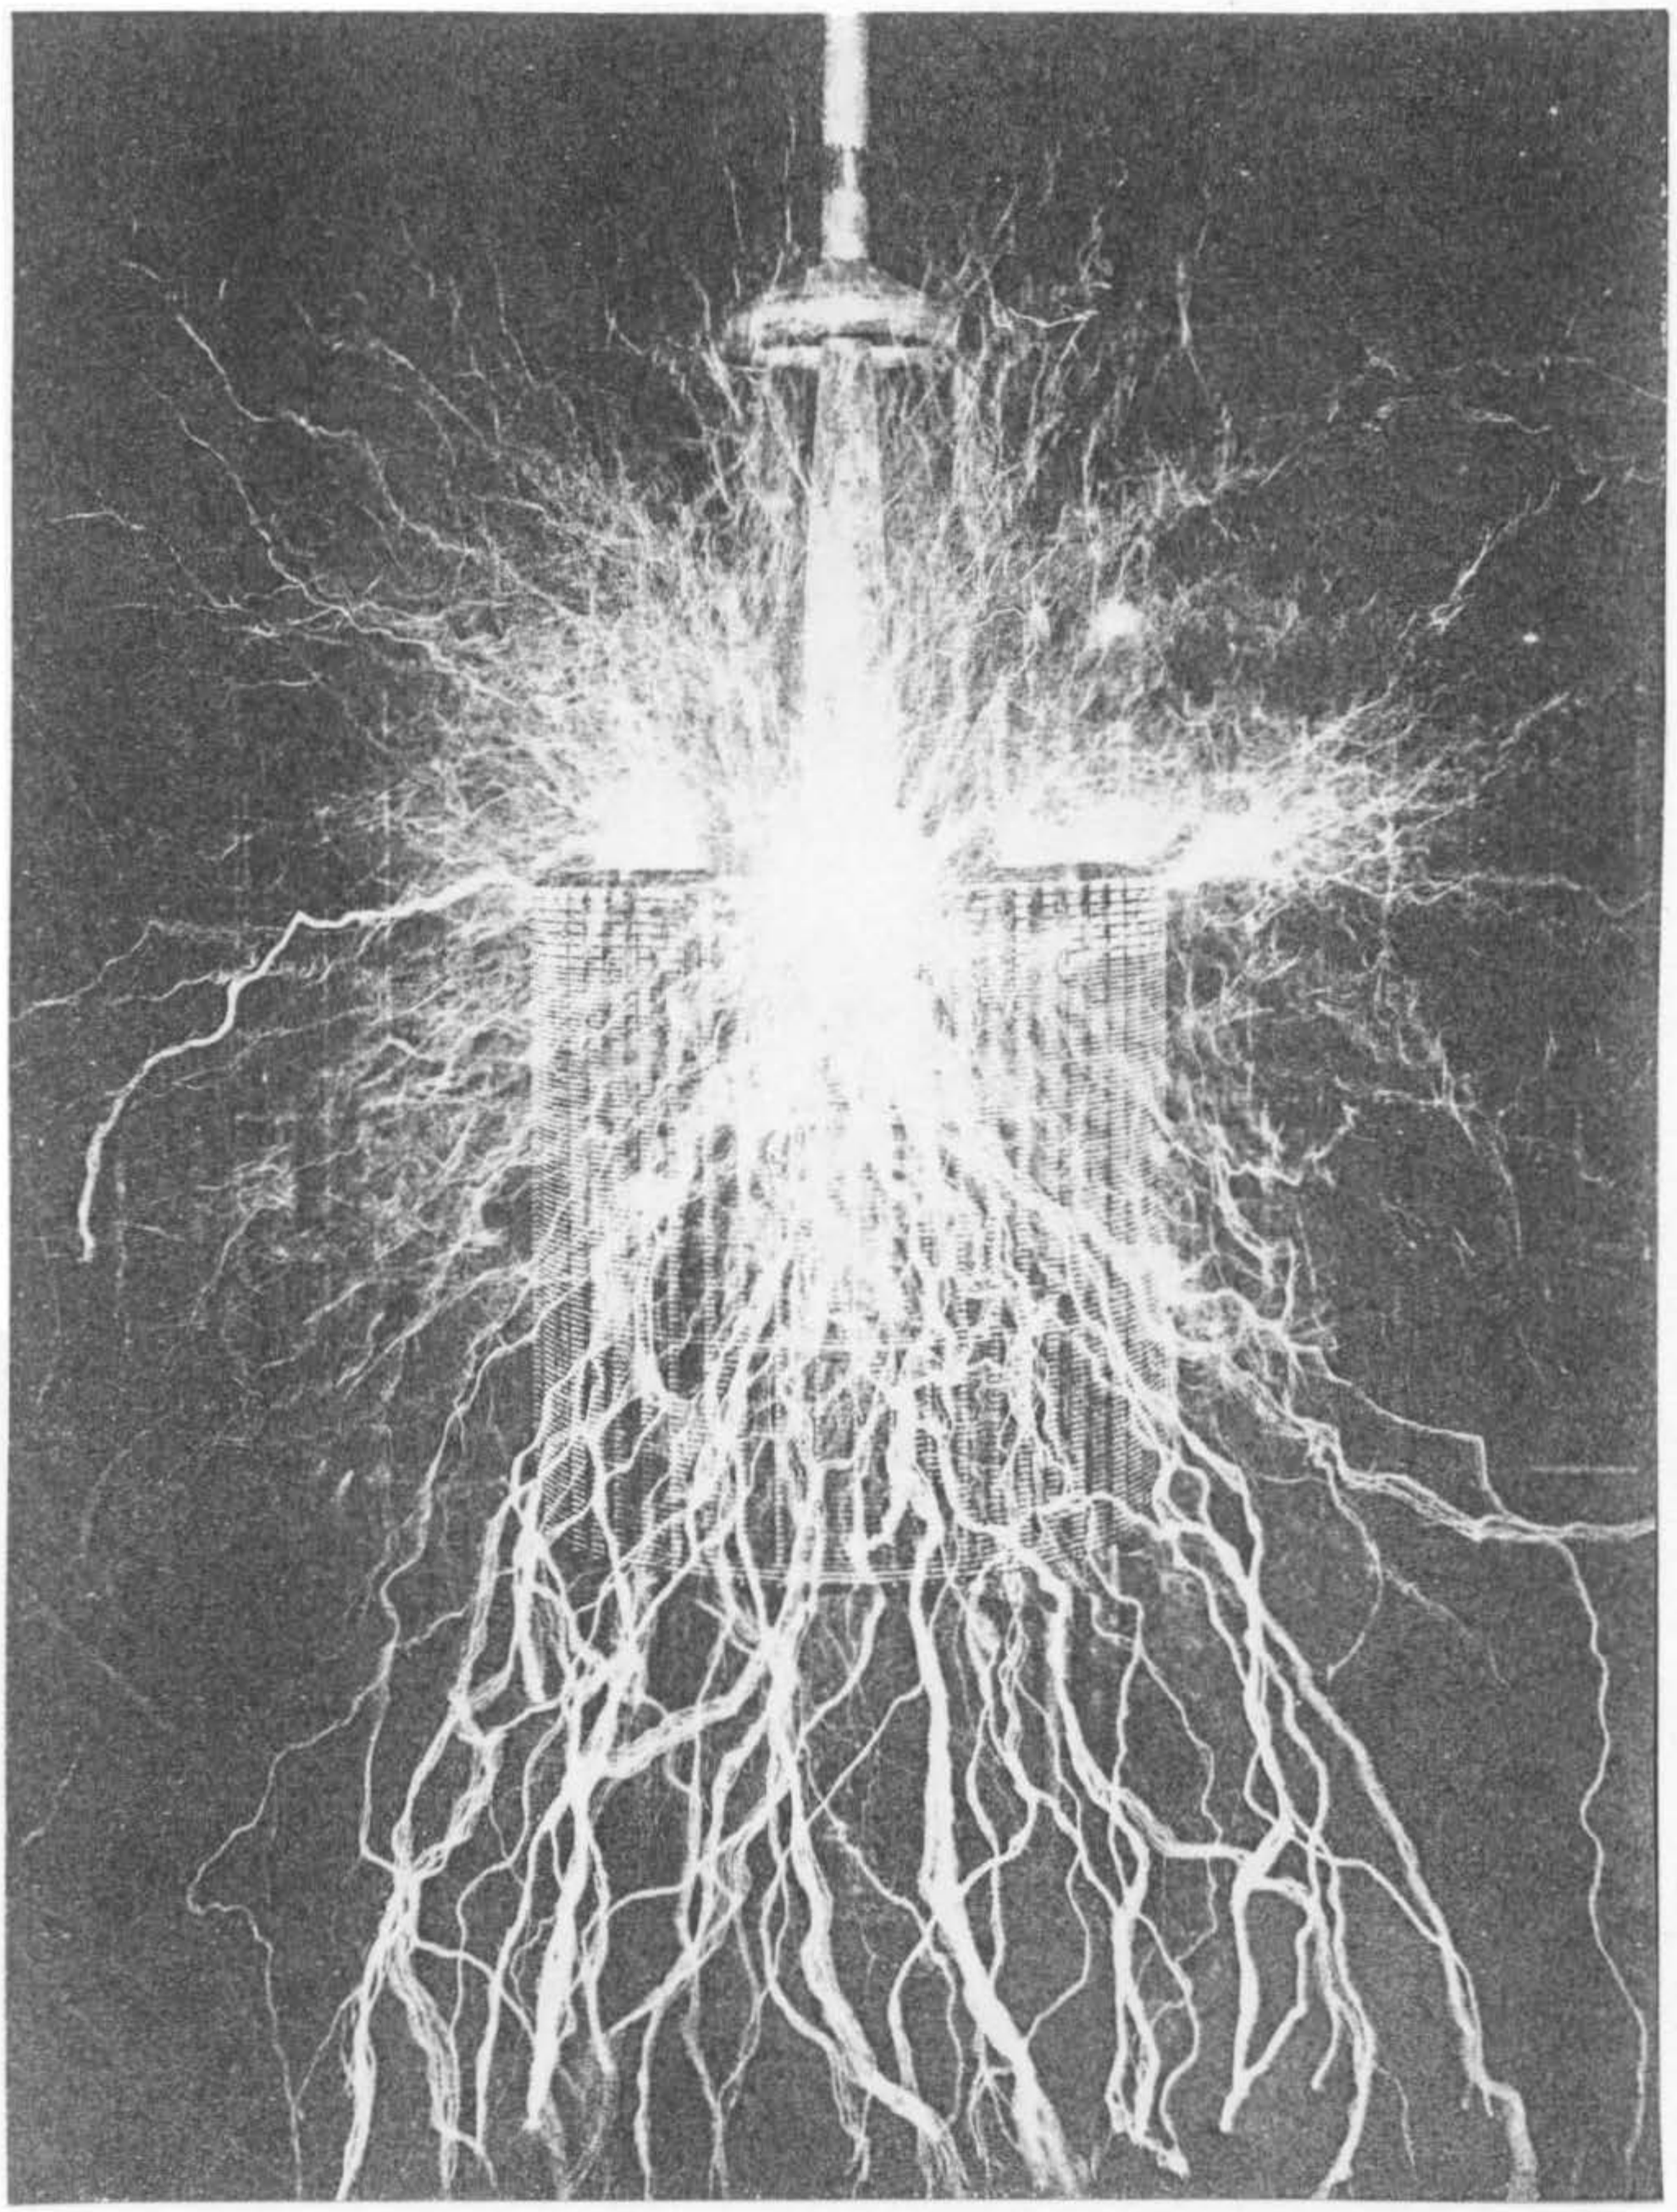

FIG. 10. PHOTOGRAPHIC VIEW OF AN EXPERIMENT TO ILLUSTRATE AN EFFECT OF AN ELECTRICAL OSCILLATOR DELIVERING ENERGY AT A RATE OF SEVENTY-FIVE THOUSAND HORSE-POWER.

The discharge, creating a strong draft owing to the heating of the air, is carried upward through the open roof of the building. The greatest width across is nearly seventy feet. The pressure is over twelve million volts, and the current alternates one hundred and thirty thousand times per second.

how impossible it would be for us to live the life we live without motive power. Motive power means work. To increase the force accelerating human movement means, therefore, to perform more work.

So we find that the three possible solutions of the great problem of increasing human energy are answered by the three words: *food*, *peace*, *work*. Many a year I have thought and pondered, lost myself in

speculations and theories, considering man as a mass moved by a force, viewing his inexplicable movement in the light of a mechanical one, and applying the simple principles of mechanics to the analysis of the same until I arrived at these solutions, only to realize that they were taught to me in my early childhood. These three words sound the key-notes of the Christian religion. Their scientific meaning and purpose are now clear to me: food to increase the mass, peace to diminish the retarding force, and work to increase the force accelerating human movement. These are the only three solutions which are possible of that great problem, and all of them have one object, one end, namely, to increase human energy. When we recognize this, we cannot help wondering how profoundly wise and scientific and how immensely practical the Christian religion is, and in what a marked contrast it stands in this respect to other religions. It is unmistakably the result of practical experiment and scientific observation which have extended through ages, while other religions seem to be the outcome of merely abstract reasoning. Work, untiring effort, useful and accumulative, with periods of rest and recuperation aiming at higher efficiency, is its chief and ever-recurring command. Thus we are inspired both by Christianity and Science to do our utmost toward increasing the performance of mankind. This most important of human problems I shall now specifically consider.

THE SOURCE OF HUMAN ENERGY—THE THREE WAYS OF DRAWING ENERGY FROM THE SUN.

FIRST let us ask: Whence comes all the motive power? What is the spring that drives all? We see the ocean rise and fall, the rivers flow, the wind, rain, hail, and snow beat on our windows, the trains and steamers come and go; we hear the rattling noise of carriages, the voices from the street; we feel, smell, and taste; and we think of all this. And all this movement, from the surging of the mighty ocean to that subtle movement concerned in our thought, has but one common cause. All this energy emanates from one single center, one single source—the sun. The sun is the spring that drives all. The sun maintains all human life and supplies all human energy. Another answer we have now found to the above great question: To increase the force accelerating human movement means to turn to the uses of man more of the sun's energy. We honor and revere those great men of bygone times whose names are linked with immortal achievements, who have proved themselves benefactors of humanity—the religious reformer with his wise maxims of life, the philosopher with his deep truths, the mathematician with his formulæ, the physicist with his laws, the discoverer with his principles and secrets wrested from nature, the artist with his forms of the beautiful; but who honors him, the greatest of all,—who can tell the name of him,—who first turned to use the sun's energy to save the effort of a weak fellow-creature? That was man's first act of scientific philanthropy, and its consequences have been incalculable.

From the very beginning three ways of drawing energy from the sun were open to man. The savage, when he warmed his frozen limbs at a fire kindled in some way, availed himself of the energy of the sun stored in the burning material. When he carried a bundle of branches to his cave and burned them there, he made use of the sun's stored energy transported from one to another locality. When he set sail to his canoe, he utilized the energy of the sun supplied to the atmosphere or ambient medium. There can be no doubt that the first is the oldest way. A fire, found accidentally, taught the savage to appreciate its beneficial heat. He then very likely conceived the idea of carrying the glowing embers to his abode. Finally he learned to use the force of a swift current of water or air. It is characteristic of modern development that progress has been effected in the same order. The utilization of the energy stored in wood or coal, or, generally speaking, fuel, led to the steam-engine. Next a great stride in advance was made in energy-transportation by the use of electricity, which permitted the transfer of energy from one locality to another without transporting the material. But as to the utilization of the energy of the ambient medium, no radical step forward has as yet been made known.

The ultimate results of development in these three directions are: first, the burning of coal by a cold process in a battery; second, the efficient utilization of the energy of the ambient medium; and, third, the transmission without wires of electrical energy to any distance. In whatever way these results may be arrived at, their practical application will necessarily involve an extensive use of iron, and this invaluable metal will undoubtedly be an essential element in the further de-

velopment along these three lines. If we succeed in burning coal by a cold process and thus obtaining electrical energy in an efficient and inexpensive manner, we shall require in many practical uses of this energy electric motors—that is, iron. If we are successful in deriving energy from the ambient medium, we shall need, both in the obtainment and utilization of the energy, machinery—again, iron. If we realize the transmission of electrical energy without wires on an industrial scale, we shall be compelled to use extensively electric generators—once more, iron. Whatever we may do, iron will probably be the chief means of accomplishment in the near future, possibly more so than in the past. How long its reign will last is difficult to tell, for even now aluminium is looming up as a threatening competitor. But for the time being, next to providing new resources of energy, it is of the greatest importance to make improvements in the manufacture and utilization of iron. Great advances are possible in these latter directions, which, if brought about, would enormously increase the useful performance of mankind.

GREAT POSSIBILITIES OFFERED BY IRON FOR INCREASING HUMAN PERFORMANCE—ENORMOUS WASTE IN IRON MANUFACTURE.

IRON is by far the most important factor in modern progress. It contributes more than any other industrial product to the force accelerating human movement. So general is the use of this metal, and so intimately is it connected with all that concerns our life, that it has become as indispensable to us as the very air we breathe. Its name is synonymous with usefulness. But, however great the influence of iron may be on the present human development, it does not add to the force urging man onward nearly as much as it might. First of all, its manufacture as now carried on is connected with an appalling waste of fuel—that is, waste of energy. Then, again, only a part of all the iron produced is applied for useful purposes. A good part of it goes to create frictional resistances, while still another large part is the means of developing negative forces greatly retarding human movement. Thus the negative force of war is almost wholly represented in iron. It is impossible to estimate with any degree of accuracy the magnitude of this greatest of all retarding forces, but it is certainly very considerable. If the present positive impelling force due to all useful applications of iron be represented by ten, for instance, I should not think it exaggeration to estimate the negative force of war, with due consideration of all its retarding influences and results, at, say, six. On the basis of this estimate the effective impelling force of iron in the positive direction would be measured by the difference of these two numbers, which is four. But if, through the establishment of universal peace, the manufacture of war machinery should cease, and all struggle for supremacy between nations should be turned into healthful, ever active and productive commercial competition, then the positive impelling force due to iron would be measured by the sum of those two numbers, which is sixteen—that is, this force would have four times its present value. This example is, of course, merely intended to give an idea of the immense increase in the useful performance of mankind which would result from a radical reform of the iron industries supplying the implements of warfare.

A similar inestimable advantage in the saving of energy available to man would be secured by obviating the great waste of coal which is inseparably connected with the present methods of manufacturing iron. In some countries, as in Great Britain, the hurtful effects of this squandering of fuel are beginning to be felt. The price of coal is constantly rising, and the poor are made to suffer more and more. Though we are still far from the dreaded "exhaustion of the coal-fields," philanthropy commands us to invent novel methods of manufacturing iron, which will not involve such barbarous waste of this valuable material from which we derive at present most of our energy. It is our duty to coming generations to leave this store of energy intact for them, or at least not to touch it until we shall have perfected processes for burning coal more efficiently. Those who are to come after us will need fuel more than we do. We should be able to manufacture the iron we require by using the sun's energy, without wasting any coal at all. As an effort to this end the idea of smelting iron ores by electric currents obtained from the energy of falling water has naturally suggested itself to many. I have myself spent much time in endeavoring to evolve such a practical process, which would enable iron to be manufactured at small cost. After a prolonged investigation of the subject, finding that it was unprofitable to use the currents generated directly for smelting the ore, I devised a method which is far more economical.

ECONOMICAL PRODUCTION OF IRON BY A NEW PROCESS.

THE industrial project, as I worked it out six years ago, contemplated the employment of the electric currents derived from the energy of a waterfall, not directly for smelting the ore, but for decomposing water, as a preliminary step. To lessen the cost of the plant, I proposed to generate the currents in exceptionally cheap and simple dynamos, which I designed for this sole purpose. The hydrogen liberated in the electrolytic decomposition was to be burned or recombined with oxygen, not with that from which it was separated, but with that of the atmosphere. Thus very nearly the total electrical energy used up in the decomposition of the water would be recovered in the form of heat resulting from the recombination of the hydrogen. This heat was to be applied to the smelting of the ore. The oxygen gained as a by-product in the decomposition of the water I intended to use for certain other industrial purposes, which would probably yield good financial returns, inasmuch as this is the cheapest way of obtaining this gas in large quantities. In any event, it could be employed to burn all kinds of refuse, cheap hydrocarbon, or coal of the most inferior quality which could not be burned in air or be otherwise utilized to advantage, and thus again a considerable amount of heat would be made available for the smelting of the ore. To increase the economy of the process I contemplated, furthermore, using an arrangement such that the hot metal and the products of combustion, coming out of the furnace, would give up their heat upon the cold ore going into the furnace, so that comparatively little of the heat-energy would be lost in the smelting. I calculated that probably forty thousand pounds of iron could be produced per horse-power per annum by this method. Liberal allowances were made for those losses which are unavoidable, the above quantity being about half of that theoretically obtainable. Relying on this estimate and on practical data with reference to a certain kind of sand ore existing in abundance in the region of the Great Lakes, including cost of transportation and labor, I found that in some localities iron could be manufactured in this manner cheaper than by any of the adopted methods. This result would be attained all the more surely if the oxygen obtained from the water, instead of being used for smelting the ore, as assumed, should be more profitably employed. Any new demand for this gas would secure a higher revenue from the plant, thus cheapening the iron. This project was advanced merely in the interest of industry. Some day, I hope, a beautiful industrial butterfly will come out of the dusty and shriveled chrysalis.

The production of iron from sand ores by a process of magnetic separation is highly commendable in principle, since it involves no waste of coal; but the usefulness of this method is largely reduced by the necessity of melting the iron afterward. As to the crushing of iron ore, I would consider it rational only if done by water-power, or by energy otherwise obtained without consumption of fuel. An electrolytic cold process, which would make it possible to extract iron cheaply, and also to mold it into the required forms without any fuel consumption, would, in my opinion, be a very great advance in iron manufacture. In common with some other metals, iron has so far resisted electrolytic treatment, but there can be no doubt that such a cold process will ultimately replace in metallurgy the present crude method of casting, and thus obviate the enormous waste of fuel necessitated by the repeated heating of metal in the foundries.

Up to a few decades ago the usefulness of iron was based almost wholly on its remarkable mechanical properties, but since the advent of the commercial dynamo and electric motor its value to mankind has been greatly increased by its unique magnetic qualities. As regards the latter, iron has been greatly improved of late. The signal progress began about thirteen years ago, when I discovered that in using soft Bessemer steel instead of wrought iron, as then customary, in an alternating motor, the performance of the machine was doubled. I brought this fact to the attention of Mr. Albert Schmid, to whose untiring efforts and ability is largely due the supremacy of American electrical machinery, and who was then superintendent of an industrial corporation engaged in this field. Following my suggestion, he constructed transformers of steel, and they showed the same marked improvement. The investigation was then systematically continued under Mr. Schmid's guidance, the impurities being gradually eliminated from the "steel" (which was only such in name, for in reality it was pure soft iron), and soon a product resulted which admitted of little further improvement.

THE COMING AGE OF ALUMINIUM—DOOM OF THE COPPER INDUSTRY—THE GREAT CIVILIZING POTENCY OF THE NEW METAL.

WITH the advances made in iron of late years we have arrived virtually at the limits of improvement. We cannot hope to increase very materially its tensile strength, elasticity, hardness, or malleability, nor can we expect to make it much better as regards its magnetic qualities. More recently a notable gain was secured by the mixture of a small percentage of nickel with the iron, but there is not much room for further advance in this direction. New discoveries may be expected, but they cannot greatly add to the valuable properties of the metal, though they may considerably reduce the cost of manufacture. The immediate future of iron is assured by its cheapness and its unrivaled mechanical and magnetic qualities. These are such that no other product can compete with it now. But there can be no doubt that, at a time not very distant, iron, in many of its now uncontested domains, will have to pass the scepter to another: the coming age will be the age of aluminium. It is only seventy years since this wonderful metal was discovered by Woehler, and the aluminium industry, scarcely forty years old, commands already the attention of the entire world. Such rapid growth has not been recorded in the history of civilization before. Not long ago aluminium was sold at the fanciful price of thirty or forty dollars per pound; to-day it can be had in any desired amount for as many cents. What is more, the time is not far off when this price, too, will be considered fanciful, for great improvements are possible in the methods of its manufacture. Most of the metal is now produced in the electric furnace by a process combining fusion and electrolysis, which offers a number of advantageous features, but involves naturally a great waste of the electrical energy of the current. My estimates show that the price of aluminium could be considerably reduced by adopting in its manufacture a method similar to that proposed by me for the production of iron. A pound of aluminium requires for fusion only about seventy per cent. of the heat needed for melting a pound of iron, and inasmuch as its weight is only about one third of that of the latter, a volume of aluminium four times that of iron could be obtained from a given amount of heat-energy. But a cold electrolytic process of manufacture is the ideal solution, and on this I have placed my hope.

The absolutely unavoidable consequence of the advance of the aluminium industry will be the annihilation of the copper industry. They cannot exist and prosper together, and the latter is doomed beyond any hope of recovery. Even now it is cheaper to convey an electric current through aluminium wires than through copper wires; aluminium castings cost less, and in many domestic and other uses copper has no chance of successfully competing. A further material reduction of the price of aluminium cannot but be fatal to copper. But the progress of the former will not go on unchecked, for, as it ever happens in such cases, the larger industry will absorb the smaller one: the giant copper interests will control the pygmy aluminium interests, and the slow-pacing copper will reduce the lively gait of aluminium. This will only delay, not avoid, the impending catastrophe.

Aluminium, however, will not stop at downing copper. Before many years have passed it will be engaged in a fierce struggle with iron, and in the latter it will find an adversary not easy to conquer. The issue of the contest will largely depend on whether iron shall be indispensable in electric machinery. This the future alone can decide. The magnetism as exhibited in iron is an isolated phenomenon in nature. What it is that makes this metal behave so radically different from all other materials in this respect has not yet been ascertained, though many theories have been suggested. As regards magnetism, the molecules of the various bodies behave like hollow beams partly filled with a heavy fluid and balanced in the middle in the manner of a see-saw. Evidently some disturbing influence exists in nature which causes each molecule, like such a beam, to tilt either one or the other way. If the molecules are tilted one way, the body is magnetic; if they are tilted the other way, the body is non-magnetic; but both positions are stable, as they would be in the case of the hollow beam, owing to the rushing of the fluid to the lower end. Now, the wonderful thing is that the molecules of all known bodies went one way, while those of iron went the other way. This metal, it would seem, has an origin entirely different from that of the rest of the globe. It is highly improbable that we shall discover some other and cheaper material which will equal or surpass iron in magnetic qualities.

Unless we should make a radical departure in the character of the electric currents employed, iron will be indispensable. Yet

the advantages it offers are only apparent. So long as we use feeble magnetic forces it is by far superior to any other material; but if we find ways of producing great magnetic forces, then better results will be obtainable without it. In fact, I have already produced electric transformers in which no iron is employed, and which are capable of performing ten times as much work per pound of weight as those with iron. This result is attained by using electric currents of a very high rate of vibration, produced in novel ways, instead of the ordinary currents now employed in the industries. I have also succeeded in operating electric motors without iron by such rapidly vibrating currents, but the results, so far, have been inferior to those obtained with ordinary motors constructed of iron, although theoretically the former should be capable of performing incomparably more work per unit of weight than the latter. But the seemingly insuperable difficulties which are now in the way may be overcome in the end, and then iron will be done away with, and all electric machinery will be manufactured of aluminium, in all probability, at prices ridiculously low. This would be a severe, if not a fatal, blow to iron. In many other branches of industry, as ship-building, or wherever lightness of structure is required, the progress of the new metal will be much quicker. For such uses it is eminently suitable, and is sure to supersede iron sooner or later. It is highly probable that in the course of time we shall be able to give it many of those qualities which make iron so valuable.

While it is impossible to tell when this industrial revolution will be consummated, there can be no doubt that the future belongs to aluminium, and that in times to come it will be the chief means of increasing human performance. It has in this respect capacities greater by far than those of any other metal. I should estimate its civilizing potency at fully one hundred times that of iron. This estimate, though it may astonish, is not at all exaggerated. First of all, we must remember that there is thirty times as much aluminium as iron in bulk, available for the uses of man. This in itself offers great possibilities. Then, again, the new metal is much more easily workable, which adds to its value. In many of its properties it partakes of the character of a precious metal, which gives it additional worth. Its electric conductivity, which, for a given weight, is greater than that of any other metal, would be alone sufficient to make it one of the most important factors in future human progress. Its extreme lightness makes it far more easy to transport the objects manufactured. By virtue of this property it will revolutionize naval construction, and in facilitating transport and travel it will add enormously to the useful performance of mankind. But its greatest civilizing potency will be, I believe, in aërial travel, which is sure to be brought about by means of it. Telegraphic instruments will slowly enlighten the barbarian. Electric motors and lamps will do it more quickly, but quicker than anything else the flying-machine will do it. By rendering travel ideally easy it will be the best means for unifying the heterogeneous elements of humanity. As the first step toward this realization we should produce a lighter storage-battery or get more energy from coal.

EFFORTS TOWARD OBTAINING MORE ENERGY FROM COAL—THE ELECTRIC TRANSMISSION—THE GAS-ENGINE—THE COLD-COAL BATTERY.

I REMEMBER that at one time I considered the production of electricity by burning coal in a battery as the greatest achievement toward advancing civilization, and I am surprised to find how much the continuous study of these subjects has modified my views. It now seems to me that to burn coal, however efficiently, in a battery would be a mere makeshift, a phase in the evolution toward something much more perfect. After all, in generating electricity in this manner, we should be destroying material, and this would be a barbarous process. We ought to be able to obtain the energy we need without consumption of material. But I am far from underrating the value of such an efficient method of burning fuel. At the present time most motive power comes from coal, and, either directly or by its products, it adds vastly to human energy. Unfortunately, in all the processes now adopted, the larger portion of the energy of the coal is uselessly dissipated. The best steam-engines utilize only a small part of the total energy. Even in gas-engines, in which, particularly of late, better results are obtainable, there is still a barbarous waste going on. In our electric-lighting systems we scarcely utilize one third of one per cent., and in lighting by gas a much smaller fraction, of the total energy of the coal. Considering the various uses of coal throughout the world, we certainly do not utilize more than two per cent. of its energy theoretically available. The man who should stop this senseless waste would be a great

benefactor of humanity, though the solution he would offer could not be a permanent one, since it would ultimately lead to the exhaustion of the store of material. Efforts toward obtaining more energy from coal are now being made chiefly in two directions—by generating electricity and by producing gas for motive-power purposes. In both of these lines notable success has already been achieved.

The advent of the alternating-current system of electric power-transmission marks an epoch in the economy of energy available to man from coal. Evidently all electrical energy obtained from a waterfall, saving so much fuel, is a net gain to mankind, which is all the more effective as it is secured with little expenditure of human effort, and as this most perfect of all known methods of deriving energy from the sun contributes in many ways to the advancement of civilization. But electricity enables us also to get from coal much more energy than was practicable in the old ways. Instead of transporting the coal to distant places of consumption, we burn it near the mine, develop electricity in the dynamos, and transmit the current to remote localities, thus effecting a considerable saving. Instead of driving the machinery in a factory in the old wasteful way by belts and shafting, we generate electricity by steam-power and operate electric motors. In this manner it is not uncommon to obtain two or three times as much effective motive power from the fuel, besides securing many other important advantages. It is in this field as much as in the transmission of energy to great distances that the alternating system, with its ideally simple machinery, is bringing about an industrial revolution. But in many lines this progress has not yet been felt. For example, steamers and trains are still being propelled by the direct application of steam-power to shafts or axles. A much greater percentage of the heat-energy of the fuel could be transformed in motive energy by using, in place of the adopted marine engines and locomotives, dynamos driven by specially designed high-pressure steam- or gas-engines and by utilizing the electricity generated for the propulsion. A gain of fifty to one hundred per cent. in the effective energy derived from the coal could be secured in this manner. It is difficult to understand why a fact so plain and obvious is not receiving more attention from engineers. In ocean steamers such an improvement would be particularly desirable, as it would do away with noise and increase materially the speed and the carrying capacity of the liners.

Still more energy is now being obtained from coal by the latest improved gas-engine, the economy of which is, on the average, probably twice that of the best steam-engine. The introduction of the gas-engine is very much facilitated by the importance of the gas industry. With the increasing use of the electric light more and more of the gas is utilized for heating and motive-power purposes. In many instances gas is manufactured close to the coal-mine and conveyed to distant places of consumption, a considerable saving both in the cost of transportation and in utilization of the energy of the fuel being thus effected. In the present state of the mechanical and electrical arts the most rational way of deriving energy from coal is evidently to manufacture gas close to the coal store, and to utilize it, either on the spot or elsewhere, to generate electricity for industrial uses in dynamos driven by gas-engines. The commercial success of such a plant is largely dependent upon the production of gas-engines of great nominal horse-power, which, judging from the keen activity in this field, will soon be forthcoming. Instead of consuming coal directly, as usual, gas should be manufactured from it and burned to economize energy.

But all such improvements cannot be more than passing phases in the evolution toward something far more perfect, for ultimately we must succeed in obtaining electricity from coal in a more direct way, involving no great loss of its heat-energy. Whether coal can be oxidized by a cold process is still a question. Its combination with oxygen always evolves heat, and whether the energy of the combination of the carbon with another element can be turned directly into electrical energy has not yet been determined. Under certain conditions nitric acid will burn the carbon, generating an electric current, but the solution does not remain cold. Other means of oxidizing coal have been proposed, but they have offered no promise of leading to an efficient process. My own lack of success has been complete, though perhaps not quite so complete as that of some who have "perfected" the cold-coal battery. This problem is essentially one for the chemist to solve. It is not for the physicist, who determines all his results in advance, so that, when the experiment is tried, it cannot fail. Chemistry, though a positive science, does not yet admit of a solution by

such positive methods as those which are available in the treatment of many physical problems. The result, if possible, will be arrived at through patient trying rather than through deduction or calculation. The time will soon come, however, when the chemist will be able to follow a course clearly mapped out beforehand, and when the process of his arriving at a desired result will be purely constructive. The cold-coal battery would give a great impetus to electrical development; it would lead very shortly to a practical flying-machine, and would enormously enhance the introduction of the automobile. But these and many other problems will be better solved, and in a more scientific manner, by a light-storage battery.

ENERGY FROM THE MEDIUM—THE WINDMILL AND THE SOLAR ENGINE—MOTIVE POWER FROM TERRESTRIAL HEAT—ELECTRICITY FROM NATURAL SOURCES.

BESIDES fuel, there is abundant material from which we might eventually derive power. An immense amount of energy is locked up in limestone, for instance, and machines can be driven by liberating the carbonic acid through sulphuric acid or otherwise. I once constructed such an engine, and it operated satisfactorily.

But, whatever our resources of primary energy may be in the future, we must, to be rational, obtain it without consumption of any material. Long ago I came to this conclusion, and to arrive at this result only two ways, as before indicated, appeared possible—either to turn to use the energy of the sun stored in the ambient medium, or to transmit, through the medium, the sun's energy to distant places from some locality where it was obtainable without consumption of material. At that time I at once rejected the latter method as entirely impracticable, and turned to examine the possibilities of the former.

It is difficult to believe, but it is, nevertheless, a fact, that since time immemorial man has had at his disposal a fairly good machine which has enabled him to utilize the energy of the ambient medium. This machine is the windmill. Contrary to popular belief, the power obtainable from wind is very considerable. Many a deluded inventor has spent years of his life in endeavoring to "harness the tides," and some have even proposed to compress air by tide- or wave-power for supplying energy, never understanding the signs of the old windmill on the hill, as it sorrowfully waved its arms about and bade them stop. The fact is that a wave- or tide-motor would have, as a rule, but a small chance of competing commercially with the windmill, which is by far the better machine, allowing a much greater amount of energy to be obtained in a simpler way. Wind-power has been, in old times, of inestimable value to man, if for nothing else but for enabling him to cross the seas, and it is even now a very important factor in travel and transportation. But there are great limitations in this ideally simple method of utilizing the sun's energy. The machines are large for a given output, and the power is intermittent, thus necessitating the storage of energy and increasing the cost of the plant.

A far better way, however, to obtain power would be to avail ourselves of the sun's rays, which beat the earth incessantly and supply energy at a maximum rate of over four million horse-power per square mile. Although the average energy received per square mile in any locality during the year is only a small fraction of that amount, yet an inexhaustible source of power would be opened up by the discovery of some efficient method of utilizing the energy of the rays. The only rational way known to me at the time when I began the study of this subject was to employ some kind of heat- or thermodynamic engine, driven by a volatile fluid evaporated in a boiler by the heat of the rays. But closer investigation of this method, and calculation, showed that, notwithstanding the apparently vast amount of energy received from the sun's rays, only a small fraction of that energy could be actually utilized in this manner. Furthermore, the energy supplied through the sun's radiations is periodical, and the same limitations as in the use of the windmill I found to exist here also. After a long study of this mode of obtaining motive power from the sun, taking into account the necessarily large bulk of the boiler, the low efficiency of the heat-engine, the additional cost of storing the energy, and other drawbacks, I came to the conclusion that the "solar engine," a few instances excepted, could not be industrially exploited with success.

Another way of getting motive power from the medium without consuming any material would be to utilize the heat contained in the earth, the water, or the air for driving an engine. It is a well-known fact that the interior portions of the globe are very hot, the temperature rising, as observa-

tions show, with the approach to the center at the rate of approximately 1° C. for every hundred feet of depth. The difficulties of sinking shafts and placing boilers at depths of, say, twelve thousand feet, corresponding to an increase in temperature of about 120° C., are not insuperable, and we could certainly avail ourselves in this way of the internal heat of the globe. In fact, it would not be necessary to go to any depth at all in order to derive energy from the stored terrestrial heat. The superficial layers of the earth and the air strata close to the same are at a temperature sufficiently high to evaporate some extremely volatile substances, which we might use in our boilers instead of water. There is no doubt that a vessel might be propelled on the ocean by an engine driven by such a volatile fluid, no other energy being used but the heat abstracted from the water. But the amount of power which could be obtained in this manner would be, without further provision, very small.

Electricity produced by natural causes is another source of energy which might be rendered available. Lightning discharges involve great amounts of electrical energy, which we could utilize by transforming and storing it. Some years ago I made known a method of electrical transformation which renders the first part of this task easy, but the storing of the energy of lightning discharges will be difficult to accomplish. It is well known, furthermore, that electric currents circulate constantly through the earth, and that there exists between the earth and any air stratum a difference of electrical pressure, which varies in proportion to the height.

In recent experiments I have discovered two novel facts of importance in this connection. One of these facts is that an electric current is generated in a wire extending from the ground to a great height by the axial, and probably also by the translatory, movement of the earth. No appreciable current, however, will flow continuously in the wire unless the electricity is allowed to leak out into the air. Its escape is greatly facilitated by providing at the elevated end of the wire a conducting terminal of great surface, with many sharp edges or points. We are thus enabled to get a continuous supply of electrical energy by merely supporting a wire at a height, but, unfortunately, the amount of electricity which can be so obtained is small.

The second fact which I have ascertained is that the upper air strata are permanently charged with electricity opposite to that of the earth. So, at least, I have interpreted my observations, from which it appears that the earth, with its adjacent insulating and outer conducting envelop, constitutes a highly charged electrical condenser containing, in all probability, a great amount of electrical energy which might be turned to the uses of man, if it were possible to reach with a wire to great altitudes.

It is possible, and even probable, that there will be, in time, other resources of energy opened up, of which we have no knowledge now. We may even find ways of applying forces such as magnetism or gravity for driving machinery without using any other means. Such realizations, though highly improbable, are not impossible. An example will best convey an idea of what we can hope to attain and what we can never attain. Imagine a disk of some homogeneous material turned perfectly true and arranged to turn in frictionless bearings on a horizontal shaft above the ground. This disk, being under the above conditions perfectly balanced, would rest in any position. Now, it is possible that we may learn how to make such a disk rotate continuously and perform work by the force of gravity without any further effort on our part; but it is perfectly impossible for the disk to turn and to do work without any force from the outside. If it could do so, it would be what is designated scientifically as a "perpetuum mobile," a machine creating its own motive power. To make the disk rotate by the force of gravity we have only to invent a screen against this force. By such a screen we could prevent this force from acting on one half of the disk, and the rotation of the latter would follow. At least, we cannot deny such a possibility until we know exactly the nature of the force of gravity. Suppose that this force were due to a movement comparable to that of a stream of air passing from above toward the center of the earth. The effect of such a stream upon both halves of the disk would be equal, and the latter would not rotate ordinarily; but if one half should be guarded by a plate arresting the movement, then it would turn.

A DEPARTURE FROM KNOWN METHODS—POSSIBILITY OF A "SELF-ACTING" ENGINE OR MACHINE, INANIMATE, YET CAPABLE, LIKE A LIVING BEING, OF DERIVING ENERGY FROM THE MEDIUM—THE IDEAL WAY OF OBTAINING MOTIVE POWER.

WHEN I began the investigation of the subject under consideration, and when the preceding or similar ideas presented themselves

to me for the first time, though I was then unacquainted with a number of the facts mentioned, a survey of the various ways of utilizing the energy of the medium convinced me, nevertheless, that to arrive at a thoroughly satisfactory practical solution a radical departure from the methods then known had to be made. The windmill, the solar engine, the engine driven by terrestrial heat, had their limitations in the amount of power obtainable. Some new way had to be discovered which would enable us to get more energy. There was enough heat-energy in the medium, but only a small part of it was available for the operation of an engine in the ways then known. Besides, the energy was obtainable only at a very slow rate. Clearly, then, the problem was to discover some new method which would make it possible both to utilize more of the heat-energy of the medium and also to draw it away from the same at a more rapid rate.

I was vainly endeavoring to form an idea of how this might be accomplished, when I read some statements from Carnot and Lord Kelvin (then Sir William Thomson) which meant virtually that it is impossible for an inanimate mechanism or self-acting machine to cool a portion of the medium below the temperature of the surrounding, and operate by the heat abstracted. These statements interested me intensely. Evidently a living being could do this very thing, and since the experiences of my early life which I have related had convinced me that a living being is only an automaton, or, otherwise stated, a "self-acting engine," I came to the conclusion that it was possible to construct a machine which would do the same. As the first step toward this realization I conceived the following mechanism. Imagine a thermopile consisting of a number of bars of metal extending from the earth to the outer space beyond the atmosphere. The heat from below, conducted upward along these metal bars, would cool the earth or the sea or the air, according to the location of the lower parts of the bars, and the result, as is well known, would be an electric current circulating in these bars. The two terminals of the thermopile could now be joined through an electric motor, and, theoretically, this motor would run on and on, until the media below would be cooled down to the temperature of the outer space. This would be an inanimate engine which, to all evidence, would be cooling a portion of the medium below the temperature of the surrounding, and operating by the heat abstracted.

But was it not possible to realize a similar condition without necessarily going to a height? Conceive, for the sake of illustration, an inclosure T, as illustrated in diagram b, such that energy could not be transferred across it except through a channel or path O, and that, by some means or other, in this inclosure a medium were maintained which would have little energy, and that on the outer side of the same there would be the ordinary ambient medium with much energy. Under these assumptions the energy would flow through the path O, as indicated by the arrow, and might then be converted on its passage into some other form of energy. The question was, Could such a condition be attained? Could we produce artificially such a "sink" for the energy of the ambient medium to flow in? Suppose that an extremely low temperature could be maintained by some process in a given space; the surrounding medium would then be compelled to give off heat, which could be converted into mechanical or other form of energy, and utilized. By realizing such a plan, we should be enabled to get at any point of the globe a continuous supply of energy, day and night. More than this, reasoning in the abstract, it would seem possible to cause a quick circulation of the medium, and thus draw the energy at a very rapid rate.

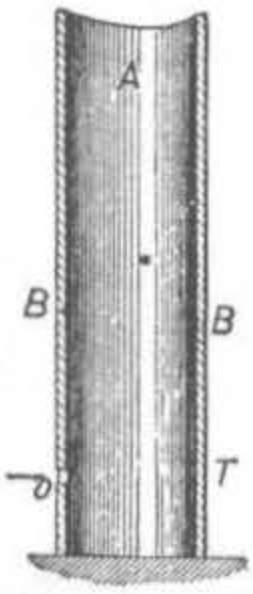

DIAGRAM *b*. OBTAINING ENERGY FROM THE AMBIENT MEDIUM.

A, medium with little energy; *B*, *B*, ambient medium with much energy; *O*, path of the energy.

Here, then, was an idea which, if realizable, afforded a happy solution of the problem of getting energy from the medium. But was it realizable? I convinced myself that it was so in a number of ways, of which one is the following. As regards heat, we are at a high level, which may be represented by the surface of a mountain lake considerably above the sea, the level of which may mark the absolute zero of temperature existing in the interstellar space. Heat, like water, flows

from high to low level, and, consequently, just as we can let the water of the lake run down to the sea, so we are able to let heat from the earth's surface travel up into the cold region above. Heat, like water, can perform work in flowing down, and if we had any doubt as to whether we could derive energy from the medium by means of a thermopile, as before described, it would be dispelled by this analogue. But can we produce cold in a given portion of the space and cause the heat to flow in continually? To create such a "sink," or "cold hole," as we might say, in the medium, would be equivalent to producing in the lake a space either empty or filled with something much lighter than water. This we could do by placing in the lake a tank, and pumping all the water out of the latter. We know, then, that the water, if allowed to flow back into the tank, would, theoretically, be able to perform exactly the same amount of work which was used in pumping it out, but not a bit more. Consequently nothing could be gained in this double operation of first raising the water and then letting it fall down. This would mean that it is impossible to create such a sink in the medium. But let us reflect a moment. Heat, though following certain general laws of mechanics, like a fluid, is not such; it is energy which may be converted into other forms of energy as it passes from a high to a low level. To make our mechanical analogy complete and true, we must, therefore, assume that the water, in its passage into the tank, is converted into something else, which may be taken out of it without using any, or by using very little, power. For example, if heat be represented in this analogue by the water of the lake, the oxygen and hydrogen composing the water may illustrate other forms of energy into which the heat is transformed in passing from hot to cold. If the process of heat-transformation were absolutely perfect, no heat at all would arrive at the low level, since all of it would be converted into other forms of energy. Corresponding to this ideal case, all the water flowing into the tank would be decomposed into oxygen and hydrogen before reaching the bottom, and the result would be that water would continually flow in, and yet the tank would remain entirely empty, the gases formed escaping. We would thus produce, by expending initially a certain amount of work to create a sink for the heat or, respectively, the water to flow in, a condition enabling us to get any amount of energy without further effort. This would be an ideal way of obtaining motive power. We do not know of any such absolutely perfect process of heat-conversion, and consequently some heat will generally reach the low level, which means to say, in our mechanical analogue, that some water will arrive at the bottom of the tank, and a gradual and slow filling of the latter will take place, necessitating continuous pumping out. But evidently there will be less to pump out than flows in, or, in other words, less energy will be needed to maintain the initial condition than is developed by the fall, and this is to say that some energy will be gained from the medium. What is not converted in flowing down can just be raised up with its own energy, and what is converted is clear gain. Thus the virtue of the principle I have discovered resides wholly in the conversion of the energy on the downward flow.

FIRST EFFORTS TO PRODUCE THE SELF-ACTING ENGINE—THE MECHANICAL OSCILLATOR—WORK OF DEWAR AND LINDE—LIQUID AIR.

HAVING recognized this truth, I began to devise means for carrying out my idea, and, after long thought, I finally conceived a combination of apparatus which should make possible the obtaining of power from the medium by a process of continuous cooling of atmospheric air. This apparatus, by continually transforming heat into mechanical work, tended to become colder and colder, and if it only were practicable to reach a very low temperature in this manner, then a sink for the heat could be produced, and energy could be derived from the medium. This seemed to be contrary to the statements of Carnot and Lord Kelvin before referred to, but I concluded from the theory of the process that such a result could be attained. This conclusion I reached, I think, in the latter part of 1883, when I was in Paris, and it was at a time when my mind was being more and more dominated by an invention which I had evolved during the preceding year, and which has since become known under the name of the "rotating magnetic field." During the few years which followed I elaborated further the plan I had imagined, and studied the working conditions, but made little headway. The commercial introduction in this country of the invention before referred to required most of my energies until 1889, when I again took up the idea of the self-acting machine. A closer in-

vestigation of the principles involved, and calculation, now showed that the result I aimed at could not be reached in a practical manner by ordinary machinery, as I had in the beginning expected. This led me, as a next step, to the study of a type of engine generally designated as "turbine," which at first seemed to offer better chances for a realization of the idea. Soon I found, however, that the turbine, too, was unsuitable. But my conclusions showed that if an engine of a peculiar kind could be brought to a high degree of perfection, the plan I had conceived was realizable, and I resolved to proceed with the development of such an engine, the primary object of which was to secure the greatest economy of transformation of heat into mechanical energy. A characteristic feature of the engine was that the work-performing piston was not connected with anything else, but was perfectly free to vibrate at an enormous rate. The mechanical difficulties encountered in the construction of this engine were greater than I had anticipated, and I made slow progress. This work was continued until early in 1892, when I went to London, where I saw Professor Dewar's admirable experiments with liquefied gases. Others had liquefied gases before, and notably Ozlewski and Pictet had performed creditable early experiments in this line, but there was such a vigor about the work of Dewar that even the old appeared new. His experiments showed, though in a way different from that I had imagined, that it was possible to reach a very low temperature by transforming heat into mechanical work, and I returned, deeply impressed with what I had seen, and more than ever convinced that my plan was practicable. The work temporarily interrupted was taken up anew, and soon I had in a fair state of perfection the engine which I have named "the mechanical oscillator." In this machine I succeeded in doing away with all packings, valves, and lubrication, and in producing so rapid a vibration of the piston that shafts of tough steel, fastened to the same and vibrated longitudinally, were torn asunder. By combining this engine with a dynamo of special design I produced a highly efficient electrical generator, invaluable in measurements and determinations of physical quantities on account of the unvarying rate of oscillation obtainable by its means. I exhibited several types of this machine, named "mechanical and electrical oscillator," before the Electrical Congress at the World's Fair in Chicago during the summer of 1893, in a lecture which, on account of other pressing work, I was unable to prepare for publication. On that occasion I exposed the principles of the mechanical oscillator, but the original purpose of this machine is explained here for the first time.

In the process, as I had primarily conceived it, for the utilization of the energy of the ambient medium, there were five essential elements in combination, and each of these had to be newly designed and perfected, as no such machines existed. The mechanical oscillator was the first element of this combination, and having perfected this, I turned to the next, which was an air-compressor of a design in certain respects resembling that of the mechanical oscillator. Similar difficulties in the construction were again encountered, but the work was pushed vigorously, and at the close of 1894 I had completed these two elements of the combination, and thus produced an apparatus for compressing air, virtually to any desired pressure, incomparably simpler, smaller, and more efficient than the ordinary. I was just beginning work on the third element, which together with the first two would give a refrigerating machine of exceptional efficiency and simplicity, when a misfortune befell me in the burning of my laboratory, which crippled my labors and delayed me. Shortly afterward Dr. Carl Linde announced the liquefaction of air by a self-cooling process, demonstrating that it was practicable to proceed with the cooling until liquefaction of the air took place. This was the only experimental proof which I was still wanting that energy was obtainable from the medium in the manner contemplated by me.

The liquefaction of air by a self-cooling process was not, as popularly believed, an accidental discovery, but a scientific result which could not have been delayed much longer, and which, in all probability, could not have escaped Dewar. This fascinating advance, I believe, is largely due to the powerful work of this great Scotchman. Nevertheless, Linde's is an immortal achievement. The manufacture of liquid air has been carried on for four years in Germany, on a scale much larger than in any other country, and this strange product has been applied for a variety of purposes. Much was expected of it in the beginning, but so far it has been an industrial ignis fatuus. By the use of such machinery as I am perfecting, its cost will probably be greatly lessened, but even then its commercial success will be ques-

tionable. When used as a refrigerant it is uneconomical, as its temperature is unnecessarily low. It is as expensive to maintain a body at a very low temperature as it is to keep it very hot; it takes coal to keep air cold. In oxygen manufacture it cannot yet compete with the electrolytic method. For use as an explosive it is unsuitable, because its low temperature again condemns it to a small efficiency, and for motive-power purposes its cost is still by far too high. It is of interest to note, however, that in driving an engine by liquid air a certain amount of energy may be gained from the engine, or, stated otherwise, from the ambient medium which keeps the engine warm, each two hundred pounds of iron-casting of the latter contributing energy at the rate of about one effective horse-power during one hour. But this gain of the consumer is offset by an equal loss of the producer.

Much of this task on which I have labored so long remains to be done. A number of mechanical details are still to be perfected and some difficulties of a different nature to be mastered, and I cannot hope to produce a self-acting machine deriving energy from the ambient medium for a long time yet, even if all my expectations should materialize. Many circumstances have occurred which have retarded my work of late, but for several reasons the delay was beneficial.

One of these reasons was that I had ample time to consider what the ultimate possibilities of this development might be. I worked for a long time fully convinced that the practical realization of this method of obtaining energy from the sun would be of incalculable industrial value, but the continued study of the subject revealed the fact that while it will be commercially profitable if my expectations are well founded, it will not be so to an extraordinary degree.

DISCOVERY OF UNEXPECTED PROPERTIES OF THE ATMOSPHERE—STRANGE EXPERIMENTS—TRANSMISSION OF ELECTRICAL ENERGY THROUGH ONE WIRE WITHOUT RETURN—TRANSMISSION THROUGH THE EARTH WITHOUT ANY WIRE.

ANOTHER of these reasons was that I was led to recognize the transmission of electrical energy to any distance through the media as by far the best solution of the great problem of harnessing the sun's energy for the uses of man. For a long time I was convinced that such a transmission on an industrial scale could never be realized, but a discovery which I made changed my view. I observed that under certain conditions the atmosphere, which is normally a high insulator, assumes conducting properties, and so becomes capable of conveying any amount of electrical energy. But the difficulties in the way of a practical utilization of this discovery for the purpose of transmitting electrical energy without wires were seemingly insuperable. Electrical pressures of many millions of volts had to be produced and handled; generating apparatus of a novel kind, capable of withstanding the immense electrical stresses, had to be invented and perfected, and a complete safety against the dangers of the high-tension currents had to be attained in the system before its practical introduction could be even thought of. All this could not be done in a few weeks or months, or even years. The work required patience and constant application, but the improvements came, though slowly. Other valuable results were, however, arrived at in the course of this long-continued work, of which I shall endeavor to give a brief account, enumerating the chief advances as they were successively effected.

The discovery of the conducting properties of the air, though unexpected, was only a natural result of experiments in a special field which I had carried on for some years before. It was, I believe, during 1889 that certain possibilities offered by extremely rapid electrical oscillations determined me to design a number of special machines adapted for their investigation. Owing to the peculiar requirements, the construction of these machines was very difficult, and consumed much time and effort; but my work on them was generously rewarded, for I reached by their means several novel and important results. One of the earliest observations I made with these new machines was that electrical oscillations of an extremely high rate act in an extraordinary manner upon the human organism. Thus, for instance, I demonstrated that powerful electrical discharges of several hundred thousand volts, which at that time were considered absolutely deadly, could be passed through the body without inconvenience or hurtful consequences. These oscillations produced other specific physiological effects, which, upon my announcement, were eagerly taken up by skilled physicians and further investigated. This new field has proved itself fruitful beyond expectation, and in the few years which have passed since, it has been

developed to such an extent that it now forms a legitimate and important department of medical science. Many results, thought impossible at that time, are now readily obtainable with these oscillations, and many experiments undreamed of then can now be readily performed by their means. I still remember with pleasure how, nine years ago, I passed the discharge of a powerful induction-coil through my body to demonstrate before a scientific society the comparative harmlessness of very rapidly vibrating electric currents, and I can still recall the astonishment of my audience. I would now undertake, with much less apprehension than I had in that experiment, to transmit through my body with such currents the entire electrical energy of the dynamos now working at Niagara—forty or fifty thousand horsepower. I have produced electrical oscillations which were of such intensity that when circulating through my arms and chest they have melted wires which joined my hands, and still I felt no inconvenience. I have energized with such oscillations a loop of heavy copper wire so powerfully that masses of metal, and even objects of an electrical resistance specifically greater than that of human tissue, brought close to or placed within the loop, were heated to a high temperature and melted, often with the violence of an explosion, and yet into this very space in which this terribly destructive turmoil was going on I have repeatedly thrust my head without feeling anything or experiencing injurious after-effects.

Another observation was that by means of such oscillations light could be produced in a novel and more economical manner, which promised to lead to an ideal system of electric illumination by vacuum-tubes, dispensing with the necessity of renewal of lamps or incandescent filaments, and possibly also with the use of wires in the interior of buildings. The efficiency of this light increases in proportion to the rate of the oscillations, and its commercial success is, therefore, dependent on the economical production of electrical vibrations of transcending rates. In this direction I have met with gratifying success of late, and the practical introduction of this new system of illumination is not far off.

The investigations led to many other valuable observations and results, one of the more important of which was the demonstration of the practicability of supplying electrical energy through one wire without return. At first I was able to transmit in this novel manner only very small amounts of electrical energy, but in this line also my efforts have been rewarded with similar success.

The photograph shown in Fig. 3 (see p. 186) illustrates, as its title explains, an actual transmission of this kind effected with apparatus used in other experiments here described. To what a degree the appliances have been perfected since my first demonstrations early in 1891 before a scientific society, when my apparatus was barely capable of lighting one lamp (which result was considered wonderful), will appear when I state that I have now no difficulty in lighting in this manner four or five hundred lamps, and could light many more. In fact, there is no limit to the amount of energy which may in this way be supplied to operate any kind of electrical device.

After demonstrating the practicability of this method of transmission, the thought naturally occurred to me to use the earth as a conductor, thus dispensing with all wires. Whatever electricity may be, it is a fact that it behaves like an incompressible fluid, and the earth may be looked upon as an immense reservoir of electricity, which, I thought, could be disturbed effectively by a properly designed electrical machine. Accordingly, my next efforts were directed toward perfecting a special apparatus which would be highly effective in creating a disturbance of electricity in the earth. The progress in this new direction was necessarily very slow and the work discouraging, until I finally succeeded in perfecting a novel kind of transformer or induction-coil, particularly suited for this special purpose. That it is practicable, in this manner, not only to transmit minute amounts of electrical energy for operating delicate electrical devices, as I contemplated at first, but also electrical energy in appreciable quantities, will appear from an inspection of Fig. 4 (see p. 186), which illustrates an actual experiment of this kind performed with the same apparatus. The result obtained was all the more remarkable as the top end of the coil was not connected to a wire or plate for magnifying the effect.

"WIRELESS" TELEGRAPHY—THE SECRET OF TUNING—ERRORS IN THE HERTZIAN INVESTIGATIONS—A RECEIVER OF WONDERFUL SENSITIVENESS.

As the first valuable result of my experiments in this latter line a system of telegraphy without wires resulted, which I described in two

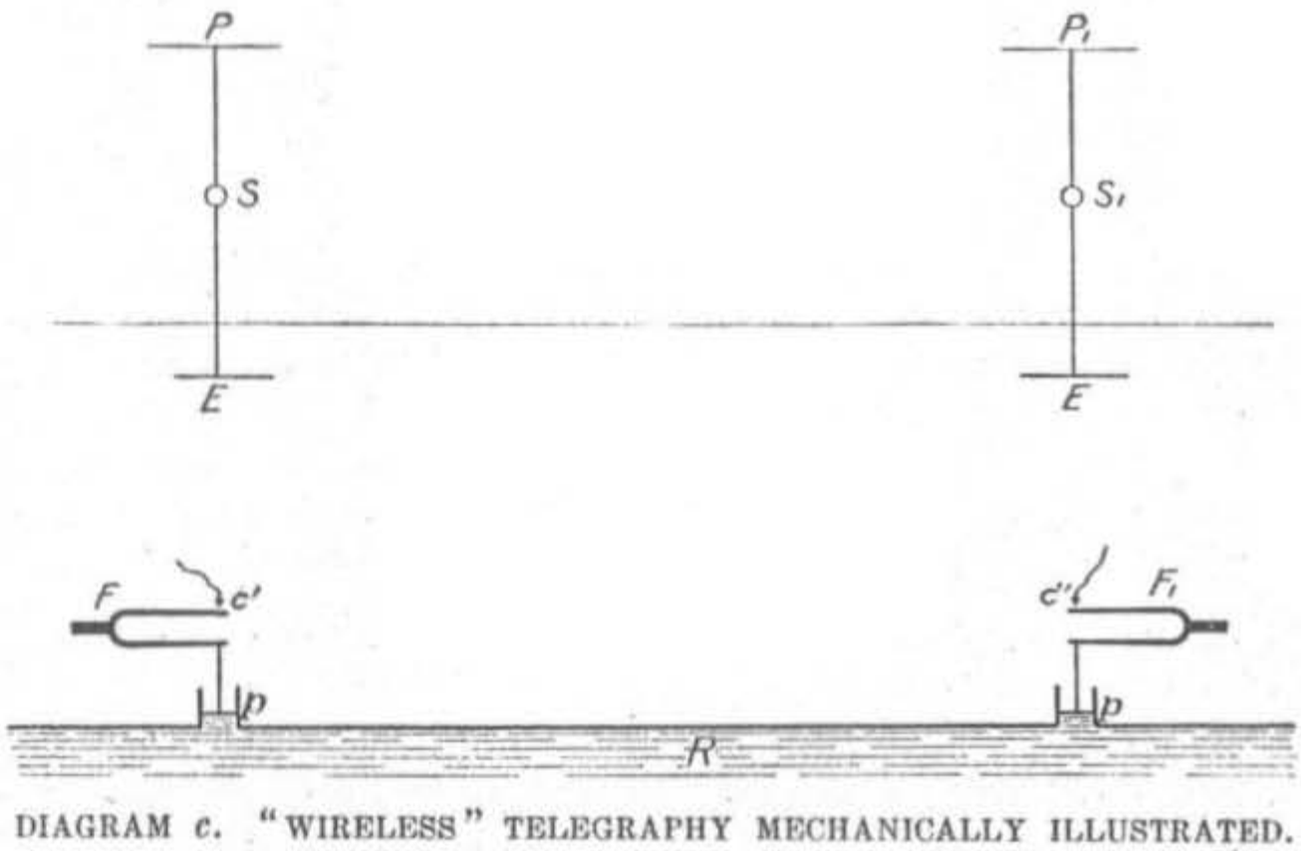

DIAGRAM *c*. "WIRELESS" TELEGRAPHY MECHANICALLY ILLUSTRATED.

scientific lectures in February and March, 1893. It is mechanically illustrated in diagram *c*, the upper part of which shows the electrical arrangement as I described it then, while the lower part illustrates its mechanical analogue. The system is extremely simple in principle. Imagine two tuning-forks *F*, F_1, one at the sending- and the other at the receiving-station respectively, each having attached to its lower prong a minute piston *p*, fitting in a cylinder. Both the cylinders communicate with a large reservoir *R*, with elastic walls, which is supposed to be closed and filled with a light and incompressible fluid. By striking repeatedly one of the prongs of the tuning-fork *F*, the small piston *p* below would be vibrated, and its vibrations, transmitted through the fluid, would reach the distant fork F_1, which is "tuned" to the fork *F*, or, stated otherwise, of exactly the same note as the latter. The fork F_1 would now be set vibrating, and its vibration would be intensified by the continued action of the distant fork *F* until its upper prong, swinging far out, would make an electrical connection with a stationary contact *c''*, starting in this manner some electrical or other appliances which may be used for recording the signals. In this simple way messages could be exchanged between the two stations, a similar contact *c'* being provided for this purpose, close to the upper prong of the fork *F*, so that the apparatus at each station could be employed in turn as receiver and transmitter.

The electrical system illustrated in the upper figure of diagram *c* is exactly the same in principle, the two wires or circuits *ESP* and $E_1S_1P_1$, which extend vertically to a height, representing the two tuning-forks with the pistons attached to them. These circuits are connected with the ground by plates *E*, E_1, and to two elevated metal sheets *P*, P_1, which store electricity and thus magnify considerably the effect. The closed reservoir *R*, with elastic walls, is in this case replaced by the earth, and the fluid by electricity. Both of these circuits are "tuned" and operate just like the two tuning-forks. Instead of striking the fork *F* at the sending-station, electrical oscillations are produced in the vertical sending- or transmitting-wire *ESP*, as by the action of a source *S*, included in this wire, which spread through the ground and reach the distant vertical receiving-wire $E_1S_1P_1$, exciting corresponding electrical oscillations in the same. In the latter wire or circuit is included a sensitive device or receiver S_1, which is thus set in action and made to operate a relay or other appliance. Each station is, of course, provided both with a source of electrical oscillations *S* and a sensitive receiver S_1, and a simple provision is made for using each of the two wires alternately to send and to receive the messages.

The exact attunement of the two circuits secures great advantages, and, in fact, it is essential in the practical use of the system. In this respect many popular errors exist, and, as a rule, in the technical reports on this subject circuits and appliances are described as affording these advantages when from their very nature it is evident that this is impossible. In order to attain the best results it is essential that the length of each wire or circuit, from the ground connection to the top, should be equal to one quarter of the wave-length of the electrical vibration in the wire, or else equal to that length multiplied by an odd number. Without the observation of this rule it is virtually impossible to prevent the interference and insure the privacy of messages. Therein lies the secret of tuning. To obtain the most satisfactory results it is, however, necessary to resort to electrical vibrations of low pitch. The Hertzian spark apparatus, used generally by experimenters, which produces oscillations of a very high rate, permits no effective tuning, and slight disturbances are sufficient to render an exchange of messages impracticable. But scientifically designed, efficient appliances allow nearly perfect adjustment. An experiment performed with the improved apparatus repeatedly referred to, and intended to convey an idea of this feature, is

illustrated in Fig. 5 (p. 187), which is sufficiently explained by its note.

Since I described these simple principles of telegraphy without wires I have had frequent occasion to note that the identical features and elements have been used, in the evident belief that the signals are being transmitted to considerable distances by "Hertzian" radiations. This is only one of many misapprehensions to which the investigations of the lamented physicist have given rise. About thirty-three years ago Maxwell, following up a suggestive experiment made by Faraday in 1845, evolved an ideally simple theory which intimately connected light, radiant heat, and electrical phenomena, interpreting them as being all due to vibrations of a hypothetical fluid of inconceivable tenuity, called the ether. No experimental verification was arrived at until Hertz, at the suggestion of Helmholtz, undertook a series of experiments to this effect. Hertz proceeded with extraordinary ingenuity and insight, but devoted little energy to the perfection of his old-fashioned apparatus. The consequence was that he failed to observe the important function which the air played in his experiments, and which I subsequently discovered. Repeating his experiments and reaching different results, I ventured to point out this oversight. The strength of the proofs brought forward by Hertz in support of Maxwell's theory resided in the correct estimate of the rates of vibration of the circuits he used. But I ascertained that he could not have obtained the rates he thought he was getting. The vibrations with identical apparatus he employed are, as a rule, much slower, this being due to the presence of air, which produces a dampening effect upon a rapidly vibrating electric circuit of high pressure, as a fluid does upon a vibrating tuning-fork. I have, however, discovered since that time other causes of error, and I have long ago ceased to look upon his results as being an experimental verification of the poetical conceptions of Maxwell. The work of the great German physicist has acted as an immense stimulus to contemporary electrical research, but it has likewise, in a measure, by its fascination, paralyzed the scientific mind, and thus hampered independent inquiry. Every new phenomenon which was discovered was made to fit the theory, and so very often the truth has been unconsciously distorted.

When I advanced this system of telegraphy, my mind was dominated by the idea of effecting communication to any distance through the earth or environing medium, the practical consummation of which I considered of transcendent importance, chiefly on account of the moral effect which it could not fail to produce universally. As the first effort to this end I proposed, at that time, to employ relay-stations with tuned circuits, in the hope of making thus practicable signaling over vast distances, even with apparatus of very moderate power then at my command. I was confident, however, that with properly designed machinery signals could be transmitted to any point of the globe, no matter what the distance, without the necessity of using such intermediate stations. I gained this conviction through the discovery of a singular electrical phenomenon, which I described early in 1892, in lectures delivered before some scientific societies abroad, and which I have called a "rotating brush." This is a bundle of light which is formed, under certain conditions, in a vacuum-bulb, and which is of a sensitiveness to magnetic and electric influences bordering, so to speak, on the supernatural. This light-bundle is rapidly rotated by the earth's magnetism as many as twenty thousand times per second, the rotation in these parts being opposite to what it would be in the southern hemisphere, while in the region of the magnetic equator it should not rotate at all. In its most sensitive state, which is difficult to attain, it is responsive to electric or magnetic influences to an incredible degree. The mere stiffening of the muscles of the arm and consequent slight electrical change in the body of an observer standing at some distance from it, will perceptibly affect it. When in this highly sensitive state it is capable of indicating the slightest magnetic and electric changes taking place in the earth. The observation of this wonderful phenomenon impressed me strongly that communication at any distance could be easily effected by its means, provided that apparatus could be perfected capable of producing an electric or magnetic change of state, however small, in the terrestrial globe or environing medium.

DEVELOPMENT OF A NEW PRINCIPLE—THE ELECTRICAL OSCILLATOR—PRODUCTION OF IMMENSE ELECTRICAL MOVEMENTS—THE EARTH RESPONDS TO MAN—INTERPLANETARY COMMUNICATION NOW PROBABLE.

I RESOLVED to concentrate my efforts upon this venturesome task, though it involved

great sacrifice, for the difficulties to be mastered were such that I could hope to consummate it only after years of labor. It meant delay of other work to which I would have preferred to devote myself, but I gained the conviction that my energies could not be more usefully employed; for I recognized that an efficient apparatus for the production of powerful electrical oscillations, as was needed for that specific purpose, was the key to the solution of other most important electrical and, in fact, human problems. Not only was communication, to any distance, without wires possible by its means, but, likewise, the transmission of energy in great amounts, the burning of the atmospheric nitrogen, the production of an efficient illuminant, and many other results of inestimable scientific and industrial value. Finally, however, I had the satisfaction of accomplishing the task undertaken by the use of a new principle, the virtue of which is based on the marvelous properties of the electrical condenser. One of these is that it can discharge or explode its stored energy in an inconceivably short time. Owing to this it is unequaled in explosive violence. The explosion of dynamite is only the breath of a consumptive compared with its discharge. It is the means of producing the strongest current, the highest electrical pressure, the greatest commotion in the medium. Another of its properties, equally valuable, is that its discharge may vibrate at any rate desired up to many millions per second.

I had arrived at the limit of rates obtainable in other ways when the happy idea presented itself to me to resort to the condenser. I arranged such an instrument so as to be charged and discharged alternately in rapid succession through a coil with a few turns of stout wire, forming the primary of a transformer or induction-coil. Each time the condenser was discharged the current would quiver in the primary wire and induce corresponding oscillations in the secondary. Thus a transformer or induction-coil on new principles was evolved, which I have called "the electrical oscillator," partaking of those unique qualities which characterize the condenser, and enabling results to be attained impossible by other means. Electrical effects of any desired character and of intensities undreamed of before are now easily producible by perfected apparatus of this kind, to which frequent reference has been made, and the essential parts of which are shown in Fig. 6 (p. 188). For certain purposes a strong inductive effect is required; for others the greatest possible suddenness; for others again, an exceptionally high rate of vibration or extreme pressure; while for certain other objects immense electrical movements are necessary. The photographs in Figs. 7, 8, 9, and 10, of experiments performed with such an oscillator, may serve to illustrate some of these features and convey an idea of the magnitude of the effects actually produced. The completeness of the titles of the figures referred to makes a further description of them unnecessary.

However extraordinary the results shown may appear, they are but trifling compared with those which are attainable by apparatus designed on these same principles. I have produced electrical discharges the actual path of which, from end to end, was probably more than one hundred feet long; but it would not be difficult to reach lengths one hundred times as great. I have produced electrical movements occurring at the rate of approximately one hundred thousand horse-power, but rates of one, five, or ten million horse-power are easily practicable. In these experiments effects were developed incomparably greater than any ever produced by human agencies, and yet these results are but an embryo of what is to be.

That communication without wires to any point of the globe is practicable with such apparatus would need no demonstration, but through a discovery which I made I obtained absolute certitude. Popularly explained, it is exactly this: When we raise the voice and hear an echo in reply, we know that the sound of the voice must have reached a distant wall, or boundary, and must have been reflected from the same. Exactly as the sound, so an electrical wave is reflected, and the same evidence which is afforded by an echo is offered by an electrical phenomenon known as a "stationary" wave—that is, a wave with fixed nodal and ventral regions. Instead of sending sound-vibrations toward a distant wall, I have sent electrical vibrations toward the remote boundaries of the earth, and instead of the wall the earth has replied. In place of an echo I have obtained a stationary electrical wave, a wave reflected from afar.

Stationary waves in the earth mean something more than mere telegraphy without wires to any distance. They will enable us to attain many important specific results impossible otherwise. For instance, by their use we may produce at will, from a sending-station, an electrical effect in any particular

region of the globe; we may determine the relative position or course of a moving object, such as a vessel at sea, the distance traversed by the same, or its speed; or we may send over the earth a wave of electricity traveling at any rate we desire, from the pace of a turtle up to lightning speed.

With these developments we have every reason to anticipate that in a time not very distant most telegraphic messages across the oceans will be transmitted without cables. For short distances we need a "wireless" telephone, which requires no expert operators. The greater the spaces to be bridged, the more rational becomes communication without wires. The cable is not only an easily damaged and costly instrument, but it limits us in the speed of transmission by reason of a certain electrical property inseparable from its construction. A properly designed plant for effecting communication without wires ought to have many times the working capacity of a cable, while it will involve incomparably less expense. Not a long time will pass, I believe, before communication by cable will become obsolete, for not only will signaling by this new method be quicker and cheaper, but also much safer. By using some new means for isolating the messages which I have contrived, an almost perfect privacy can be secured.

I have observed the above effects so far only up to a limited distance of about six hundred miles, but inasmuch as there is virtually no limit to the power of the vibrations producible with such an oscillator, I feel quite confident of the success of such a plant for effecting transoceanic communication. Nor is this all. My measurements and calculations have shown that it is perfectly practicable to produce on our globe, by the use of these principles, an electrical movement of such magnitude that, without the slightest doubt, its effect will be perceptible on some of our nearer planets, as Venus and Mars. Thus from mere possibility interplanetary communication has entered the stage of probability. In fact, that we can produce a distinct effect on one of these planets in this novel manner, namely, by disturbing the electrical condition of the earth, is beyond any doubt. This way of effecting such communication is, however, essentially different from all others which have so far been proposed by scientific men. In all the previous instances only a minute fraction of the total energy reaching the planet—as much as it would be possible to concentrate in a reflector—could be utilized by the supposed observer in his instrument. But by the means I have developed he would be enabled to concentrate the larger portion of the entire energy transmitted to the planet in his instrument, and the chances of affecting the latter are thereby increased many millionfold.

Besides machinery for producing vibrations of the required power, we must have delicate means capable of revealing the effects of feeble influences exerted upon the earth. For such purposes, too, I have perfected new methods. By their use we shall likewise be able, among other things, to detect at considerable distance the presence of an iceberg or other object at sea. By their use, also, I have discovered some terrestrial phenomena still unexplained. That we can send a message to a planet is certain, that we can get an answer is probable: man is not the only being in the Infinite gifted with a mind.

TRANSMISSION OF ELECTRICAL ENERGY TO ANY DISTANCE WITHOUT WIRES—NOW PRACTICABLE—THE BEST MEANS OF INCREASING THE FORCE ACCELERATING THE HUMAN MASS.

THE most valuable observation made in the course of these investigations was the extraordinary behavior of the atmosphere toward electric impulses of excessive electromotive force. The experiments showed that the air at the ordinary pressure became distinctly conducting, and this opened up the wonderful prospect of transmitting large amounts of electrical energy for industrial purposes to great distances without wires, a possibility which, up to that time, was thought of only as a scientific dream. Further investigation revealed the important fact that the conductivity imparted to the air by these electrical impulses of many millions of volts increased very rapidly with the degree of rarefaction, so that air strata at very moderate altitudes, which are easily accessible, offer, to all experimental evidence, a perfect conducting path, better than a copper wire, for currents of this character.

Thus the discovery of these new properties of the atmosphere not only opened up the possibility of transmitting, without wires, energy in large amounts, but, what was still more significant, it afforded the certitude that energy could be transmitted in this manner economically. In this new system it matters little—in fact, almost

nothing—whether the transmission is effected at a distance of a few miles or of a few thousand miles.

While I have not, as yet, actually effected a transmission of a considerable amount of energy, such as would be of industrial importance, to a great distance by this new method, I have operated several model plants under exactly the same conditions which will exist in a large plant of this kind, and the practicability of the system is thoroughly demonstrated. The experiments have shown conclusively that, with two terminals maintained at an elevation of not more than thirty thousand to thirty-five thousand feet above sea-level, and with an electrical pressure of fifteen to twenty million volts, the energy of thousands of horse-power can be transmitted over distances which may be hundreds and, if necessary, thousands of miles. I am hopeful, however, that I may be able to reduce very considerably the elevation of the terminals now required, and with this object I am following up an idea which promises such a realization. There is, of course, a popular prejudice against using an electrical pressure of millions of volts, which may cause sparks to fly at distances of hundreds of feet, but, paradoxical as it may seem, the system, as I have described it in a technical publication, offers greater personal safety than most of the ordinary distribution circuits now used in the cities. This is, in a measure, borne out by the fact that, although I have carried on such experiments for a number of years, no injury has been sustained either by me or any of my assistants.

But to enable a practical introduction of the system, a number of essential requirements are still to be fulfilled. It is not enough to develop appliances by means of which such a transmission can be effected. The machinery must be such as to allow the transformation and transmission of electrical energy under highly economical and practical conditions. Furthermore, an inducement must be offered to those who are engaged in the industrial exploitation of natural sources of power, as waterfalls, by guaranteeing greater returns on the capital invested than they can secure by local development of the property.

From that moment when it was observed that, contrary to the established opinion, low and easily accessible strata of the atmosphere are capable of conducting electricity, the transmission of electrical energy without wires has become a rational task of the engineer, and one surpassing all others in importance. Its practical consummation would mean that energy would be available for the uses of man at any point of the globe, not in small amounts such as might be derived from the ambient medium by suitable machinery, but in quantities virtually unlimited, from waterfalls. Export of power would then become the chief source of income for many happily situated countries, as the United States, Canada, Central and South America, Switzerland, and Sweden. Men could settle down everywhere, fertilize and irrigate the soil with little effort, and convert barren deserts into gardens, and thus the entire globe could be transformed and made a fitter abode for mankind. It is highly probable that if there are intelligent beings on Mars they have long ago realized this very idea, which would explain the changes on its surface noted by astronomers. The atmosphere on that planet, being of considerably smaller density than that of the earth, would make the task much more easy.

It is probable that we shall soon have a self-acting heat-engine capable of deriving moderate amounts of energy from the ambient medium. There is also a possibility—though a small one—that we may obtain electrical energy direct from the sun. This might be the case if the Maxwellian theory is true, according to which electrical vibrations of all rates should emanate from the sun. I am still investigating this subject. Sir William Crookes has shown in his beautiful invention known as the "radiometer" that rays may produce by impact a mechanical effect, and this may lead to some important revelation as to the utilization of the sun's rays in novel ways. Other sources of energy may be opened up, and new methods of deriving energy from the sun discovered, but none of these or similar achievements would equal in importance the transmission of power to any distance through the medium. I can conceive of no technical advance which would tend to unite the various elements of humanity more effectively than this one, or of one which would more add to and more economize human energy. It would be the best means of increasing the force accelerating the human mass. The mere moral influence of such a radical departure would be incalculable. On the other hand, if at any point of the globe energy can be obtained in limited quantities from the ambient medium by means of a self-acting heat-engine or otherwise, the conditions will remain the same as before. Human performance will be increased, but men will remain strangers as they were.

I anticipate that many, unprepared for these results, which, through long familiarity, appear to me simple and obvious, will consider them still far from practical application. Such reserve, and even opposition, of some is as useful a quality and as necessary an element in human progress as the quick receptivity and enthusiasm of others. Thus, a mass which resists the force at first, once set in movement, adds to the energy. The scientific man does not aim at an immediate result. He does not expect that his advanced ideas will be readily taken up. His work is like that of the planter—for the future. His duty is to lay the foundation for those who are to come, and point the way. He lives and labors and hopes with the poet who says:

Schaff', das Tagwerk meiner Hände,
Hohes Glück, dass ich's vollende!
Lass, o lass mich nicht ermatten!
Nein, es sind nicht leere Träume:
Jetzt nur Stangen, diese Bäume
Geben einst noch Frucht und Schatten.[1]

[1] Daily work—my hands' employment,
To complete is pure enjoyment!
Let, oh, let me never falter!
No! there is no empty dreaming:
Lo! these trees, but bare poles seeming,
Yet will yield both fruit and shelter!
Goethe's "Hope,"
Translated by William Gibson, Com. U. S. N.

Mr. Tesla's Announcements.

IT is well known that for many years Mr. Tesla has been addressing himself to the largest problems connected with the increase of human energy by electrical means, and in the eyes of the great number of eager investigators in the general field of electricity this fact will give piquancy to the important narrative of his work which he contributes to the present number of THE CENTURY. Happily, the paper is addressed also to the comprehension of the untechnical reader, who will find some of the ideas and results there set forth little short of the incredible. In general, much that must seem speculative to the layman can take its proper place only in the purview of the scientist, who knows what a part the imagination has played both as a forerunner and as a stimulus of discovery. In Sir Isaac Newton's day no doubt there were wiseacres who would have considered that eminent "dreamer" much more worthy of their respect if the fall of the historic apple had suggested to him not a mere trifle like the law of gravita-

tion, but some new and important device in cider-mills. The dullest observer is not likely to blink the practical bearings of Mr. Tesla's paper on manufactures, mining, invention, agriculture, commerce, transportation, war—in short, on modern life itself.

For the general reader, Mr. Tesla does what he confesses the author of "The Intellectual Development of Europe" did for him—namely, presents a new and never-to-be-forgotten conception of humanity moving as a mass. To follow his vivid introduction is like looking down from a great height and seeing familiar and new regions in their true relationship. It begets the feeling of being a spectator at the progress of the world, of listening to the grandest of symphonies. It awakens in one a new interest in his fellow-men and a sobering and devout sense of his relation to the universe, helping him to realize the poet's vision:

> One God, one law, one element,
> And one far-off divine event,
> To which the whole creation moves.

Human Energy Increased.—Once again we hear of remarkable inventions and aspirations from Mr. Nikola Tesla. This time the problem which occupies his attention is that of increasing human energy, and his views are published in the *Century Magazine*. He gives three ways in which his problem may be solved—namely, "to increase the human mass," "to reduce the retarding force," and "to increase the impelling force." The first is accomplished by attention to hygiene and good food. Ignorance and stupidity form a retarding force that people are continually endeavouring to improve out of existence, but there are other retarding forces, the greatest being warfare, and to overcome some of these the writer invented the telautomaton, "a machine having all its bodily or translatory movements and the operations of the interior mechanism controlled from a distance without wires." The possibilities of this machine are amazing, "and the continuous development in this direction must ultimately make war a mere contest of machines without men and without loss of life." The third problem—"how to increase the force accelerating the human mass"—is to be solved by the application of the power of the sun. Wireless telephony and wireless electrical power transmission are also among the castles which Mr. Tesla has built in the air.

SCIENTIFIC

Mr. Tesla's Experiments

The Problem of Increasing Human Energy is the title of an article in the June *Century,* by Nicola Tesla, the inventor. Mr. Tesla gives us glimpses of many of his recent experiments, having in view the increase of human energy, but a very small part of the article is intelligible to the lay reader, and it is, furthermore, largely speculative. Below we quote a part of the article describing the discovery of some new properties of the atmosphere and interesting experiments made by Mr. Tesla in connection therewith:

I was led to recognize the transmission of electrical energy to any distance through the media as by far the best solution of the great problem of harnessing the sun's energy for the uses of man. For a long time I was convinced that such a transmission on an industrial scale could never be realized, but a discovery which I made changed my view. I observed that under certain conditions the atmosphere, which is normally a high insulator, assumes conducting properties, and so becomes capable of conveying any amount of electrical energy. But the difficulties in the way of a practical utilization of this discovery for the purpose of transmitting electrical energy without wires were seemingly insuperable. The work required patience and constant application, but the improvements came, though slowly. Other valuable results were, however, arrived at in the course of this long-continued work, of which I shall endeavor to give a brief account, enumerating the chief advances as they were successively effected.

The discovery of the conducting properties of the air, though unexpected, was only a natural result of experiments in a special field which I had carried on for some years before. It was, I believe, during 1889 that certain possibilities offered by extremely rapid electrical oscillations determined me to design a number of special machines adapted for their investigation. One of the earliest observations I made with these new machines was that electrical oscillations of an extremely high rate act in an extraordinary manner upon the human organism. Thus, for instance, I demonstrated that powerful electrical discharges of several hundred thousand volts, which at that time were considered absolutely deadly, could be passed through the body without inconvenience or hurtful consequences. I still remember with pleasure how, nine years ago, I passed the discharge of a powerful induction-coil through my body to demonstrate before a scientific society the comparative harmlessness of very rapidly vibrating electric currents, and I can still recall the astonishment of my audience. I would now undertake, with much less apprehension than I had in that experiment, to transmit through my body with such currents the entire electrical energy of the dynamos now working at Niagara—forty or fifty thousand horse-power. I have produced electrical oscillations which were of such intensity that when circulating through my arms and chest they have melted wires which joined my hands, and still I felt no inconvenience.

Another observation was that by means of such oscillations light could be produced in a novel and more economical manner, which promised to lead to an ideal system of electric illumination by vacuum-tubes, dispensing with the necessity of renewal of lamps or incandescent filaments, and possibly also with the use of wires in the interior of buildings. The efficiency of this light increases in proportion to the rate of the

oscillations, and its commercial success is, therefore, dependent on the economical production of electrical vibrations of transcending rates. In this direction I have met with gratifying success of late, and the practical introduction of this new system of illumination is not far off.

The investigations led to many other valuable observations and results, one of the more important of which was the demonstration of the practicability of supplying electrical energy through one wire without return. At first I was able to transmit in this novel manner only very small amounts of electrical energy, but in this line also my efforts have been rewarded with similar success. To what a degree the appliances have been perfected since my first demonstrations early in 1891 before a scientific society, when my apparatus was barely capable of lighting one lamp (which result was considered wonderful), will appear when I state that I have now no difficulty in lighting in this manner four or five hundred lamps, and could light many more. In fact, there is no limit to the amount of energy which may in this way be supplied to operate any kind of electrical device.

After demonstrating the practicability of this method of transmission, the thought naturally occurred to me to use the earth as a conductor, thus dispensing with all wires. Whatever electricity may be, it is a fact that it behaves like an incompressible fluid, and the earth may be looked upon as an immense reservoir of electricity, which, I thought, could be disturbed effectively by a properly designed electrical machine. Accordingly, my next efforts were directed toward perfecting a special apparatus which would be highly effective in creating a disturbance of electricity in the earth. The progress in this new direction was necessarily very slow and the work discouraging, until I finally succeeded in perfecting a novel kind of transformer or induction-coil, particularly suited for this special purpose. It is practicable, in this manner, not only to transmit minute amounts of electrical energy for operating delicate electrical devices, as I contemplated at first, but also electrical energy in appreciable quantities.

NOTES.

THE sensational announcements in the American press with regard to Mr. NIKOLA TESLA'S wonderful doings and still more wonderful prophecies, have been attributed in a large measure to the highly developed power of imaginative embroidery possessed by some Western newspaper reporters. An article by Mr. TESLA himself, in the current number of the *Century Magazine*, shows that an injustice has been done to that class of individuals, for this contribution equals in wild speculation anything hitherto attributed to the eminent inventor. The article is headed "The Problem of Increasing Human Energy, with Special Reference to the Harnessing of the Sun's Energy." The writer begins by postulating that human life is a movement. The existence of a body in motion unavoidably implies a force which is moving it. Consequently Mr. TESLA chooses to consider human energy as denotable by the expression $MV^2/2$, and proceeds to consider how it may be increased. M he takes as the "total mass of man in the ordinary interpretation of the term 'mass,'" and V is "a certain hypothetical velocity." He warns his readers against reducing their mass by intemperance, impure drinking water, or laxity of morals—digressing on the subject of food supply, and the production of artificial

fertilisers by causing the nitrogen of the air to combine chemically with the oxygen in a high-pressure electric discharge.

ORGANISED warfare, Mr. TESLA thinks, is what tends mostly to the reduction of the hypothetical velocity V, and he proceeds to describe a means, he has not yet perfected, of rendering warfare less harmful in this direction. This simple means is the substitution of "telautomatics" for men. So far he has only succeeded in constructing one such apparatus—a boat controlled by electrical oscillations—with a "borrowed mind"; but, he says "I purpose to show that, however impossible it may now seem, an automaton may be contrived which will have its 'own mind' and . . . be capable of distinguishing between what it ought to do and what it ought not to do. . . . . In fact, I have already conceived such a plan." On the other hand, to deal fully with the methods of increasing the force "accelerating the human mass" would lead Mr. TESLA too far. "Suffice it to state that the resultant of all these forces is always in the direction of reason. . ." A "telautomatic" is then presumably not one of the components.

LACK of space precludes us also from dealing more fully with Mr. TESLA'S dreams—or are they nightmares?—with their bright pictures of high-pressure phenomena. We can only mention briefly some of his schemes for the advantage of mankind. He intends to smelt iron by first electrolysing water, burning the hydrogen in air to produce the heat for smelting, and selling the pure oxygen as a by-product. He suggests other methods than windmills of obtaining energy from "the ambient medium," some of which he no longer considers likely to be commercially profitable, and others with regard to which he is more hopeful. He next deals with the transmission of energy through space without wires. The proposal to transmit electricity at high pressure through the upper strata of the atmosphere we have alluded to on a former occasion, but the following bears repetition. Mr. TESLA has discovered causes of error in HERTZ'S researches, with the result that he has "long ago ceased to look upon his [HERTZ'S] results as being an experimental verification of the poetical conceptions of MAXWELL."

TESLA ON ENERGY.

By T. H. MURAS.

IN the *Century Magazine* for June there appears an article of 36 pages by Nikola Tesla on "The Problem of Increasing Human Energy, with Special Reference to the Harnessing of the Sun's Energy." Human energy here means the total power available to humanity. Increase of it is to be obtained in the first place by adding to and improving the condition of humanity, and for this purpose the author emphasises the necessity of increasing the productivity of the soil. He states: "the key for the solution of the all-important food problem" to be the cheap production of compounds of nitrogen to replace that withdrawn from the soil by crops, and proposes to produce such compounds by the use of electric discharges of high frequency in air, and, in fact, to develop Cavendish's experiment on the production of nitric acid into a manufacture. The necessary electrical energy is to be obtained from waterfalls. In this proposal the author appears to suffer from the incomplete knowledge with which a scientific man is sometimes unconsciously afflicted when he looks over the paling surrounding the little scientific plot that he has laboriously cultivated. Mr. Tesla does not mention, and apparently is unaware of the fact, that any necessary amount of nitrogen can be "fixed" in the soil by the prosaic agricultural method of growing leguminous plants, such as clover, as one of the crops in a rotation, these co-operating with special bacteria, which fix and supply nitrogen to their roots by means of energy derived in carbon compounds from the plants. In this practically simple process the energy used is obtained by the plant directly from the sun's radiation, and to anyone whose vision is not absolutely bounded by the walls of a laboratory, the proposed production of nitrogen compounds by the waterfall and electric method must appear a very crude substitute. It is true that agricultural methods are inefficient in various ways, and especially as regards the proportion of the sun's available power utilised; but this appears comparatively unimportant, in view of the almost unlimited supply of such power. It would appear to a commonplace individual that patient work in the scientific study of such bacteria and crops, with a view to their more efficient working, with the help of artificial selection or otherwise, is a far more promising "key for the solution of the all-important food problem" than any new method at present in prospect for obtaining human energy from the sun's radiation or otherwise.

In the second place, Tesla proposes to substitute mechanical automata, more or less controlled by high frequency electromagnetic radiations, for human beings in warfare. Judging from recent events, the supply of "human energy" for this purpose does not appear to be limited, in this country at any rate; the real demand appears to be for an outlet for existing energy, and warfare in South Africa is preferred to office work in England.

The remainder of the article contains a number of suggestions as to obtaining energy for mechanical and chemical purposes directly from sunlight, and from the heat of the earth and atmosphere; and its transmission by high frequency electric currents through the upper part of the atmosphere. The article does not contain one exact measurement or statement of an attained result, but it is accompanied by photographs of remarkable electric discharges, extending to 100 feet long, in the air. These are apparently obtained by high frequency currents in large inductive circuits, tuned by means of condensers to rates from 50,000 to 130,000 ~ per second, the pressure obtained being about 12 million volts! No indication is given as to how these figures are arrived at, but Mr. Tesla is obviously not a believer in the hypothesis (based on experiments) that a pressure much exceeding 100,000 volts cannot exist between any two conductors at any distance apart in air, on account of discharge occurring in brush or "spark" form. Electricians, and probably other people, would have been grateful if a few pages of the article had been devoted to a precise account of these electrical experiments, especially as his experiments have caused Mr. Tesla to state, relative to the work of Hertz, "I have long since ceased to look upon his results as being an experimental verification of the poetical conceptions of Maxwell." As it is, the article is mainly of interest on account of the pretty and somewhat startling photographs.

DIRECT APPLICATION OF ELECTRICITY TO THE PROPULSION OF SHIPS.

A Reply to Certain of the Statements Made by Nikola Tesla in the June, 1900, Issue of "The Century Magazine."

BY WILLIAM F. DURAND.

In the June number of *The Century Magazine* is found an article from the pen of Mr. Nikola Tesla, in which the author discusses in a decidedly transcendental manner the problem of "increasing human energy." It would not be difficult to join issue with Mr. Tesla regarding some of the fundamental assumptions made, as for example, that *mechanical energy,* expressible by formula $MV^2 \div 2$, or in terms of mass and velocity as we know them, can fully represent the quality of the operations of the human mind. This is simply begging a question regarding which we are profoundly ignorant, a question regarding which we have no sure facts, and therefore in regard to which it is in the last degree unscientific to make the assumptions implied by the author.

The chief interest lies, however, with the transcendental and hypothetical conclusions drawn from these assumptions, and among them are found two or three relative to the application of electricity to marine propulsion. These conclusions are utterly incorrect and in direct antagonism with the laws of nature, and taking into account the standing in literary circles usually accredited to *The Century Magazine* and the popular reputation as an electrician usually accredited to the author, it would seem proper to point out the nature of these errors, lest by those not technically qualified to judge, such absurdities might be considered as having some foundation in fact.

On page 198 are found the following statements:

> Instead of driving the machinery in a factory in the old wasteful way by belts and shafting, we generate electricity by steam power and operate electric motors. In this manner it is not uncommon to obtain two or three times as much effective motive power from the fuel, besides securing many other important advantages. It is in this field as much as in the transmission of energy to great distances that the alternating system, with its ideally simple machinery, is bringing about an industrial revolution. But in many lines this progress has not yet been felt. For example, steamers and trains are still being propelled by the direct application of steam power to shafts and axles. A much greater percentage of the heat-energy of the fuel could be transformed in motive energy by using, in place of the adopted marine engines and locomotives, dynamos driven by specially designed high-pressure steam or gas-engines, and by utilizing the electricity generated for propulsion. A gain of fifty to one hundred per cent in the effective energy derived from the coal could be secured in this manner. It is difficult to understand why a fact so plain and obvious is

> not receiving more attention from engineers. In ocean steamers such an improvement would be particularly desirable, as it would do away with noise and increase materially the speed and the carrying capacity of the liners.

It is more especially with respect to the latter part of the quotation that we are here concerned. The proposition in brief is to displace the usual type of marine engine by "specially designed high-pressure steam or gas engines," driving electric generators, the electrical energy thus developed being then carried to an electric motor attached to the propeller shaft. In other words, an electric generator and motor are to be interposed between the engine and the propeller-shaft. Now let us examine this proposition, regarding the likelihood of an increase of efficiency similar to that promised in the quotation given above.

In the first place not the slightest grain of superiority or improvement in efficiency due to the use of the "specially designed high-pressure steam or gas engine will be conceded. Any such motor which can be used to operate an electric generator can also be used to operate a propeller direct, and without the interposition of the generator and motor. Screw propellers are designed and operated at speeds of revolution from 100 per minute and less to 2,000 per minute and over, and as an instrument of propulsion it is as fully capable of utilizing any gain in the efficiency of the prime-mover as is an electric generator. In any event the use of a screw propeller is assumed, and it is evident that it will be an element of equal value in either scheme of powering and propulsion.

Further, as to the high pressure steam engine, where shall we find anything higher than the 300 to 400 lbs., which is accepted and involved in present day practice with torpedo boats, fast launches, yachts and cruisers? Again, with regard to engine efficiency, where in present practice shall we go to better the record of the S. S. *Kensington*, 8,000 I. H. P., with her service record of about 1.00 lb. of coal per I. H. P. for the main engines? Again, regarding gas engines on board ship, the weight which present practice seems to find necessary for their safe construction and efficient operation is entirely prohibitive of their use when the highest results are to be attained. Then as a practical problem how would a designer of gas engines like to undertake the design and guarantee performance of a gas engine of, say, 10,000 I. H. P.? Or if, otherwise, such total power were to be split up into a number of small units the whole scheme immediately breaks down by reason of its complexity and weight. Then there is the further question of the cost of gasoline or other hydrocarbon, and of the enormous increase of output which would be required in order to make possible its use on any large scale; or if the gas is to be made from coal, is each ship to carry gas works in the fore hold, or is the gas to be stored in the bunkers and double bottoms?

All these considerations of detail, however, are beside the main point, which, as already noted, is that no claim of superiority whatever can be admitted for the use of any special type of prime-mover, since for utilizing the increased efficiency of any such improved steam or gas engine, the propeller is quite as capable as the electric generator.

The question simplifies therefore to the following: Given two steam engines or other prime-movers of equal efficiency, to compare the two schemes for ship propulsion in one of which the prime-mover is attached directly to the propeller shaft; and in the other, of which there is interposed between the two an electric generator and motor. If the gain of from 50 to 100 per cent promised by Mr. Tesla is to be realized at all, it must therefore come in as a result of these additional transformations of energy. Now, one of the first things which the engineer learns in his dealings with energy is that all transformations are sources of loss. This is a fact so simple and so fundamental that it cannot be overlooked, least of all by one who has given his life to the study of problems involving the transformation and use of energy in various forms. Yet here we find a proposition to interpose between the steam engine and the propeller two transformations or changes of energy, one from the mechanical form in the engine to the electrical form in the generator, and the other a change back to the mechanical form in the motor. There will also be a further loss due to transmission from the generator to the motor, but on board ship this will be very small and may be neglected. Taking as a basis of estimate the actual achievements of electrical engineering at the present day, the best combined efficiency which could be expected for this double transformation would be perhaps 90 per cent, though probably 85 per cent might be a safer estimate. In other words, of the energy supplied by the steam engine from 10 to 15 per cent would be lost as a result of the electrical transformations. So to take the more favorable case, for every 100 horse power delivered by the engine, 90 will reach the shaft instead of 100 as in the case of direct connection between engine and propeller. Yet to these transformations of energy which by the law of the conservation of energy must result in a loss, we are to look, if anywhere, for a gain of from 50 to 100 per cent, so that in the preceding case instead of 90 delivered horse power or thereabouts, as would actually be the case, we are to look for from 150 to 200. This would mean simply the creation of energy, and is a dream of perpetual motion in its baldest form. Such a proposition is a not unworthy fellow to those which have but recently been put before the public in connection with the liquid air absurdities.

Mr. Tesla knows, however, too well the doctrine of the conservation of energy to base any expectation of gain upon transformations which he knows must give rise to a loss, and it is therefore only fair to assume that his faith was pinned to the gain expected from the "specially designed high-pressure steam or gas engine," a gain which would reduce the cost of power in terms of fuel to one-half or two-thirds of the figures representing the best present practice. This especially designed engine would apparently also be of such peculiar type that while available for operating an electrical generator it could not be used for turning a screw-propeller. It may perhaps be in order to suggest that the design for such a prime-mover should be forthcoming in order to substantiate the claim, and until such an engine is produced all such claims for possible gain must be considered as without foundation, and instead of gain there is the certainty of loss. There may also have been some

expectation of gain by a shortening of the line shafting, or in greater uniformity of turning effort in the propeller. There is ground for expecting small gains due to these features, but so small as to be utterly inconsiderable and without practical influence on the main features of the problem. These points only merit mention in order that all sources of gain for the electrical scheme may be noted.

The author's naive curiosity as to why a method which promises so great a saving should have received so little attention from engineers is at the least amusing. Does he suppose that marine engineers are ignorant of the trend of advancement in the electrical field? Does he suppose that if there were any reasonable hope of increasing the efficiency by 50 to 100 per cent that it would not receive some attention from those most interested? If there were any likelihood of cutting the consumption of coal per day on a "liner" from, say, 400 tons to 200 or 275; that is a saving from 125 to 200 tons per day, and of increasing the cargo capacity by perhaps 1,000 tons for the trip, would those most interested long delay the adoption of such means? The truth seems to be that this so-called "fact," plain and obvious as it may seem to Mr. Tesla, is less plain and less obvious to those who are actually doing the world's work in the field of marine design and construction. If there is any one fact that is plain and obvious to them it is that a multiplication of changes of energy means a loss, and the proposition to interpose additional changes between the prime-mover and the propeller will be apt to receive from them small consideration so long as the laws of nature remain as they now are.

There is still another interesting side to this proposition, and that is, the price which must be paid for the apparatus; that is, for the generators and motors. The first point to be made is that the price is two-fold; one the price in terms of money, and the other the price in terms of weight.

If we confine ourselves to actual achievement in electrical engineering we shall hardly find builders of generators and motors ready to guarantee results for much less than 20 to 30 lb. per H. P., and these figures will require most careful design and might easily rise to 50 lb. and over. The installation of generators and motors will therefore mean the addition of, say, 50 lb. and upward per H. P. This would just about double the weight of machinery on a modern torpedo boat, for which in recent practice the engines and boilers together weigh 50 lb. or less per I. H. P. Let us compare the figures for a torpedo boat with 3,000 I. H. P.:

	STEAM EQUIPMENT.	STEAM AND ELECTRICAL EQUIPMENT.
Hull	56 tons	56 tons.
Coal, ordnance and stores	37 "	37 "
Machinery	67 "	134 "
Total	160	227

The displacement of the boat would thus be increased by about 67 tons, or from 160 to 227, while the power delivered to the propeller shaft would be decreased by, say, 300 H. P. The joint effect of these would be a reduction in the speed of the boat by about 3 knots, or from, say, 25 knots to 22. These results are hardly such as would be apt to commend themselves to naval designers.

Again, with a "liner" having, say, 25,000 I. H. P., the addition of electrical machinery of suitable type would result in adding perhaps 1,500,000 lb., or about 700 tons to the machinery weights. For the same total displacement this would mean the loss of about 700 tons of paying cargo, and a further loss of about 2,500 horse power as a result of the electrical transformations, decreasing the speed by from 1-2 to 3-4 knot. When we remember that on the modern "liner" the margin of weight left for paying cargo is quite small, usually not exceeding a maximum of 2,000 tons, it is apparent that the loss of 700 tons or more would result in a most serious reduction in the earning capacity of the vessel. The "increase" of carrying capacity referred to at the close of the quotation would be therefore of a character not likely to commend itself to the stockholders or board of directors.

The price to be paid in cash will depend on the current prices for electrical machinery of such types and sizes as may be required, but it will not be far wrong to say that the cost of the electrical equipment would be not less than that of the steam equipment, and that the cost of the total equipment would therefore be not less than double what it is with the present methods of powering and propulsion. The interest on this added first cost would make a most serious inroad upon the small margin of profit now obtainable from investments in this field of commerce.

A passing reference may also be made to the statements in the early part of the quotation relating to the substitution of electric generators and motors for lines of shafting and belting, whereby it is claimed that two or three times as much effective power may be obtained as by the old and wasteful methods. From what has preceded it is clear that the substitution of electric generators and motors for shafting and belting is a substitution of one form of loss for another, and the final balance will depend on which is the greater of the two. If the belting and shafting scheme is long and complicated and perhaps in poor mechanical condition as well, there will undoubtedly result a gain in efficiency for the electrical scheme. If it is short and direct and in good condition, the advantage will remain with the mechanical transmission. In no normal or ordinary case, however, will the gain amount to anything approaching 100 to 200 per cent. In fact, the question of fuel economy in such cases is only one of many considerations, and not always the most important. In cases where such installations have been made it is probable that other considerations have weighed quite as much as that of economy of fuel. Among such special advantages for the electrical scheme are the following: Independence of operation, entire freedom in locating machines without reference to lines of shafting, etc., absence of line shafting, countershafts, etc., and consequent greater freedom for the operation of cranes and handling gear.

not of a translatory character, yet the general laws of mechanical movement are applicable to it;" "That we can send a message to a planet is certain, that we can get an answer is probable;" "It is highly probable that if there are intelligent beings on Mars they have long ago realized this very idea [the transmission of electrical energy for industrial purposes without wires], *which would explain the changes on its surface noted by astronomers.*" (The italics are our own.)

Mr. Tesla's doctrine of human energy is in some ways as original as the inventions and discoveries which he expects to make. Each of us is, he says, a part of a unitary whole, 'man.' "This one human being lives on and on. . . . Therein . . . . is to be found the partial explanation of many of those marvelous phenomena of heredity which are the result of countless centuries of feeble but persistent influence." Now we may "assume that human energy is measured by half the product of man's mass with the square of a certain hypothetical velocity. . . . . the great problem of science is, and always will be, to increase the energy thus defined. . . . This mass is impelled in one direction by a force F, which is resisted by another partly frictional and partly negative force R, acting in a direction exactly opposite, and retarding the movement of the mass."

Unhappily Mr. Tesla in his enthusiasm to progress to recommendations of religion, vegetarianism, the old régime for women and the artificial preparation of nitrogen compounds, neglects to state which direction is the proper one for the human mass to follow, north, south, east, west, toward the moon or Sirius or to Dante's Satan in the centre of the earth. Nor does he explain how 'enlightenment' makes the mass of human bodies go in an exactly opposite direction to that toward which 'visionariness' impels them, nor reveal why, if his account be true, he and a 'visionary' can walk in the same direction. Of course the whole notion that the 'velocity' of the human 'mass,' *i.e.* the space it traverses in a given time, has any connection with human progress or is of any value to anybody or anything, is absurd.

Mr. Tesla has enjoyed considerable, excellent repute as a gifted student of certain electrical phenomena and one expects a good deal from his "electrical experiments, now first published." Mr. Tesla, too, expects a good deal from them. It would take too long to even note here all the important scientific discoveries which Mr. Tesla expects to make or all the benefits which he expects to thereby confer upon mankind in general and in particular upon those who exploit his inventions. Some samples may be given. War will be rendered harmless by being reduced to a sort of game between 'telautaumata,' machines which behave "just like a blind-folded person obeying instructions received through the ear," any one of which is "enabled to move and to perform all its operations with reason and intelligence."

Says Mr. Tesla: "I purpose to show that, however impossible it may now seem, an automaton may be contrived which will have its 'own mind,' and by this I mean that it will be able, independent of any operator, left entirely to itself, to perform, in response to external influences affecting its sensitive organs, a great variety of acts and operations as if it had intelligence. It will be able to follow a course laid out or to obey orders given far in advance; it will be capable of distinguishing between what it ought and what it ought not to do, and of making experiences or, otherwise stated, of recording impressions which will definitely affect its subsequent actions. In fact, I have already conceived such a plan."

Inasmuch as the interest in this telautomatic warfare is to be purely æsthetic, it would seem as if international bull-fights or kite-flying or spelling matches or potato-races might do as well, and have the added advantage of leaving Mr. Tesla's expectations free to wander among the following prospective discoveries.

New sources of energy, Mr. Tesla thinks, may be opened up, such as a wheel which shall perform work without any further effort on our part than that of constructing it. "Imagine a disc of some homogeneous material turned perfectly true and arranged to turn in frictionless bearings on a horizontal shaft above the ground. This disk, being under the above conditions perfectly balanced, would rest in any position. Now, it is possible that we may learn how to make such a disk rotate continuously and perform work by the force of gravity without any further effort on our part. . . . . To make the disk rotate by the force of gravity we have only to invent a screen against this force. By such a screen we could prevent this force from acting on one half of the disk, and the rotation of the latter would follow."

Into further particulars concerning the nature of such a screen Mr. Tesla does not enter, though it would seem a matter well fitted to engage his peculiar gifts. The 'screen against gravity' idea has already entered into a popular story, but scientific men have probably not given it much consideration.

By producing a 'sink' or reservoir of a low temperature, thereby inducing the heat of the ambient medium to transform itself in part into other forms of energy *(e.g.* electrical), Mr. Tesla hopes to "get any amount of energy without further effort" beyond the amount needed to create the 'sink.' We should thus employ "an ideal way of obtaining motor power," and incidentally rebuke the narrow-minded physics of Carnot and Lord Kelvin.

By means of his electrical oscillator Mr. Tesla has satisfied himself that he can transmit electrical energy in large quantities without wires. He expects that this can be done to great economic advantage. Then would come the golden age. "Men could settle down everywhere, fertilize and irrigate the soil

SCIENCE AND FICTION.

The leading article of the June number of the *Century Magazine* is entitled "The Problem of increasing Human Energy," and is written by Nikola Tesla. Mr. Tesla offers the reader some naive verbal analogies between the causes of human progress and the 'energy' of theoretical physics, and a eulogy of a number of inventions which he expects to make. He intersperses these with sundry remarkable statements such as, "our own earth will be a lump of ice;" "Though this movement is

with little effort, and convert barren deserts into gardens, and thus the entire globe could be transformed and made a fitter abode for mankind."

The golden age figures largely in Mr. Tesla's article; he offers us all that is entrancing and wonderful. He is generous. We ask for the bread of definite facts of science and intelligible evidence, but he gives us the amethyst and topaz and diamonds of an ambient medium doing all our work and the atmosphere transporting all our motive power and the tyrant gravity held powerless by a screen, and Mr. Tesla correcting Lord Kelvin's errors. Still amethyst and topaz and diamonds are only stones. They may dazzle the magazine reader, but they do not nourish the student of science.

The editorial department of the *Century Magazine* perhaps felt that these jewels were a bit too bright. We read there that "much that must seem speculative to the layman can take its proper place only in the purview of the scientist." Some conservative scientists will feel like growling, "And much that must seem bosh to the man of science can take its proper place only in the purview of the editorial departments of popular magazines." Leaving aside the present case, it is a fact that the same care which is exercised by editors to secure in their contributions excellence of style and syntax, a proper moral tone and freedom from advertisement of business ventures, is not exercised to secure accuracy in statements of fact or decent credibility in matters of theory. The editors apparently impute to their readers a desire to be entertained at all costs. They descend to a footing with the Sunday newspaper instead of trying to rise to the level of such scientific literature as Huxley or Tyndall gave us. They evidently often do not know science from rubbish and apparently seldom make any effort to find out the difference. They should at least submit their scientific literature to competent men for criticism and revision.

The general public is helpless before any supposedly scientific statement. It may judge vaguely by the standing of the paper or magazine or book containing it, by the name of the writer or by the general tone in which the article is written. But it cannot judge definitely by comparison with relevant facts or by critically examining the logic of the deductions, for the general public lacks both knowledge of the relevant facts and training in logical criticism. That a man should invent a microscope which will enable one to see objects a million times as small as can be seen with the naked eye seems no more questionable to the general public than that a man should cause unfertilized eggs to develop. Yet the first would be impossible while the second has been possible, probable, and still more lately proved. Guidance in scientific matters should be welcome if only for the protection thus given against fraudulent medicines, bogus inventions and nonsensical enterprises.

PHYSICIST.

Tesla and the Electric Propulsion of Ships.—In a recent number of the "Century Maganzine" an article by Mr. Nikola Tesla was printed, in which some statements were made that drew caustic comment from our contemporary, "Marine Engineering." In the July number of the latter magazine the editor refers to the article as the "handiwork of a cerebrose individual * * * a bombastical genius who has illumined unknown fields of imaginative science with his intellectual searchlight and is willing to permit the gaping world of ignorance or complaisance to peep in and wonder, the credulous editor drawing the curtain. This dazzling contribution to modern unscientific research," he continues, "reads like nothing so much as an essay on Christian Science, so profound is it in the ambiguous nothingness whereby it leads through the intricacies of incoherency into the climax of absolute asininity." The particular statements made by Mr. Tesla which most aroused the editor of "Marine Engineering" were:

"Steamers and trains are still being propelled by direct application of steam power to shafts and axles. A much greater percentage of the heat energy of the fuel could be transformed in motive energy by using in place of the adopted marine engines and locomotives, dynamos driven by specially-designed high-pressure steam engines or gas engines, and by utilizing the electricity generated for the propulsion. A gain of from 50 to 100 per cent in the effective energy derived from the coal could be secured in this manner. In ocean steamers such an improvement would be particularly desirable as it would do away with noise and increase materially the speed and carrying capacity of the liners."

In the same issue of "Marine Engineering" also appears an article by Prof. W. F. Durand commenting upon Mr. Tesla's reckless statement. Mr. Durand argues, and of course soundly, that any especially efficient prime mover which can be used to drive an electric generator can also be used to drive a propeller direct so that interposing a generator and motor between the prime mover and the propeller shaft would be a gratuitous waste of energy. Mr. Durand further points out that the addition of an electrical equipment in the case of a liner having 25,000 horse-power of driving machinery would result in a loss of about one-third of the freight-carrying capacity of the ship, besides the loss of about 2500 horse-power due to the two transformations of energy, entailing a reduction in speed from half to three-quarters of a knot. "The increase of carrying capacity referred to at the close of the quotation," says Mr. Durand, "would be, therefore, of a character not likely to commend itself to the stockholders or board of directors."

ELECTRICITY A CURE FOR TUBERCULOSIS

Wonderful Results Said To Have Been Effected by Means of Tesla's Oscillator.

TOLD OF THEIR CURES

Physician and Clergyman at Dr. Carroll's Clinic Declared Treatment Had Saved Them.

Current Thus Applied, It Is Said, Does Not Produce Death, Because Waves Are Synchronous with Life Force.

"Electrical oscillation" as a new treatment for tuberculosis, was demonstrated, and the immediate benefits derived from it by men in the last stages of the disease were testified to at an interesting clinic yesterday in the offices of Dr. Craft C. Carroll, No. 21 East Twenty-fourth street. Dr. Carroll declares that by the application of a new principle evolved by Nikola Tesla he can cure the worst cases of acute tuberculosis. Dr. E. P. Iliff, of Newark, a specialist in lung diseases, who, three weeks ago, was declared to be dying of consumption by his brother physicians, received his third treatment of "electrical oscillation" yesterday at the clinic, and then ran to catch a car on his way back to Newark. The Rev. S. W. Switzer, pastor of the Baptist Tabernacle, in Harrison, N. J., who had been sent to Dr. Carroll in the last stages of consumption, told of his remarkable cure. Dr. John B. Rich, president of the American Microscopical Society, declared that it was the most wonderful demonstration of positive beneficial results that he had ever seen in the treatment of germ diseases.

CHARGE WOULD KILL ORDINARILY.

Nikola Tesla had worked for two years on the apparatus which Dr. Carroll used yesterday in his first public clinic. It was Dr. Carroll's idea to apply the new principle in electricity evolved by Tesla to the treatment of consumption. Mr. Tesla had predicted that oscillation would accomplish wonders, but he had not thought of using it as a germ killer.

By applying the electrode of the Tesla machine, Dr. Carroll drives through the affected part a quantity of electricity, which if applied in any other way would cause instant death. With the Tesla "oscillator" he handles between two and three thousand volts of electricity with impunity. Dr. Carroll says that after the oscillation treatment all tubercular matter is eliminated from the system by the emunctories—the liver, kidneys, bowels and general glandular system. The treatment is one of destruction to the germs.

Dr. Iliff told how he had contracted tuberculosis from his patients about a year ago It had developed in the aorta, which is the artery leading from the heart to the pulmonary system. Stenosis of the aorta resulted. The tubercular matter had clogged the aorta about one inch from the entrance to the heart, so finally the heart could not pump blood to the extremities. A dropsical condition ensued. Dr. Iliff said that in forty-eight hours fo[illegible] weeks ago he increased in weight thirty pounds.

PHYSICIANS HAD GIVEN HIM UP.

"I was removed to Dr. Carroll's office in New York ten days ago," said Dr. Iliff. "My brother physicians protested against my being removed. They said there was not the slightest chance of recovery. They even predicted the hour I was to die. I took my third oscillation treatment to-day. I am now attending to my practice again in Newark and am on the speedy road to complete recovery."

The testimony given by the Rev. Mr. Switzer was almost as remarkable. He had contracted acute tuberculosis four years ago. When he was moved to Dr. Carroll's house the physicians of Newark and Harrison told him he had six weeks to live. He was back attending to his pastoral duties in less than three weeks, and declared yesterday that he had completely recovered.

Henry J. Rice, a patient who had been put under the electrical treatment for the first time on July 9, when he had a respiration of 36, yesterday, it was said, had the full use of his lungs. His respiration was 12. He had had tuberculosis of the lungs for five years. The lower third of the right and left lungs was hepatic. There had been a cavity at the left of the heart bone, so Dr. Carroll said, as large as a silver dollar.

Dr. Carroll says that the cavity has entirely disappeared, and is refilled with new lung tissue

LIFE FORCE ELECTRICAL FORCE.

Asked for an explanation of the treatment, Dr. Carroll said:—

"All life is a force manifestation in which electricity plays a part. Life force, spirit force and electrical force I believe to be one and the same force. Disease or unhealth is only a difference of potential that requires to be brought into a state of equilibrium in order to be brought into a state of health.

"The reason why this high oscillation does not take life is because the wave motions of the machine are in synchronous harmony with the life force in the body."

Dr. Carroll declined to allow the Tesla machine to be seen. All of the apparatus that was visible was the glass electrode, which was spon shaped and hollow. While the current was on there was an opalescent blaze or a series of big sparks in the electrode, which was applied directly to the part affected.

Dr. William F. Holcombe, of No. 78 Lexington avenue, who was present, was unwilling to give a definite opinion as to the treatment until he had attended other clinics.

"Most doctors frown on anything new, but I believe in investigation. It may be that Dr. Carroll has hit on a valuable discovery."

SOME NOVEL INVENTIONS OF NIKOLA TESLA.

BY J. WRIGHT.

Most members of the electrical profession associate the name of Nikola Tesla with high-frequency and high-potential currents, and few are acquainted with the fact that he has also invented several novelties for use in other branches of the profession. It is of some of these extraneous productions that I purpose treating in the course of this paper.

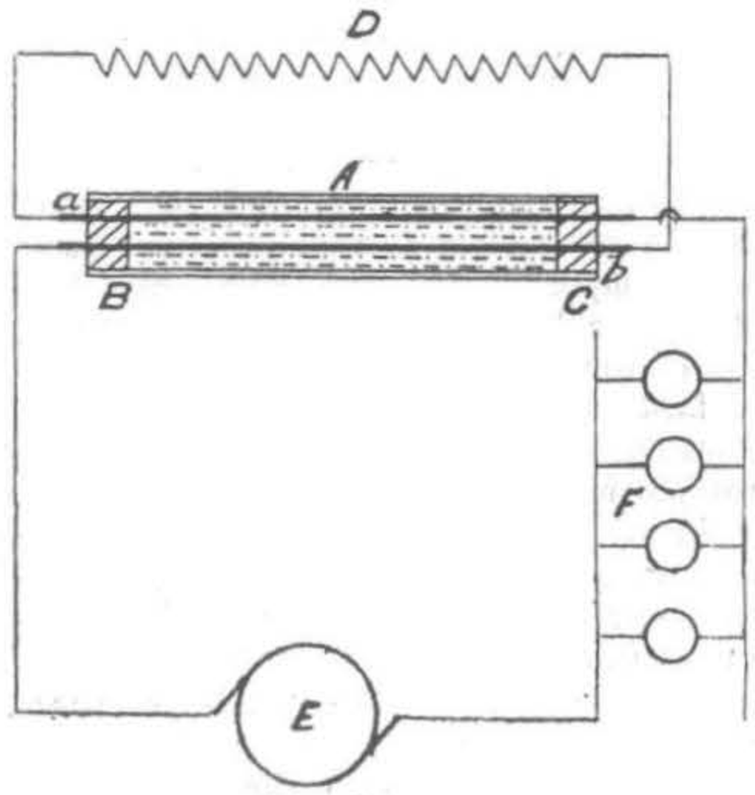

FIG. 1.

The first item consists of an electrolytic meter, the principle underlying the action of which is as follows: A conductor is immersed in a metallic solution, and the current to be measured is passed through it. The action of the current in passing is to remove from or deposit on the conductor a certain quantity of metal, and by so doing alter the electrical resistance of the conductor, which can thus, if necessary, be caused to register automatically when the current passing rises above or falls below certain limits. Fig. 1 is a diagrammatic view of the apparatus. A is the glass containing tube of cylindrical form, sealed at each end by an insulating and watertight plug, B C, through which pass the leading-in wires; *a b* are the active conductors of the apparatus. They are placed parallel to one another throughout the length of the tube, A, and are connected in series through a resistance, D, with the generator, E, and energy-consuming circuits, F, in such a manner that there is an equal difference of potential between them throughout their whole length.

Under the conditions described above a current passing through *a* and *b* will establish a difference of potential between them proportional to the current strength. This gives rise to a leakage between them which is proportional to the potential difference, and therefore to the strength of the current passing through the conductors. Again, owing to the fact that there is a constant difference of potential between the two conductors throughout their entire length, the current density through the electrolyte will also be uniform, and as a natural consequence the metal will be removed at a uniform rate from one conductor and deposited at an equal rate on the opposite one, thus causing an alteration in their electrical resistances proportional to the strength of the current passing through them, from which given quantity the value of the latter can be readily ascertained—in the first instance by experiment, and in the second by comparison. It will be seen that this apparatus is somewhat similar in principle to that of Edison, with this difference—that the results depend in one case on electrical resistance, and in the other on actual weight.

The *modus operandi* of the apparatus is as follows: The two conductors, *a* and *b*, are first accurately gauged and measured for resistance, the results being carefully noted. A fixed current is then passed through the instrument for a certain time, and the respective diminution and increase in the resistance of *a* and *b* is then ascertained. From the facts thus gathered a constant is obtained whereby the instrument is rendered capable of accurately recording any succeeding currents which may traverse the active conductors, *a* and *b*. A test of its accuracy is provided by the separate measurement of the two conductors, when the gain in the resistance of one should equal the simultaneous loss in the other, or, as a further proof, the resistance of the two conductors measured in series with the resistance, D, should be a constant quantity. It is hardly necessary to mention that at certain intervals the direction of the current in the two conductors, *a* and *b*, must be reversed in order to equalise the metallic reduction and deposition respectively. The advantages appertaining to this form of meter are obvious: The readings can be made directly by means of an ohmmeter; the whole of the current may be passed through it provided that the gauge of the two wires, *a* and *b*, be sufficiently large, thus rendering the use of shunts and attendant inaccuracies unnecessary. The accuracy of the instrument is not impaired to any appreciable extent by temperature variations. Above all, it is a cheap form of apparatus for the purpose.

The next inventions with which I purpose dealing are

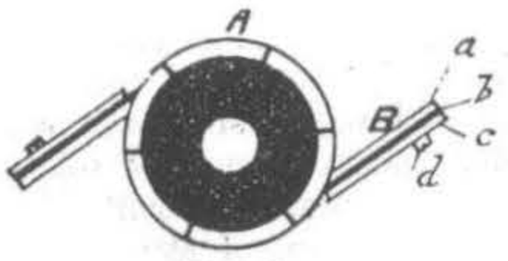

FIG. 2.

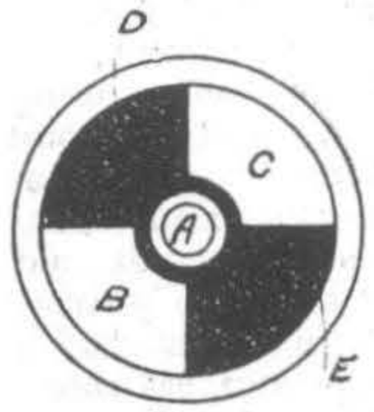

FIG. 3.

those involved in the manufacture of dynamo commutators and brushes, in which sparking is reduced to a minimum or even rendered impossible. Devices for the reduction of this generally necessary evil were no doubt suggested to Mr. Tesla by his marked antipathy to commutators of any description, brought to light by a consideration of his commutatorless motors. Fig. 2, which is a diagram of an anti-sparking brush device designed by him, will help to explain its principle. A is the end view of an ordinary continuous-current dynamo commutator, B being the brush, which is divided into three principal parts: *a*, the metallic brush, as usual; *b*, a plate of mica or other suitable insulating material, such as asbestos paper; and *c*, a flexible spring, which regulates the pressure of *b*, and is governed by the set screw, *d*. The principle of the device will no doubt be understood from its construction. The formation of an arc or spark between the brush, *a*, and the commutator segment which is just leaving it is prevented by the contact made between the insulating strip, *b*, and the corresponding insulating material of the commutator. In some forms of this brush two separate strips of insulating material have been introduced at *b*, instead of one, with advantage.

In another device designed with the same object in

view—viz., the elimination of sparking between commutator segments and collectors—both apparatus take the form of discs with their faces well surfaced revolving accurately against one another. Fig. 3 is a diagrammatic end view of the commutator disc of one of these devices. A is the dynamo shaft; B and C are the metallic sectors; D and E the corresponding sectors of insulating material, this being only a simple two-part commutator. The whole surface of the disc in Fig. 3 is accurately faced and smoothed, so that both metallic and insulating sectors are flush with one another. The collector disc is the facsimile of that shown in Fig. 3, but is not keyed to the shaft of the dynamo.

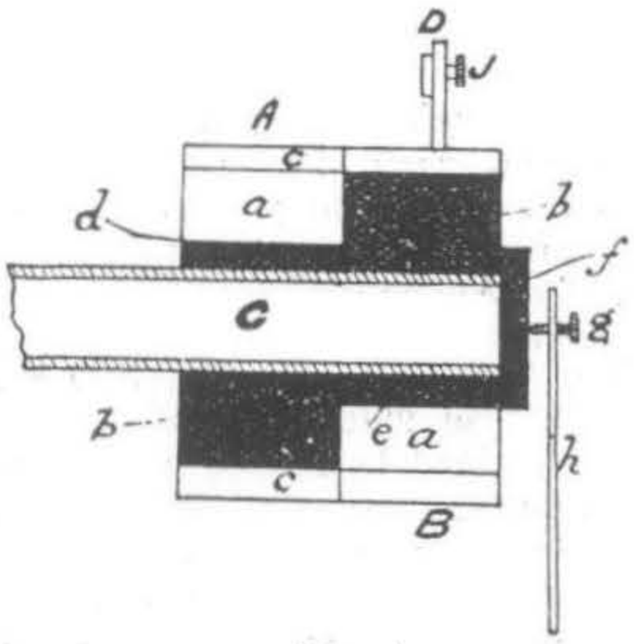

FIG. 4.

A general idea of the complete apparatus may be gained by a study of Fig. 4, which represents a longitudinal section of the commutator, A, and B, the collector; *a a* represent two metallic and *b b* two insulating sectors; *c c* are insulating rings which surround the outside edges of the sectors, and prevent a dissolution of partnership on the ground of centrifugal force; C is the dynamo shaft, through the tubular extremity of which are brought the wires from the armature coils; *d* is an insulating collar placed between the sectors and the shaft to prevent contact, and revolving with the latter; *e* is a similar insulating sleeve for the collector, and the dynamo shaft revolves inside it; a cap, *f*, is screwed on the end of this movable sleeve, and the pressure of a set screw, *g*, on the end of a stiff steel spring, *h*, serves to maintain good surface contact, between the commutator and collector surfaces; D is a quadrant for adjustment with a set screw, *j*, which takes the place of the ordinary brush-rocker, and serves to set the angle of the collectors. The advantages of this form of dynamo commutation will also be readily seen. The short-circuiting interval is reduced to a minimum by the simultaneous "make" and "break" of the sectors, which reduces sparking, besides increasing the efficiency of the machine.

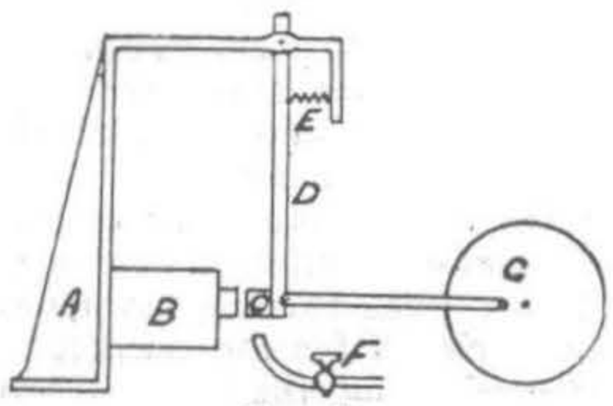

FIG. 5.

In another form of the same device a liquid—mercury, to wit—takes the place of the solid metallic sectors. The two discs are built completely of insulating material in this case, and in place of the solid metallic sectors cavities are left in their faces. The terminals of the collector end in airtight spring plungers or buffers, which serve to regulate the pressure of the mercury under the action of centrifugal force, and also to ensure a good contact between it and the terminal screws. In both forms the insulating blocks should be constructed of some durable material, such as glass or marble, whilst in the solid form the efficiency and durability may be augmented by facing the edges of the metal segments, between which the major portion of the sparking would tend to take place with some durable conducting material, such as platinum.

In the course of his electrical research, Tesla has not failed to study the subject of thermomagnetism, and as a result he constructed one or two rather ingenious forms of thermomagnetic motor, which are, however, for obvious reasons, still in an experimental stage. They are founded on the fact proved by Dr. William Gilbert at the beginning of the seventeenth century, that a magnet or lodestone when heated to redness is deprived of its magnetism. The principle underlying the device is illustrated in Fig. 5, in which A is a standard or support carrying a magnet, B, permanent or otherwise. C is an armature of the latter, forming the bob of a pendulum rod, D, supported above; E is a spiral spring which comes into play when the armature is demagnetised; F is a gas-burner or other suitable source of heat; and G is a wheel and connecting rod by which the power is converted into the ordinary form of rotary motion. Its action is as follows: The armature, C, is in the first instance attracted by the magnet against the tension of the spring, E. On heating C by means of the burner, F, it loses its magnetism and is drawn back by the spring out of the flame. On cooling, the magnetism again comes into play, and the armature returns to its original position, to be again heated, and so it goes on, the motion being of necessity somewhat slow.

There are several modifications of this motor, all working on the same main principle. In one the core of the electromagnet is made movable, and takes the place of the swinging armature, C, which is fixed. To the end of the magnet core it attached a shield, which, when the armature loses its magnetism and the core is drawn back by the spring in consequence, comes between the armature and the flame, and allows the former to cool by intercepting the heat rays. In another form the armature rocks over the two pole-faces of a permanent horseshoe magnet spanned by a sheet-iron keeper, which latter is heated by a burner whose tap valve is controlled by the rocking armature itself.

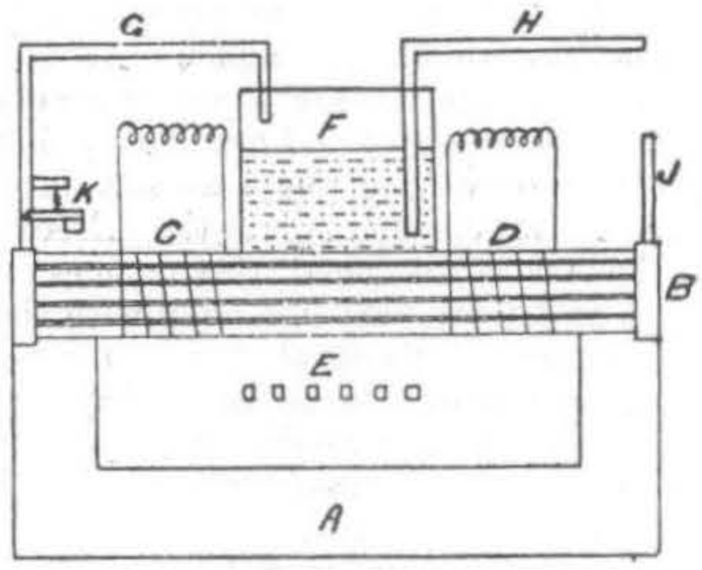

FIG. 6.

A study of the reverse of these conditions also led Mr. Tesla to construct a pyro-magnetic generator based on the undermentioned laws: "Electricity, or electrical energy, is developed in any conducting body by subjecting such body to a varying magnetic influence. The magnetic properties of iron or other magnetic material may be partially or entirely destroyed or caused to disappear by raising it to a certain temperature, but restored and caused to reappear by again lowering its temperature to a certain degree." Tesla's apparatus for practically applying these laws is represented diagrammatically in Fig. 6. A is a permanent magnet, the poles of which are bridged across by a casing containing a number of iron tubes, B. Round this compound bridging-piece are wound the collecting coils, C and D, which serve to collect the current generated. E is a closed furnace surrounding the central portion of the bridging-piece, and surmounted by a boiler, F, the steam generated in which is conveyed to the tubes, B, in the bridging-piece by the pipe, G. H is the water-supply pipe, and J the exhaust. The admission of steam is regulated by a valve, K, under the control of the magnet, A.

From the several inventions dealt with above, it will be seen that Mr. Tesla has not confined his labours solely to the field of high frequencies.

Tesla Apparatus Tried on Tuberculosis.

Although technical information has not been given out concerning it, the report is that Tesla oscillators, or something of the kind, are being tried by Dr. Croft C. Carroll of 21 East Twenty-fourth street, New York, and the result on two notably bad cases of tuberculosis is said to have been remarkably beneficial. Dr. Carroll is using the apparatus in his public clinic. Dr. John B. Rich, president of the American Microscopical society, is quoted as declaring it the most wonderful demonstration of positive beneficial results that he had ever seen in the treatment of germ diseases. One of the most notable cases cured was that of Dr. E. P. Iliff of Newark, N. J., a specialist in lung diseases, who contracted tuberculosis from one of his patients. He was given up for lost by his brother physicians, and in ten days after being treated was out attending to his practice. Rev. S. W. Switzer, of the Baptist tabernacle, Harrison, N. J., was very low with consumption, but was so helped that he was back on duty in less than three weeks. The principle of the apparatus is said to be the driving through the affected parts of a sufficient quantity of electricity to kill the germs, which are then eliminated from the system by nature.

NIAGARA'S POWER FOR CITY WHEELS

Only One Result of the Plan Which Nikola Tesla Holds Will Revolutionize Industries.

ELECTRICITY TO BE CARRIED IN ICE

Inventor Declares That It Can Be Transmitted Across Continent Without Loss.

AMAZING IN SIMPLICITY

After Seven Years of Work and Experiment the Idea Came Upon Student Like a Flash.

Methods of transmitting electrical currents will be revolutionized if the results anticipated by Nikola Tesla from his most recent invention for the insulation of wires meet with the success in practice indicated by his experiments. There will then be no danger of deaths or injury by contact with live wires. It will be possible to transmit a current of high voltage hundreds of miles with no appreciable loss.

By cheapening the cost of electricity at the place where it is to be used all industries dependent upon electricity for their motive power may be carried on at a vastly less expense. These results will be accomplished by using an insulation of ice or other frozen material.

Mr. Tesla was informed yesterday that his application for a patent covering this ground had been granted.

When I saw him, last night, at the Waldorf-Astoria, Mr. Tesla said that he was greatly pleased with the outcome of the experiments, upon which he had been working for seven years.

Amazed by Its Simplicity.

"Professor Dewar, of the Royal Institute, gave me the suggestion," said he, "which set me thinking along this line. That was in 1893. Realizing the great practical value of such an invention, I thought much about the subject, until a few weeks ago, when the complete system by which the desired end might be attained suddenly flashed across my mind as I was pondering upon the problem in my laboratory. Then the simplicity of the plan amazed me.

"Let me describe this method of insulation to you in its most comprehensive form. All wires will, of course, be placed under ground before my cold air insulation can be used.

"Imagine, now, a great trough extending, if you wish, across the continent. It must contain a quantity of water or some other substance which will freeze. From my experiments I judge that sawdust and water will prove most effective. For the purpose of transmitting the current long distances I shall use a thin metal tube, capable of resisting three hundred pounds' pressure to the square inch. This tube will be submerged in the substance which I intend to freeze.

Most Interesting Feature.

"In the whole discovery the most interesting feature is the method I have devised for freezing the material in the trough. Five or six feet below the surface the ground itself is very cold. Here the trough would be buried. Through the tube there will then be forced a current of gas—probably hydrogen—reduced to a temperature of minus 200 degrees or thereabouts.

"This, under ordinary circumstances, will be sufficient to freeze the material surrounding the tube in the trough, and also to neutralize the heat which would be generated by the electricity.

"It has been known since the days of Faraday that an electrical current cannot break through an insulation of ice. My success lies in discovering how to practically apply this truth. To show of what gigantic worth it may be needs but a moment. Grant that the invention has, as I believe, given to the world an almost perfect insulator, immediately there follow results which will directly or indirectly affect every manufacturing industry which in any way uses electricity.

No Loss in Transmission.

"This will follow from the fact that no electricity will be lost in transmission. The cost of the new insulation will in the end be cheaper than that now used, and so it follows that the electricity which is to be utilized in a thousand different ways can be produced at a less cost. To telephone and telegraph companies, therefore, you see that my invention will be indispensable.

"Water power converted into electricity can by the new method of insulation be carried thousands of miles. At present the loss of electricity due to unsatisfactory insulation makes this impossible. I have been considering the possibility of carrying the power of Niagara to this city, and find that it can be done with a loss of not more than one-half per cent to one per cent.

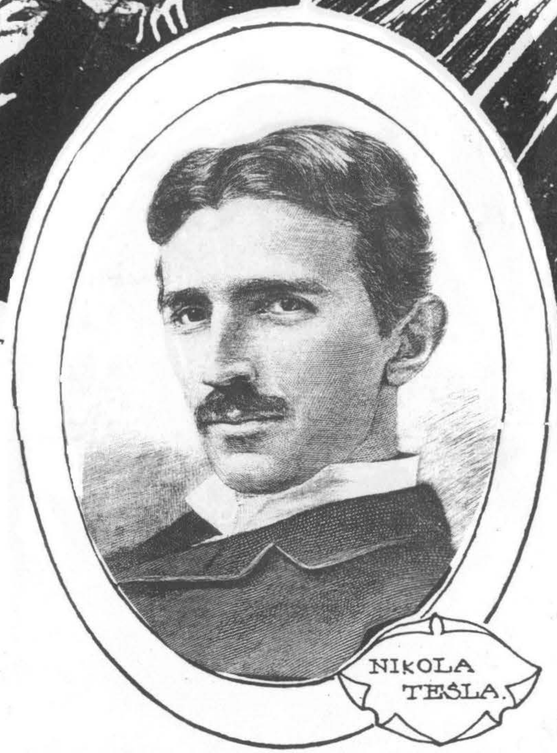
"For the first time in history a power will be used for insulation instead of a property. Deaths from contact with exposed wires will be prevented by the new method. The increase in the speed of exchange of telephone and telegraph messages will be pronounced after the adoption of my discovery.

"These are the important changes in the electrical world which will be wrought by this invention. There will be also innumerable indirect results."

Mr. Tesla said that he hoped to apply his new discovery to electric surface railways. He said that he was working upon a plan by which the cars could be propelled without direct contact with the wire. This plan is still in an embryotic condition, and for this reason Mr. Tesla declined to discuss it in detail.

500,000 VOLTS OF ELECTRICITY PASSED THROUGH THE BODY TO CURE CONSUMPTION---TESLA'S IDEA.

800 Volts Ordinarily a Fatal Current, but by the Marvellous Oscillator Which the Electrician Has Devised the Vaster Current May Be Made as Harmless as Sunlight.



APPLYING THE TESLA ELECTRODE OVER THE HEART--FEATURE OF THE TREATMENT TO CURE CONSUMPTION.

APPLYING THE TESLA ELECTRODE ON SIDE OF FACE TO CURE NEURALGIA.

APPLYING THE TESLA ELECTRODE TO BACK OF NECK TO CURE SPINAL MININGITES.

NIKOLA TESLA has recently invented an electrical instrument which he thinks will revolutionize the science of medicine. By means of an oscillator he proposes to cure consumption, cancer and other forms of disease which have hitherto resisted all the efforts of medical science.

Ordinarily, 800 volts of electricity passed through the body of a man by means of the dry-cell method are sufficient to kill him.

By Tesla's machine half a million volts can be administered to a patient without ill effect. One scarcely feels the subtle fluid, which, in another form, would instantly annihilate him.

A peculiar property claimed for the Tesla electricity is that it affects the germs of the disease without destroying the cells of the tissues of the body. Many doctors could cure consumption if they had only the disease bacillus to deal with. But they have to consider the cell structure of the human body. A germicide powerful enough to kill the consumption germ would also destroy the tissues in which this germ is conducting its operations. Ordinary electricity passed through the tissue would reduce it to its elemental state.

The Tesla oscillator is now in use by New York physicians, who record marvellous results. Patients suffering from chronic consumption have been cured permanently. Men whose hours have been numbered have taken up their beds and walked.

The Tesla oscillator not only cures consumption. Its effect in fevers has been pronounced marvellous. In four seconds the temperature has been brought down from 105 degrees to normal—98 2-5. The pulse, racing at fatal speed, has been checked and made to beat time to perfect health. The breath, short and gasping, has been sustained, and all pain from the lungs has been eliminated.

Should Tesla's new discovery prove all that the inventor claims for it, physic may be thrown to the dogs. A few days of Tesla's treatment, painless and pleasant, will suffice.

BY NIKOLA TESLA.

My new oscillator is based on a principle which I discovered some time ago. It involves the use of vibrations of an electrical condenser which stores electrical energy. This energy is of an explosive nature, like the power locked up in dynamite, only it is many times more powerful.

When this energy is suddenly released, as in my machine, it produces quickly varying oscillations which are able to penetrate through bodies. Though this energy may be enormous in amount, it is not harmful in nature.

By means of this machine I may pass at least half a million volts of electricity through a man without injury. Indeed, it may be utilized with beneficial effect.

I am of opinion that electricity in this form may be used as a means of stamping out internal disease. When you stand in the sunlight your body is receiving millions of volts of electricity; and yet, this is not of a harmful kind. It is the same way with my new electric energy. If you hold up your hand in the light you will see that certain portions of it are illuminated. The rays have passed into the flesh. Sunlight, as is well known, helps to cure many diseases.

The germs of consumption and kindred diseases grow in darkness. Almost all organic growths develop under the absence of sunlight and electrical energy. Now, if these portions of the body in which germs are growing are subjected to electricity the diseases will be unable to live in the changed atmosphere, as it were, and the disease will disappear. This has long been recognized in medical science; but electricity could not be administered in sufficiently powerful quantities to affect germs without hurting the tissues themselves.

My oscillator enables this to be done. That is why I base such hopes on its career as a therapeutic agent. It has already been tried and remarkable results have been obtained.

Tesla's oscillator is a small, drum-like object, oblong in form. It is about two feet long by one foot wide. It is connected with the ordinary street wires, setting up its wonderful oscillatory electricity as soon as the current is turned on.

The current is applied to the patient by means of a glass electrode which is spoon-shaped. The patient feels no sensation whatever, and would be unconscious of the treatment were it not indicated by a redness about the part to which the current is applied. When the patient is undergoing treatment and the oscillator is working in full force sparks may be obtained from any portion of the body.

We are now in the midst of what is sometimes called the "silly season" in the newspaper world. It is a long time, however, since we have seen anything more egregiously silly than the announcement in the *Daily Mail* of last Saturday as to an alleged new discovery by Nikola Tesla. We do not know what proportion of the startling announcements frequently made in connection with the name of this electrician is authorised by him, but we hope that for his sake it is a very small one. In the present instance Tesla is reported to have discovered a method of perfectly insulating an electrical conductor by surrounding it with a frozen mixture of water and sawdust in a thin metal tube. This amazing insulator, Tesla is reported to declare, renders possible the transmission of electric power from New York to London. A short while ago Tesla's schemes were in the ether above the earth's atmosphere. Now they appear to be at the bottom of the Atlantic ocean. We wonder where they will turn up next.

Tesla's Latest Scheme.

As noted in this week's patent record of the Western Electrician, a patent has been granted to Nikola Tesla on the method of insulating conductors which consists in freezing water or other mixture by artificial means around the conductor to be insulated and maintaining the insulator in its frozen condition. Much has been said about the revolutionizing character of the invention by the daily press. Just how the system which requires the maintenance of a set of refrigerating plants along a transmission line is to be superior to present systems is not pointed out.

ELECTRICITY UP TO DATE—AND BEYOND.

Fearful and wonderful as are many of the attributes of electricity to the man in the street, the *ultima Thule* has now been reached, according to our esteemed contemporary the *Daily Mail*.

"TESLA'S LATEST MARVEL.—Transmitting Electricity without Loss,"

form the headlines of an article which begins with the words—"Niagara Falls to light the streets of London, and cook the dinners of its 5 million inhabitants," and ends with the brutally practical consideration that "the cost of the insulation is the only factor to be considered." How electricity is to be transmitted without loss is explained with that airy indifference to such trifling obstacles as physical impossibilities that is characteristic of the efforts of the lay press when dealing with technical questions. In the early days of electric lighting it used to be said that most electrical engineers could lawfully claim descent from Ananias and Sapphira, but even the expert witness might be expected to develop a conscience if called upon to substantiate some of the means suggested by the *Daily Mail* by which electricity is to be transmitted without loss. For instance, the following gems of thought are worth quoting:—

"The chief difficulty to be faced in the long-distance transmission of electricity is the power lost in the line by reason of its resistance, which fritters the current down to heat." Apparently the E.M.F. is spared this indignity.

But how wonderful is the intelligence which, in the description of a difficulty, contrives to imply the way of escape! Of course, we can see with half an eye from this delphic utterance, that all that has to be done is to eliminate the resistance, and the difficulty will vanish. Then the master mind that prompted the article, in a few pithy sentences, shows how simply this may be done.

"A trough will extend across the entire continent of America, or across the Atlantic. In the trough will be placed sawdust and water." [It may reasonably be assumed that the act of "placing" the water when crossing the bottom of the Atlantic will be a work of supererogation.]

"A thin metal tube, capable of resisting a pressure of 300 lbs. to the square inch, will be used for the purpose of transmitting the current to long distances." [Note, only *one* tube—so simple.]

"The trough is to be buried 5 or 6 feet below the surface." [Presumably below the surface of the bottom of the Atlantic; but "buried" is a horribly suggestive word.]

"A current of gas, probably hydrogen, will be forced through a pipe submerged in the substance to be frozen,

The hydrogen will be reduced to — 200° C., which will suffice to freeze the material, and *neutralise the heat generated by the passage of the electricity*."

The italics are ours. Why is any heat generated? Transmission without loss means conductors without resistance, hence absence of heat. But if heat be generated, the neutralisation comes a day after the fair, as far as any saving is concerned. It would be better, if we might hazard a suggestion, to neutralise the resistance.

Nothing is said about the cost of producing the "gas at — 200° C.," or the quantity that will be required, nor is the somewhat delicate subject touched upon of labour troubles which might ensue if workmen were asked to break up and make good the bottom of the Atlantic under a pressure of anything from 2 tons per square inch upwards. What would the fish say to a cold streak at the bottom of their home? They might strike, and be joined by horses and birds out of sympathy. The possible prospect of fish refusing to be caught, horses refusing to move, and birds declining to fly, ought surely to awaken some sense of responsibility in Mr. Tesla's breast!

But we have not exhausted the possibilities of this system. Mr. Tesla is stated to believe that his new system of insulation is "indispensable to telephone and telegraph companies." The inclusion of each telephone wire in a trough filled with sawdust and water, and reduced to — 200° C., opens up some pleasing prospects on the overhead system.

Mr. Tesla is stated to believe, further, that no electricity will be wasted in transmission, and that "water-power converted into electricity will be carried thousands of miles." Query, in a trough?

The *Daily Mail*, in concluding, points out that, "by Mr. Tesla's invention, there is now practically no limit to the distance to which electricity may be conveyed."

The *Daily Mail* has spoken. We have, therefore, reached finality, and we may imagine interplanetary space mapped out, in the near future, into districts by troughs of sawdust and water at — 200° C., and agencies appointed in each of the more important planets for the supply of electricity on sale or return. Why not? it would be just as easy as to "trough" the bottom of the Atlantic.

THE SLABY-ARCO SYSTEM OF WIRELESS TELEGRAPHY.

The Slaby-Arco system, as described in a pamphlet issued by the General Electric Company of Berlin, though based on essentially the same principles as the Marconi system, differs

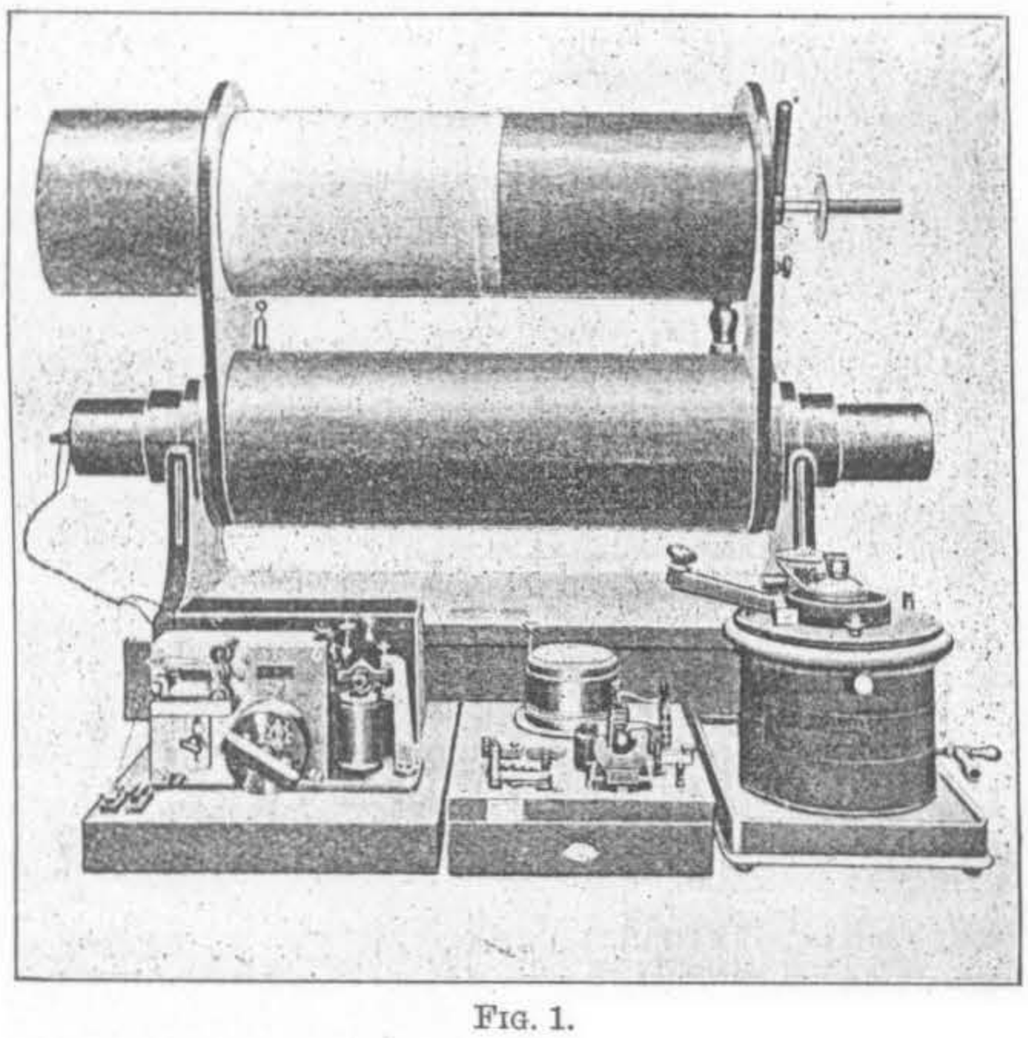


Fig. 1.

from the latter in some important respects. The vertical wire, for example, which is insulated in the Marconi arrangement, is in the Slaby-Arco system connected with earth for both transmitting and receiving.

The connections of the transmitting apparatus are shown in diagram 1. A condenser, C, is charged with high tension

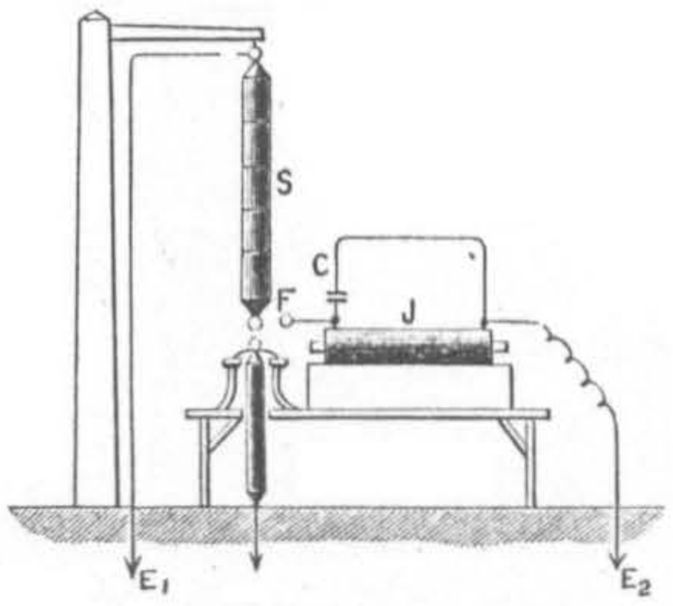

Diagram 1.

electricity by the induction coil, J, and discharges itself on one side through the spark-gap, F, and the transmitting wire, and on the other side through E_2 direct to earth. According to the inventors the technical advantages of this arrangement are very decided, for as only one of the condenser plates and one knob of the radiator—parts which can be permanently insulated, and from which danger to the operators can be completely prevented—are at a high potential relative to the earth, difficulties of insulating the transmitting wire are obviated; and even on taking hold of the wire scarcely perceptible shocks are felt.

For the production of the high potential the inventors ordinarily use a 40 or 50 cm. induction coil with a mercury turbine contact breaker; the coil may be directly connected with an electric light circuit thus dispensing with accumulators or dry cells. The use of a special Morse key is rendered unnecessary by a suitable appliance fitted to the turbine contact breaker. If an alternating current is available the arrangement becomes still simpler and more convenient, since in that case the contact breaker can be wholly dispensed with, and the induction coil can be directly connected with the alternating current circuit. The condensers used are made of "micanite," and are mounted on the induction coil itself, this being done in such a way that the high tension pole of the induction coil and of the condenser is protected from contact. (See fig. 1.)

The arrangement of the receiving apparatus is shown in diagram 2. In this figure S is the aerial wire netting, F the coherer, R the relay of the Morse instrument, and B the battery.

The action of the receiver is such that, when the initial high resistance of the coherer has been reduced by the etheric waves, the battery, B, is enabled to send a current through the relay, the aerial wire, and earth.

It is a characteristic feature of the receiving apparatus that the pulsating magnetic field produced by the transmitter may be received not only on a simple aerial wire, but also on an earthed wire cage or netting, whereas in previous arrangements the waves which reached the coherer, F, were shunted by the local circuit, and their effect was thereby weakened; in the Slaby-Arco system the series arrangement adopted completely removes this defect; atmospheric disturbances are also greatly diminished by the series arrangement.

Another improvement in the receiver consists in the introduction of an automatic interruption of the coherer circuit. Matters are so arranged that the blow of the tapper is only given to the coherer tube after the tension of the coherer elements is taken off. By this means not only is easy and satisfactory decoherence effected, but the life of the coherer is said to be considerably prolonged, since the sparks on breaking circuit, which would otherwise occur in the interior and would gradually destroy the coherer powder, are caused to take place externally.

A further improvement is claimed in the construction of the coherer, a variation in the sensitiveness of which is rendered possible by means of hermetically sealed leads. The

coherers are all tested for long distances, but each receiver for movable stations is furnished with an appliance for diminishing the intensity, so that the apparatus, in spite of its great sensitiveness, will work perfectly even at very short distances.

It is claimed that the system is particularly useful for communications between ships at sea or ships and the coast,

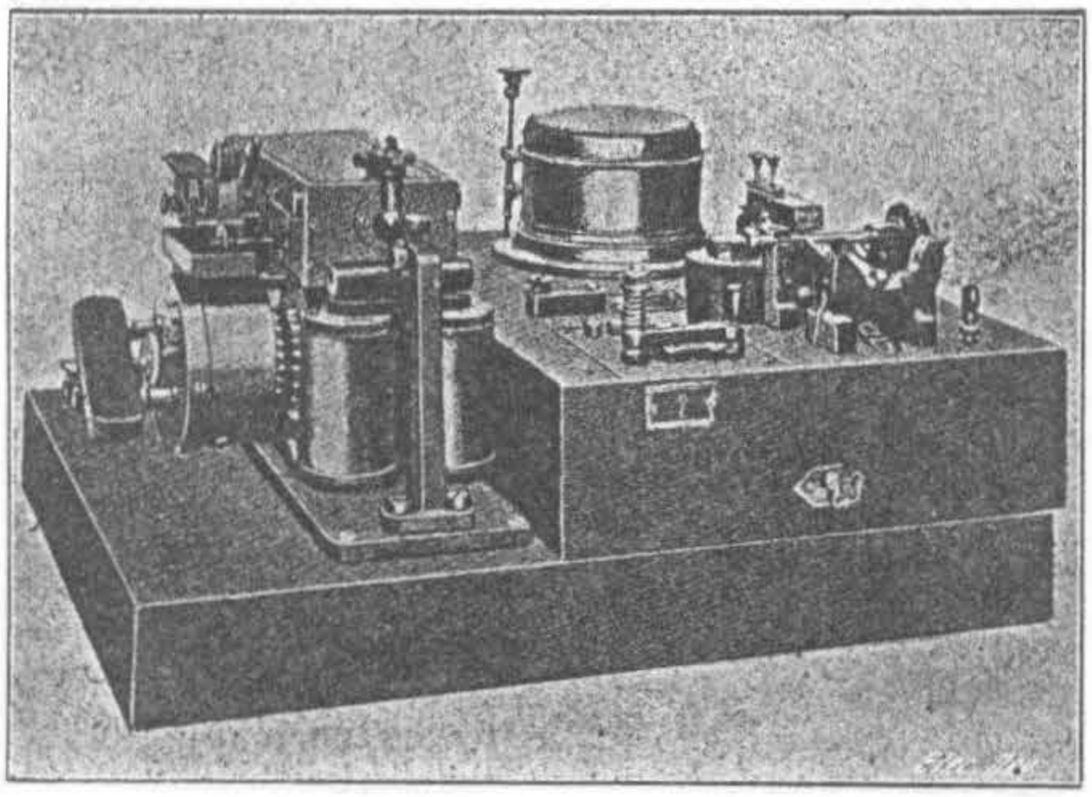

Fig. 2.—Receiving Apparatus.

and that experiments carried out by the German Navy prove that for such purposes the system is perfectly reliable.

At present the radiating power and sensitiveness of the apparatus is such that signals can be *safely* transmitted to distances of 25 to 28 miles over sea with vertical wires 38 to 44 yards high.

On land the General Electric Company maintain communication between their cable factory at Oberschöneweide and their central office in Berlin, a distance of 9⅓ miles. The vertical wires, about 55 yards high, are supported by two tall chimneys.

The advantages of the Slaby-Arco system, as compared with other systems, consists, it is stated, not so much in its

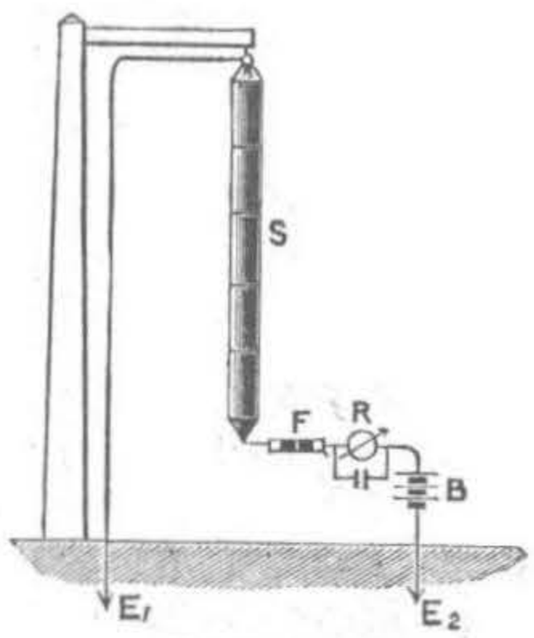

Diagram 2.

superiority in respect of the distances, as in its practical serviceability, prevention of danger from high pressures, avoidance of difficulties of insulation in the transmitter, and of atmospheric disturbances in the receiver, together with a greater solidity and simpler manipulation of the whole receiving apparatus. It is for these qualities that the system has been adopted by the German Navy.

TESLA ROTATING FIELD PATENTS SUSTAINED.

Judge Townsend, of the United States Circuit Court for the District of Connecticut, rendered a decision on August 29th sustaining the Westinghouse Electric and Manufacturing Company in its suit against the New England Granite Company for alleged infringement of the Tesla polyphase patents Nos. 381,968, 382,279 and 382,280, granted in 1888.

These are the fundamental Tesla polyphase patents, and in granting the injunction prayed for the court orders an accounting as to all the claims in suit. A synopsis of the argument of the case can be found in the *Electrical World and Engineer*, Vol. XXXIV, page 782, Nov. 18, 1899.

*See *Electrical Review* (N. Y.), Vol. XXXVII, No. 12, page 277.

Tesla.—WRIGHT.—An illustrated article on "Some Novel Inventions of Nicola Tesla." He describes an electrolytic meter, several anti-sparking brush devices, and models of a thermomagnetic motor and of a pyro-magnetic generator.—*Lond. Elec. Eng.*, Aug. 10.

TESLA'S ELECTRICAL METHOD OF CURING CONSUMPTION.

FROM an American paper we learn that "Tesla's Idea" for curing consumption is to pass 500,000 "volts of electricity" through the body. Thus we read :—Nikola Tesla has recently invented an electrical instrument which he thinks will revolutionise the science of medicine. By means of an oscillator he proposes to cure consumption, cancer, and other forms of disease which have hitherto resisted all the efforts of medical science. Ordinarily, 800 volts of electricity passed through the body of a man by means of the dry-cell method are sufficient to kill him. By Tesla's machine half a million volts can be administered to a patient without ill effect. One scarcely feels the subtle fluid, which, in another form, would instantly annihilate him. A peculiar property claimed for the Tesla electricity is that it affects the germs of the disease without destroying the cells of the tissues of the body. Many doctors could cure consumption if they had only the disease bacillus to deal with. But they have to consider the cell structure of the human body. A germicide powerful enough to kill the consumption germ would also destroy the tissues in which this germ is conducting its operations. Ordinary electricity passed through the tissue would reduce it to its elemental state.

The Tesla oscillator is now in use by New York physicians, who record marvellous results. Patients suffering from chronic consumption have been cured permanently. Men whose hours have been numbered have taken up their beds and walked. The Tesla oscillator not only cures consumption. Its effect in fevers has been pronounced marvellous. In four seconds the temperature has been brought down from 105° to normal—98⅔°. The pulse, racing at fatal speed, has been checked, and made to beat time to perfect health. The breath, short and gasping, has been sustained, and all pain from the lungs has been eliminated. Should Tesla's new discovery prove all that the inventor claims for it, physic may be thrown to the dogs. A few days of Tesla's treatment, painless and pleasant, will suffice.

The following is given as from Tesla himself: "My new oscillator is based on a principle which I discovered some time ago. It involves the use of vibrations of an electrical condenser which stores electrical energy. This energy is of an explosive nature, like the power locked up in dynamite, only it is many times more powerful. When this energy is suddenly released, as in my machine, it produces quickly varying oscillations which are able to penetrate through bodies. Though this energy may be enormous in amount, it is not harmful in nature. By means of this machine I may pass at least half a million volts of electricity through a man without injury. Indeed, it may be utilised with beneficial effect. I am of opinion that electricity in this form may be used as a means of stamping out internal disease. When you stand in the sunlight your body is receiving millions of volts of electricity; and yet, this is not of a harmful kind. It is the same way with my new electric energy. If you hold up your hand in the light you will see that certain portions of it are illuminated. The rays have passed into the flesh. Sunlight, as is well known, helps to cure many diseases.

The germs of consumption and kindred diseases grow in darkness. Almost all organic growths develop under the absence of sunlight and electrical energy. Now, if these portions of the body in which germs are growing are subjected to electricity, the diseases will be unable to live in the changed atmosphere, as it were, and the disease will disappear. This has long been recognised in medical science; but electricity could not be administered in sufficiently powerful quantities to affect germs without hurting the tissues themselves.

My oscillator enables this to be done. That is why I base such hopes on its career as a therapeutic agent. It has already been tried, and remarkable results have been obtained.

The description given is as follows :—Tesla's oscillator is a small, drum-like object, oblong in form. It is about 2ft. long by 1ft. wide. It is connected with the ordinary street wires, setting up its wonderful oscillatory electricity as soon as the current is turned on. The current is applied to the patient by means of a glass electrode which is spoon-shaped. The patient feels no sensation whatever, and would be unconscious of the treatment were it not indicated by a redness about the part to which the current is applied. When the patient is undergoing treatment, and the oscillator is work-in full force, sparks may be obtained from any portion of the body.

The comment is that possibly Tesla has never said anything to warrant these statements.

THE TESLA DECISION.

Elsewhere in this issue will be found a very full abstract of the Townsend decision, mentioned by us last week, in favor of the Tesla rotating magnetic field patents which have been in suit for some few years past. It will be seen that the judge treated as insufficient anticipations the work of Baily, Siemens, Deprez and Bradley, all of which had been relied upon and much of which was admittedly of a prophetic character, to say the least. The judge took occasion to compliment Mr. Tesla on the high value of his work to the art, in view of the enormous extension given to the transmission of power by such methods since the distinguished inventor read his memorable paper before the American Institute of Electrical Engineers.

General News.

Decision in Favor of the Tesla Rotating Magnetic Field Patents.

As announced in these pages last week, Judge Townsend in the U. S. Circuit Court for the District of Connecticut has handed down a decision sustaining three broad Tesla patents—Nos. 381,968, 382,279 and 382,280—of May 1, 1888, in the suit of the Westinghouse Electric & Manufacturing Company against the New England Granite Company, which had been using a Cushman phase motor operated from a General Electric three-phase generator. The case was reviewed at considerable length in the ELECTRICAL WORLD AND ENGINEER of Nov. 18, 1899, when the chief points in contention were brought out. The full text of the decision has now been handed down, which follows closely the lines then noted.

The claims in issue in patent No. 381,968 are as follows:

"1. The combination, with a motor containing separate or independent circuits on the armature or field-magnet, or both, of an alternating-current generator containing induced circuits connected independently to corresponding circuits in the motor, whereby a rotation of the generator produces a progressive shifting of the poles of the motor, as herein described.

"3. The combination, with a motor having an annular or ring-shaped field-magnet and a cylindrical or equivalent armature, and independent coils on the field-magnet or armature, or both, of an alternating current generator having correspondingly independent coils, and circuits including the generator-coils and corresponding motor-coils in such manner that the rotation of the generator causes a progressive shifting of the poles of the motor in the manner set forth."

That of patent No. 382,280 is as follows:

"1. The method herein described of electrically transmitting power, which consists in producing a continuously progressive shifting of the polarities of either or both elements (the armature or field-magnets or magnets) of a motor by developing alternating currents in independent circuits, including the magnetizing coils of either or both elements, as herein set forth."

The claims in issue of patent No. 382,279 are as follows:

"1. The combination, with a motor containing independent inducing or energizing circuits and closed induced circuits, of an alternating-current generator having induced or generating circuits corresponding to and connected with the energizing circuits of the motor, as set forth.

"2. An electro-magnetic motor having its field magnets wound with independent coils and its armature with independent closed coils, in combination with a source of alternating currents connected to the field coils and capable of progressively shifting the poles of the field magnet, as set forth.

"3. A motor constructed with an annular field magnet wound with independent coils and a cylindrical or disk armature wound with closed coils, in combination with a source of alternating currents connected with the field-magnet coils and acting to progressively shift or rotate the poles of the field, as herein set forth."

The complainant's theory of the invention was that the gist of it was the utilization of the alternating currents generated by an alternating-current dynamo or generator for effecting such shifting of the magnetic poles or resultant attractive forces upon the armature of a motor, and thus causing such armature to rotate in response thereto. His broad invention was the production in a motor of a progressively shifting magnetic field (or pole) by means of two or more independent alternating currents, differing in phase, and circuits which preserve the independent character and phase relation of such currents."

By way of defence, the decision goes on, the defendants relied upon four prior publications, namely, the Baily article of 1879; the Siemens patents of 1878; Deprez's article of 1880-4, and the Bradley application of May 9, 1887. As to Baily the court says: "Baily merely showed how to apply a series of successive impulses to the disk by an intermittent rotation of the field and thus produce Arago's rotation field with stationary magnets instead of a moving magnet, and he showed how the motion of the disk could be reversed. He conceived the idea of a uniform rotation by a manifestly imposible and impracticable construction. He did not claim to have established a continuous rotating field or to know any way in which a uniform rotation could be produced. He did not use alternating currents, but reversed currents. He was not dealing with the subject of the transmission of power. Defendants' expert admitted that his paper merely describes a laboratory experiment."

As to the allegation that the Siemens patent of 1878 was an anticipation, the Court says: "This patent is chiefly for means to convert motive power into electricity. It does not specificaly relate to or describe or fully show a system of apparatus for the transmission of power. It not only fails to refer to any difference of phase, or to point out how the armature and overlapping coils are to be coupled together to produce such phase, but it repeatedly describes the use of commutators in order to create a continuous or direct current. At this date it was not known that an alternating current machine could be used as a motor. Motors then were operated only by a direct or continuous current so far as the record shows. The 'suitable modifications' to change this machine into a motor are nowhere described; in view of the repeated reference to commutators, the modifications must be presumed to relate to such continuous current machines; and in view of the then state of the art such suitable modifications would have required such a series of experiments and such a departure from the existing theories and such development and application of devices in unexpected and non-analogous ways as would in themselves have constituted invention. Siemens himself, as late as 1884, and Alteneck, the other inventor of said Siemens patent, in 1881, admitted that they did not know that alternating currents could be used as motors. This evidence was objected to on the ground that the publications containing said statements are not duly proved, but the fact is established by other sufficient evidence."

The Court then takes up the Bradley application filed six months before the Tesla application, but regards it also as inadequate. "The single specific object of Bradley's construction stated in said specification was to obviate 'difficulties and limitations' in prior constructions wherein the machine was idle during a part of the time. He suggests that this may be done by rectifying one of the alternating currents by a commutator and then combining the two or by connecting each with a separate circuit. He does not show how he would use them in the latter case to operate a motor, nor did he indicate any combination of the alternate currents for a single motor or show that he had any conception of their use, if at all, otherwise than separately in single-phase motors.

"A comparison of the Bradley application prior to Tesla with the Bradley patent, issued subsequent to Tesla, shows that in the former he described a method and illustrated an apparatus designed to obviate the objections to a two-phase alternating currrent by combining both currents in one by means of a transformer, while from the latter he omitted this description and method and inserted figures which, while strikingly suggestive of the apparatus shown by Tesla, failed to show that he conceived the Tesla idea or sought to secure the object of Tesla's invention. For this reason, and further because Bradley's application is limited in scope, and ambiguous and indefinite; because it fails to show that he had any conception of the Tesla idea of 'the utilization of the motor for the purpose of progressively shifting the magnetic poles of a plurality of alternating currents by circuits which preserved the independence and differing time relation of their phases;' because, even if the idea had been first conceived by Bradley, it was not sufficiently described to disclose the principle or method of operation; because Tesla was the first to reduce this principle to practice, Bradley does not anticipate or limit."

As to the publications of Marcel Deprez of 1880-84, the Court concedes that Deprez not only disclosed the principle which Tesla utilized, but he gave a mathematical demonstration of the rotating field. But the only device possible to Deprez's mind was an electric compass. "All that Deprez demonstrated, therefore, was that if a field was made in which the field magnet varied relative to the brushes, or *vice versa*, the angle of variation would be indicated by the needle in another machine which would move quickly or slowly as the brushes and magnets shifted relative to each other and would indicate the new angle subtended between the brushes and the magnet. The only useful, practical application of this device was to attach it to a machine which would produce currents, and to use the earth or a ship to indicate the shift of position by means of a needle on top of the mast. This apparatus failed to teach any one that alternating currents could be used as a source of power in a motor. It was a mere indicator. It did not involve the utilization of two alternating currents differing in phase as a source of power in producing a continuous magnetic field. It did not depend upon any constant, regular, progressive currents, and, so far as the evidence shows, it was like the apparatus of Baily, confessedly a mere laboratory experiment. That Deprez did not conceive of the Tesla idea of utilizing regular, progressive, constant alternations of current is conclusively shown by his own statement in 1884 after the publication of this paper and after the invention of the Gaulard and Gibbs alternating current systems for lighting, when he published another paper in which he criticised the system and stated that one of the most serious objections to it was that it was not applicable to the transmission of power and adds: 'I must further remark that alternating currents are of no use in the transmission of power; they are suitable only for lighting purposes.' In fine, the evidence shows that, as Prof. Sylvanus Thompson says in his work on this general subject: 'Deprez's theorem bore no fruit; it remained a geometrical abstraction.'"

Judge Townsend then reviews the state of the art up to the time of Tesla's invention, and says that prior to it no alternating-current motors were in use, although there was an urgent demand for them. Six months later Tesla read his paper before the American Institute of Electrical Engineers and announced that previous efforts to utilize alternate currents had failed; that he had brought forth a novel system for the tarnsmission of power, and explained its theory and demonstrated its operation by exhibiting a working motor; and no one of the electricians present questioned his claim or criticized his apparatus.

Tesla first stated the discovery how these alternations could be thus utilized and showed the machine and method adapted for this purpose. He is entitled to a patent for this discovery as were the discoverers of the use of anthracite coal instead of bituminous coal, or of the hot blast instead of the cold blast, in the manufacture of iron, or of the practical application of electricity to the telegraph or telephone. Judge Blatchford once sustained a patent for insulating electric wires by means of gutta-percha, and said:

"The gist of the invention is the discovery of the fact that gutta-percha is a non-conductor of electricity, and the application of the fact to practical use. The claim is valid, even though a metallic wire covered with gutta-percha existed before the plaintiff's invention, if it was not known that gutta-percha was a non-conductor of electricity, and could be used to insulate the wire."—Colgate vs. Western Union Telegraph Company, 6 Fed. Cases, 86.

It is not necessary to go to this extent in sustaining these patents. The complainant may safely rest its case on the general principles laid down in the various decisions of the Supreme Court and extended and developed in Potts vs. Creager, *supra*.

Further than this, the Court says: "But if the evidence already considered be disregarded and it should be assumed that alternating and alternated currents were theoretically known equivalents, even then the argument of counsel for defendants does not appear to be sound. They contend that a superior result, by reason of the substitution of one known equivalent for another, does not constitute invention. But the first substitution or application of such theoretical equivalent to produce a new or non-analogous or unexpected result may involve invention. Tesla applied the alter*nating* current to do what the alter*nated* current had never before done, namely, to produce a new, unexpected and practical system of transmision of power. A careful study of the evidence has led to the conclusion that Tesla made a new and brilliant discovery. But even if this be incorrect, it is proved that by a new combination and arrangement of known elements, he produced a new and beneficial result never attained before. The technical defense of non-infringement by reason of the fact that defendants use only a motor, and that there is no allegation or proof of con-

spiracy with the owners of the plant which supplies the power, was not pressed on the argument, and as six days were spent in the discussion of the questions on the merits this point will not be discussed. If any amendment is necessary to cover these points it should be allowed. The contention of defendants that Tesla does not describe an operative machine is not satisfactorily proved. It is proved that in fact various practical motors have been manufactured according to his invention."

The question was urged by the defence as to the point that "independent" in the patents meant separated or "isolated." The Court held that "the claims, confessedly, cannot be read as requiring isolation of the circuits, but at most only such independence as is necessary for the purpose of producing a rotary field; that is, the connections must be such as not to interfere with the independency of the circuits which operate to shift the poles. The only practical result from defendants' use of three conductors instead of six is an improvement 'to regulate the action of the motor,' which result was anticipated by Tesla, and it is proved that it was known in the prior art that one of these arrangements was a substitute for the other. Inasmuch as the defendants have not invented any new idea, but have adopted an old contrivance which performs the same result in substantially the same way by a formal and unsubstantial change in means, and by circuits which while in some sense interdependent are operatively independent, and which preserve and utilize the vital element, independence of phase, these circuits must be held to be the equivalents of the independent circuits of the patent, the word independent being interpreted to mean *comparatively independent*, so as to embrace the true spirit and essence of the Tesla invention.

"This conclusion is supported by a great number of illustrations of similar uses of such independent conductors in the general field of the arts. As the expert for complainant has pointed out, in railroads, cash carriers, electric telegraphs, the tracks, the earth or a single wire, will serve as common but independently acting conductors. It does not seem necessary to further discuss this contention based on a technical verbal distinction. Defendants' three wires are operatively independent; they are actually independent while in action; they are independent enough to do the required work."

The Court touched briefly on the action of the Imperial Court of Germany presumed to affect adversely the Tesla patents, but saw no sufficient reason why the conclusion of that court should have any bearing on the question of infringement here.

Infringement of the first claim of patent No. 381,968 necessarily implies infringement of the method patent No. 382,280. The finding that the circuits of the defendants are independent, in the sense of the Tesla patents, is decisive against the defendants as to the infringement of the first and second claims of patent No. 382,279; and the field magnet of defendants' motor, while differing in some respects from that of the third claim of No. 381,968, is annular or ring-shaped within the meaning of said claim and infringes it.

The decision concludes as folows: "The search lights shed by defendants' exhibits upon the history of this art only serve to illumine the inventive conception of Tesla. The Arago rotation taught the school-boy 50 years ago to make a plaything which embodied the principle that a "rotating field could be used to rotate an armature." Baily dreamed of the application of the Arago theory by means of a confessedly impossible construction. Deprez worked out a problem which involved the development of the general theory in providing an indicator for a ship's compass. Siemens failed to disclose the "suitable modifications" whereby his electric light machine might be transferred into a motor, and Bradley is almost equally vague. Eminent electricians united in the view that by reason of reversals of direction and rapidity of alterations an alternating current motor was impracticable, and the future belonged to the commutated continuous current. It remained to the genius of Tesla to capture the unruly, unrestrained and hitherto opposing elements in the field of nature and art and to harness them to draw the machines of man. It was he who first showed how to transform the toy of Arago into an engine of power; the "laboratory experiment" of Baily into a practically successful motor; the indicator into a driver; he first conceived the idea that the very impediments of reversal in direction, the contradictions of alternations might be transformed into power producing rotations, a whirling field of force. What others looked upon as only invincible barriers, impassable currents and contradictory forces, he seized, and by harmonizing their directions utilized in practical motors in distant cities the power of Niagara.

"A decree may be entered for an injunction and an accounting as to all the claims in suit."

Messrs. F. H. Betts, Kerr, Page & Cooper, and L. E. Curtis, on the brief, appeared for the complainant; and Mitchell, Bartlett & Brownell for the defendants.

Tesla Patents Upheld.

An important electrical decision was handed down at New Haven, Conn., on August 29th by Judge Townsend, in the United States Circuit Court, in the case of the Westinghouse Electric and Manufacturing company against the New England Granite company.

It was on a final hearing on bill and answer raising questions of patentability and infringement of three patents granted to Nikola Tesla, May 1, 1888, for an electric-magnetic motor. The patents in suit relate to the art of electrical transmission of power by the use of mechanically generating alternating currents. They cover the rotating magnetic field.

A decree for an injunction and an accounting as to all claims in suit was granted.

INSULATION BY COLD.

THE discoveries and inventions of Nikola Tesla have of late been noticeable more for their ingenuity than for their practicality. Whether the latest belongs to this category or not, it is not our place to determine. It is a method for the insulation of electric conductors by immersing them in some medium that insulates when frozen, and by then keeping this below the freezing-point. Mr. Tesla thus describes his invention in a newspaper interview:

"Imagine a great trough extending, if you wish, across the continent. It must contain a quantity of water or some other substance which will freeze. From my experiments I judge that sawdust and water will prove most effective. For the purpose of transmitting the current long distances I shall use a thin metal tube capable of resisting three hundred pounds pressure to the square inch. This tube will be submerged in the substance which I intend to freeze.

"In the whole discovery the most interesting feature is the method I have devised for freezing the material in the trough. Five or six feet below the surface the ground itself is very cold. Here the trough would be buried. Through the tube there will then be forced a current of gas—probably hydrogen—reduced to a temperature of minus 200 degrees or thereabouts.

"This, under ordinary circumstances, will be sufficient to freeze the material surrounding the tube in the trough, and also to neutralize the heat which would be generated by the electricity."

Referring to the advantages that might be derived from this new system of insulation the inventor said:

"It has been known since the days of Faraday that an electrical current can not break through an insulation of ice. My success lies in discovering how practically to apply this truth. To show of what gigantic worth it may be needs but a moment. Grant that the invention has, as I believe, given to the world an almost perfect insulator, immediately there follow results which will directly or indirectly affect every manufacturing industry which in any way uses electricity.

"This will follow from the fact that no electricity will be lost in transmission. The cost of the new insulation will in the end be cheaper than that now used, and so it follows that the electricity which is to be utilized in a thousand different ways can be produced at a less cost. To telephone and telegraph companies, therefore, you see that my invention will be indispensable.

"Water-power converted into electricity can by the new method of insulation be carried thousands of miles. At present the loss of electricity due to unsatisfactory insulation makes this impossible. I have been considering the possibility of carrying the power of Niagara to this city, and find that it can be done with a loss of not more than one-half per cent. to one per cent.

"For the first time in history a power will be used for insula-

tion instead of a property. Deaths from contact with exposed wires will be prevented by the new method. The increase in the speed of exchange of telephone and telegraph messages will be pronounced after the adoption of my discovery.

"These are the important changes in the electrical world which will be wrought by this invention. There will be also innumerable indirect results."

Commenting upon all this *Electricity* (August 22) says editorially:

"This system of insulation, as will readily be seen, would entail the digging of trenches and laying of tubing, to say nothing of forcing a current of gas through the whole system, which, over a long distance, would entail an enormous initial expenditure of money. This would seem to be the principal objection to the system and one which would prohibit its adoption in carrying power to localities situated a hundred or more miles distant, where fuel could be obtained at reasonable prices. That such a system, if found practicable, would have its field of usefulness there is not the slightest doubt, but that field would be limited or not sufficiently extensive to warrant insulation manufacturers looking about for some other means of earning an honest living."

The Tesla Patent Decision.

Further details of the decision of Judge Townsend of the United States Circuit Court for the District of Connecticut, upholding the Tesla rotary-magnetic field patents in the case of the Westinghouse Electric and Manufacturing company against the New England Granite company, are of interest.

Judge Townsend, in sustaining Tesla's claims, directed attention to the sweeping changes brought about in the electrical arts by Tesla's inventions, and paid a strong tribute to the inventor's genius. In reviewing the history of electrical power transmission, the court referred to the earlier state of electrical science when direct current was alone used for the transmission of power, and pointed out the limitations which characterized this method. He then showed that efforts had been made to transmit power by the simple alternating current and that this system had proved inadequate, especially for variable loads. He then went on to state that at this stage of electric science, marked by the limitations of direct-current systems on the one hand and the impracticability of alternating-current systems on the other, Tesla's brilliant conception of the rotating field placed the transmission of power over considerable distances for the first time on a practical basis.

The court then took up in detail Tesla's three fundamental patents (Nos. 381,968, 382,280 and 382,279), covering respectively an electromagnetic motor, the transmission of power therefor, and specific designs of induction apparatus, and reviewed the respective position of the litigants. The defendant alleged that magnetic progression or rotation was not a new principle, but had been known in essence since Argo caused a copper disk to rotate by the rotation of an adjacent horseshoe magnet, subsequent to which Bailey had produced rotation in a similar disk by "an intermittent rotation of the field affected [effected?] by means of electromagnets."

Upon this point the court made an exhaustive analysis of the state of the art at that time, showing that Bailey had not used alternating currents to operate this motor, which was admitted by the defendant to be only a laboratory experiment.

The Westinghouse experts compared the operation of Bailey's intermittent field to the action of "propelling a boat with oars hung on pins so as to be incapable of feathering, and which are held rigidly in the water for a considerable time after each stroke before they are advanced for the next. It is evident that this method of propulsion would involve a large waste of power, since the oars would act alternately to propel and to stop the boat, and the method would be practically useless. Using the same analogy, the action of Tesla's continuously rotating field would be like that of the ordinary screw propeller, in which all the power is applied in a continuous push forward."

With reference to the Siemens and Gramme multiple-circuit machines and other early apparatus, the court cited the contentions of the defendant that these machines embodied in themselves the elements necessary to their operation as motors, and that with "suitable modifications," they would have shown the essential qualities of the Tesla apparatus. On this point the court held that whatever elements of this character these earlier machines may have possessed, such elements were at no time developed, and that their development would have required such a series of experiments, such a departure from then existing theories, and such development and application of devices in unexpected and non-analogous ways, as would in themselves have constituted invention. The court further said, "Siemens himself as late as 1884, and Alteneck, the other inventor of said Siemens' patent, admitted in 1881 that they did not know that alternating currents could be used as (in) motors," this statement being substantiated by sufficient evidence.

In 1887 C. B. Bradley made application for a patent on a dynamo-electric machine, which, the defendant contends, was a two-phase machine; but the court declared that the single specific object of Bradley in this construction was to "obviate difficulties and limitations" in prior constructions, and that he did not indicate any combination of the alternate currents for a single motor or show that he had any conception of their use, if at all, otherwise than separately in single-phase motors.

The court further held that Bradley's claims were limited in scope, were ambiguous and indefinite, and failed in showing any conception, on the inventor's part, of the Tesla idea of the production in a motor of a progressively shifting magnetic field by means of two or more independent alternating currents, differing in phase, and circuits which preserve the independent character and phase relation of such currets and added: "Even if the idea had been first conceived by Bradley, it was not sufficiently described to disclose the principle or method of operation. * * * Tesla was the first to reduce this principle to practice. Bradley does not anticipate or limit."

The defendant's chief reliance was upon the Marcel Deprez publications of 1880-84. In these Deprez had shown a device called a "comparer," in which a stationary ring of iron, carrying two independent windings, was employed. Into these two circuits currents of different strength were simultaneously thrown, the resultant polarity of the ring depending upon the ratio between the two current strengths. As a practical application of this device, Deprez describes the construction of a new form of compass, the needle of which was to respond to the varying current strengths induced in the two windings by changes in their position relative to the earth's magnetic axis. Deprez did not conceive even now of the Tesla idea of utilizing regular, progressive alternations of current, as is conclusively shown by his own statement, made in 1884, that "alternating currents are of no use in the transmission of power; they are suitable only for lighting purposes."

The court stated that, on the other hand, Tesla's underlying thought was "the use of the rapidly successive opposing alternation of the alternating current, regularly and constantly recurring in such differing phases as would not only prevent the alternations from stopping the armature, but would become a source of power. It was essential to the practical development of this idea that the alternations should rise and fall and succeed each other progressively and constantly and should be arranged, as counsel for complainant puts it, 'like the crank on a locomotive in which there is no dead center, but one crank is always pushing forward.'"

Such, then, was the status of the art in 1887, when Tesla filed his applications for patents. Prior to his invention alternating-current motors were not in use, although there had been an urgent demand for some practical means of utilizing alternating currents for power transmission. This demand had been emphasized by the rapid development of the electrical art in other directions, but the leading electricians of the day concurred with Deprez in his declaration that alternating currents could not be used for the transmission of power.

It was at this juncture that Tesla patented his invention, introducing a new method, a new means and a new terminology into the art. The prompt recognition of Tesla among electricians, as the original inventor of a new system and of means for its practical application is abundantly supported by the literature of that day. Tesla did not originate the parallelogram of forces or discover the rotary field, but he was the first to do practically what Bailey had said could be done by an impracticable, if not impossible, apparatus, and what others had vaguely said could be done without indicating the means.

Judge Townsend declared that Tesla, having stated the discovery by himself of a method whereby alternating current could be utilized for power, and having shown the actual machine and method, was as much entitled to a patent for this discovery as were the discoverers of the application of electricity to the telegraph and the telephone, and he added: "A careful study of the evidence has led to the conclusion that Tesla made a new and brilliant discovery. But even if this be incorrect, it is proved that by a new combination and arrangement of known elements, he produced a new and beneficial result never attained before."

The defendant tried to establish a point by showing that in the construction defended none of the transmitting circuits of the system consisted of two conductors specially devoted to any one of the differing phase currents, whereas the patents show two line conductors especially devoted to a single one of the differing phase currents. The court, in commenting upon this point, called attention to the question as to the construction to be placed upon the word "independent" in the Tesla patents, the complainant contending that Tesla's broad invention was the production in a motor of a progressively shifting magnetic field by means of independent alternating currents differing in phase and circuits which preserve the independent character and phase relation of the currents, while the defendant alleged that the words used in Tesla's patent ("induced circuits connected independently to corresponding circuits in the motor") referred to the physical relations which exist, and not to any result produced. But in Tesla's original specification he says: "By 'independent' I do not mean to imply that the circuits are necessarily isolated from one another, for in some instances there might be electrical connections between them to regulate or modify the action of the motor without necessarily producing a new or different action." This clause of Tesla's specification fully answers the last contention of the defendant, who is shown not to have invented any new idea but to have adopted an old contrivance which performs the same result in substantially the same way by a formal and unsubstantial change in means.

In conclusion, Judge Townsend referred eloquently to the genius of Tesla in seizing and adapting to purposes of utility what others had long looked upon as contradictory forces and impassable barriers. He said: "The searchlights shed by defendant's exhibits upon the history of this art only serve to illumine the inventive conception of Tesla. The Arago rotation taught the schoolboy 50 years ago to make a plaything which embodied the principle that a rotating field could be used to rotate an armature. Bailey dreamed of the application of the Arago theory by means of a confessedly impossible construction. Deprez worked out a problem which involved the development of the general theory in providing an indicator for a ship's compass. Siemens failed to disclose the 'suitable modifications' whereby his electric-light machine might be transferred [transformed] into a motor, and Bradley is almost equally vague. Eminent electricians united in the view that by reason of reversals of direction and rapidity of alternations, an alternating-current motor was impracticable, and the future belonged to the commutated continuous current.

"It remained to the genius of Tesla to capture the unruly, unrestrained and hitherto opposing elements in the field of nature and art and to harness them to draw the machines of man. It was he who first showed how to transform the toy of Arago into an engine of power, the 'laboratory experiment' of Bailey into a practically successful motor, the indicator into a driver. He first conceived the idea that the very impediments of reversal in direction, the contradictions of alternations, might be transformed into power-producing rotations, a whirling field of force. * * * A decree may be entered for an injunction and accounting as to all the claims in suit."

,lectrical Review

THE PIONEER ELECTRICAL WEEKLY OF AMERICA.

XVII. No. 12. NEW YORK, WEDNESDAY, SEPTEMBER 19, 1900. ISSUED WEEKLY.

On another page of this issue is given, practically in full, the text of the decision lately rendered by Judge Townsend, of the United States Circuit Court, in a suit alleging infringement of the patents granted to Mr. Nikola Tesla, upon the polyphase system of electrical transmission of power. The opinion reflects no little credit upon the learned judge's knowledge of electro-technical subjects. Whatever may be the history of the development of the polyphase system, there is no doubt that it has done more than any other single invention in the field of electrotechnics in the last fifteen years to advance and make possible the greater exploitation of electrical industries that we see about us to-day. The recognition given by Judge Townsend to Mr. Tesla is one that must be gratifying to him, and the text of the opinion, even to those not interested in the particular features of the matter in litigation, will be of peculiar interest as bearing upon the importance of the newer applications of the alternating current.

THE TESLA PATENTS.

SWEEPING DECISION IN FAVOR OF THESE PATENTS BY THE UNITED STATES CIRCUIT COURT.

Judge Townsend of the United States Circuit Court of Connecticut, recently handed down the decision sustaining the three Tesla patents of May 1, 1888. These patents are numbered 381,968, 382,280 and 382,279. The suit was that of the Westinghouse Electric and Manufacturing Company against the New England Granite Company.

The decision is a very sweeping and interesting one to the entire electrical fraternity, and we present it almost in full herewith.

TOWNSEND, District Judge.

The patents in suit relate to the art of electrical transmission of power by the use of mechanically generated alternating electric currents.

It is, of course, understood that the real nature of electricity is still unknown, and that the nomenclature used herein, such as "currents," "flowing," etc., are merely convenient technical terms to indicate certain known results.

The electric current induced by a mechanical generator—a dynamo—is necessarily alternating in character; that is, alternating in direction, so that the current, acting on an armature, first tends to actuate it in one direction and then reverses said effect and neutralizes such actuation. Such a current flows uninterruptedly and regularly, but rises in intensity from zero to maximum and falls from maximum to zero, and then repeats said variations in the opposite direction. Its curve of increase or decrease of strength is indicated by a wave line or sine curve.

Every mechanically generated current is naturally and originally an alternating current. Formerly it was not considered practicable to use mechanically generated currents until their alternations were straightened out by means of commutators which reversed the direction of the current so as to make it flow continually through the conductors. A current which is periodically reversed by a commutator which thus breaks the current between the changes in direction and takes off the current in sections, is known as a reversed or alternating current. This distinction between an alternating and an alternated current should be carefully noted. An alternating current continues to act in opposite directions as originally generated. An alternated current has been so reversed that the whole flows in one direction and is then known as a continuous current. When so reversed by commutators as to become continuous, the current loses certain characteristics essential to its highest efficiency.

Prior to the Tesla inventions, only reversed or alternated electric currents were used for the transmission of power. The application of this system for the transmission of power was limited, for various reasons; among others because a large current could not be safely used at sufficiently high pressure for long distances. On the other hand, the pure alternating current was practically unlimited in volume and pressure, and a change of pressure could be economically effected by the use of a transformer.

Prior to Tesla's inventions, however, these rapid alternations of the alternating current prevented the motor from starting its revolution and interfered with its continuing in operation, except when in synchronism with the generator. It was therefore impracticable for varying loads.

The problem which was presented to Nikola Tesla, and which he successfully solved was: How to overcome the difficulties attendant upon the use of the alternating currents so that their inherent vitality and untrammeled energy might be utilized for the unlimited transmission of power.

In an electric motor, the tendency of the armature is always toward the pole or point of maximum magnetic intensity. If a loosely-pivoted or freely-moving magnetic bar or armature be suspended midway between two coils of insulated wire wound in opposite directions on a soft-iron bar, and one of the coils is electrically energized, north and south poles will be formed at the ends of the soft iron bar—their location depending upon which coil is energized; but if both coils be equally energized, the two poles will neutralize each other and cause a resultant north pole midway between the coils. If, now, the current in one coil be made weaker than in the other, said pole will move toward the coil of greater electrical energy. The magnetic bar or armature will follow the shifting position of the pole, and by thus gradually varying the energy in the coils, the armature may be alternately caused to move from the pole of one coil along toward the pole of the other coil.

The alternating current generated by an electrical machine, as before stated, constantly varies from maximum intensity to zero in one direction, and then from zero to maximum intensity in the opposite direction.

In the invention of the patents in suit, Tesla availed himself of this characteristic feature of alternating currents in the following way:

In constructing a motor, he arranged on an annular soft-iron core, two pairs of magnetizing coils, each pair at right angles to the other, that is, one coil of one pair at the top and one at the bottom, and one coil of the other pair at each opposite side of said core, and mounted an armature in the centre. Then, connecting them with an alternating-current generator, he caused a current from one pole of said generator to pass through one pair of coils and a current from the other to pass through the other pair.

If the cycles of alternating currents be regarded as divided into 360 degrees, then, as shown in the Tesla illustrations, they will have a relative displacement of 90 degrees. In such position the lines of magnetic force traversing the two coils will be at maximum in one while at minimum in the other. This relative displacement marks the differing phase or time relation of the two currents.

The effect of passing two equal currents through said coils would be to cause the pole of maximum intensity to pass midway between the poles of the respective pairs of coils. But the effect of the ordinary operation of the generator as before explained was to cause the current in each pair of coils to vary from zero to maximum and to zero and then to shift in the opposite direction, the intensity of the current flowing to one pair of coils being at maximum while that of the other was at zero and one increasing while the other decreased, and the result being to shift said poles so as to make them travel entirely around said core.

Fifteen days after the issue of the patents in suit, Tesla read before the American Institute of Electrical Engineers a paper entitled "A New System of Alternate-Current Motors and Transformers," in which *inter alia*, he said:

"The transmission of power, on the contrary, has been almost entirely confined to the use of continuous currents, and, notwithstanding that many efforts have been made to utilize alternate currents for this purpose, they have, up to the present, at least as far as known, failed to give the result desired."

"The subject which I now have the pleasure of bringing to your notice is a novel system of electric distribution and transmission of power by means of alternate currents, affording peculiar advantages, particularly in the way of motors, which I am confident will at once establish the superior adaptability of these currents to the transmission of power and will show that many results heretofore unattainable can be reached by their use; results which are very much desired in the practical operation of such systems and which can not be accomplished by means of continuous currents.

"Before going into a detailed description of this system, I think it necessary to make a few remarks with reference to certain conditions existing in continuous-current generators and motors, which, although generally known, are frequently disregarded.

"In our dynamo machines, it is well known, we generate alternate currents which we direct by means of a commutator, a complicated device, and, it may be justly said, the source of most of the troubles experienced in the operation of the machines. Now, the currents so directed can not be utilized in the motor, but they must—again by means of a similar unreliable device—be reconverted into their original state of alternate currents. The function of the commutator is entirely external, and in no way does it affect the internal working of the machines. In reality, therefore, all machines are alternate-current machines, the currents appearing as continuous only in the external circuit during their transit from generator to motor. In view simply of this fact, alternate currents would commend themselves as a more direct application of electrical energy, and the employment of continuous currents would only be justified if we had dynamos which would primarily generate, and motors which would be directly actuated by such currents.

"But the operation of a commutator on a motor is two-fold; firstly, it reverses the currents through the motor; and, secondly, it effects, automatically, a progressive shifting of the poles of one of its magnetic constituents. Assuming, therefore, that both of the useless operations in the system, that is to say, the directing of the alternate currents on the generator and reversing the direct currents on the motor be eliminated, it would still be necessary, in order to cause a rotation of the motor, to produce a progressive shifting of the poles of one of its elements, and the question presented itself: How to perform this operation by the direct action of alternate currents? I will now proceed to show how this result was accomplished.

The claims in issue in Patent No. 381,968 are as follows:

"1. The combination, with a motor containing separate or independent circuits on the armature or field magnet, or both, of an alternating-current generator containing induced circuits connected independently to corresponding circuits in the motor, whereby a rotation of the generator produces a progressive shifting of the poles of the motor, as herein described.

"3. The combination, with a motor having an annular or ring-shaped field magnet and a cylindrical or equivalent armature, and independent coils on the field magnet or armature, or both, of an alternating-current generator having correspondingly independent coils, and circuits including the generator coils and corresponding motor coils in such manner that the rotation of the generator causes a progressive shifting of the poles of the motor in the manner set forth."

That of Patent No. 382,280, is as follows:

"The method herein described of electrically transmitting power, which consists in producing a continuously-progressive shifting of the polarities of either or both elements (the armature or field magnets or magnets) of a motor by developing alternating currents in independent circuits, including the magnetizing coils of either or both elements, as herein set forth."

The claims in issue of Patent No. 382,279, are as follows:

"1. The combination, with a motor containing independent inducing or energizing circuits and closed induced circuits, of an alternating-current generator having induced or generating circuits corresponding to and connected with the energizing circuits of the motor, as set forth.

"2. An electro-magnetic motor having its field magnets wound with independent coils and its armature with independent closed coils, in combination with a source of alternating currents connected to the field coils and capable of progressively shifting the poles of the field magnet, as set forth.

"3. A motor constructed with an annular field magnet wound with independent coils and a cylindrical or disk armature wound with closed coils, in combination with a source of alternating currents connected with the field-magnet coils and acting to progressively shift or rotate the poles of the field, as herein set forth."

Complainant's theory of the Tesla invention is shown in the following citation from the brief:

"It will be observed that to produce a shifting of the magnetic pole in one case, and a consequent movement of an armature corresponding thereto, each coil A and B must be traversed by a current of variable strength, and in order to secure uniformity of the movement of the pole or resultant it follows that the variations in strength of current in the two coils must be gradual and preserve definite relations to each other, throughout the cycle of variation in strength which the two currents undergo.

"This principle lies at the foundation of Tesla's brilliant discovery, the gist of which was the utilization of the alternating currents generated by an alternating-current dynamo or generator for effecting such shifting of the magnetic poles or resultant attractive forces upon the armature of a motor, and thus causing such armature to rotate in response thereto.

"His broad invention, expressed in a few words, was the production in a motor of a progressively-shifting magnetic field (or pole) by means of two

or more independent alternating currents, differing in phase, and circuits which preserve the independent character and phase relation of such currents."

Defendant's position is shown by the following extract from their briefs:

"Referring further to the apparatus of Tesla, Waterman says (Rec., p. 52): 'Briefly then, the apparatus consists of a ring held magnet having one set of coils tending to magnetize it on one diameter and another tending to magnetize it on a diameter at right angles to the first, and these sets of coils or circuits are so connected to a proper generator as to be traversed by currents such as would be generated by two coils at right angles to one another rotating in a two-pole field.' It will be seen from this that complainants claim a broad discovery and a broad invention based thereon. Defendants, on the other hand, contend that the alleged discovery was old, that its application was old, and that, since the days of Arago, there was never any room for a broad invention in the 'obvious' application of the alleged 'discovery;' and that the present state of the art has been developed from the earlier art including Arago's rotation by the mere application of engineering skill possessed by skilled electricians who have applied their knowledge as the progressive demands of the times called for it, supplemented by inventions special to the motor or the generator or the connecting circuits severally, and in no way entitling Tesla or any other patentee to prevent the sale of generators and motors through the ownership of an all-controlling patented 'system.'"

The well-known Arago rotation is described as follows:

"Arago's method of producing rotation in a copper disk consists of suspending it by its centre so as to make it lie horizontally above the poles of a horseshoe magnet and then rotating the magnet about a vertical axis. The rotation of the disk is due to that of the magnetic field in which it is suspended; and we should expect that if a similar motion of the field could be produced by any other means the result would be a similar motion of the disk."

The chief contention of the defendants is that there is no substantial difference in character between alternating and reversed currents and that the art of electric lighting illustrated in the alleged anticipations showed such an analogous use of reversed currents that the substitution of alternating for reversed currents did not involve invention.

Defendant further contends that the principle of reversibility was well known in the art, and as the inventors of electric lighting apparatus state that by a reversal of their action, power may be produced, Tesla is deprived of all claim to the exercise of the inventive faculty. That is, that the same apparatus may be used as a generator or dynamo-electric machine or may be reversed and used as a motor or electro-dynamic machine.

(This word "reversibility" has no relation in this connection to the word "reversed" as applied to currents.)

In support of their contentions defendants chiefly rely upon four prior publications, namely, the Baily article, of 1879; the Siemens patents, of 1878; Deprez's article of 1880-1884, and the Bradley application of May 9, 1887.

[The decision at this point quotes from different authorities at some length, from Siemen's British patent of 1878 for improvement in apparatus for dynamical production of electricity and its regulation when applied for illumination. The statement is also made that on May 9, 1887, about six months before the filing of the Tesla patents, Charles S. Bradley filed his application for his dynamo-electric machine, a generator for converting power into electricity. Judge Townsend continues as follows:]

A comparison of the Bradley application prior to Tesla with the Bradley patent issued subsequent to Tesla shows that in the former he described a method and illustrated an apparatus designed to obviate the objections to a two-phase alternating current by combining both currents in one by means of a transformer, while from the latter he omitted this description and method and inserted figures which, while strikingly suggestive of the apparatus shown by Tesla, failed to show that he conceived the Tesla idea or sought to secure the object of Tesla's invention.

For this reason, and further because Bradley's application is limited in scope, and ambiguous and indefinite; because it fails to show that he had any conception of the Tesla idea of "the utilization of the motor for the purpose of progressively shifting the magnetic poles of a plurality of alternating currents by circuits which preserved the independence and differing time relation of their phases;" because, even if the idea had been first conceived by Bradley, it was not sufficiently described to disclose the principle or method of operation; because Tesla was the first to reduce this principle to practice, Bradley does not anticipate or limit.

Defendants' chief reliance is on the Marcel Deprez publications of 1880-1884, and rightly so, for Deprez not only disclosed the principle which Tesla utilized, but he gave a mathematical demonstration of the rotating field. Complainant's expert's admission on this point is as follows:

"The article demonstrated mathematically the fact, which is also stated in the Tesla patents, that the polar line of an annular magnet may be shifted about through the entire circumference of the ring by the action of two magnetizing forces properly related."

[Judge Townsend here quotes from Deprez's writings, and then says:]

All that Deprez demonstrated, therefore, was that if a field was made in which the field magnet varied relative to the brushes, or *vice versa*, the angle of variation would be indicated by the needle in another machine which would move quickly or slowly as the brushes and magnets shifted relative to each other and would indicate the new angle subtended between the brushes and the magnet. The only useful, practical application of this device was to attach it to a machine which would produce currents, and to use the earth or a ship to indicate the shift of position by means of a needle on top of the mast. This apparatus failed to teach any one that alternating currents could be used as a source of power in a motor. It was a mere indicator. It did not involve the utilization of two alternating currents differing in phase as a source of power in producing a continuous magnetic field. It did not depend upon any constant, regular, progressive currents, and, so far as the evidence shows, it was like the apparatus of Baily, confessedly a mere laboratory experiment. That Deprez did not conceive of the Tesla idea of utilizing regular, progressive, constant alternations of current is conclusively shown by his own statement in 1884, after the publication of this paper and after the invention of the Gaulard and Gibbs alternating-current systems for lighting, when he published another paper in which he criticised the system and stated that one of the most serious objections to it was that it was not applicable to the transmission of power, and adds: "I must further remark that alternating currents are of no use in the transmission of power; they are suitable only for lighting purposes."

In fine, the evidence shows that, as Professor Silvanus Thompson says in his work on this general subject: "Deprez's theorem bore no fruit; it remained a geometrical abstraction."

The underlying thought disclosed and applied in the Tesla patents is such a use of the rapidly successive opposing alternations of the alternating current regularly and constantly recurring in such differing phases as would not only prevent the alternations from stopping the armature, but would become a source of power. It was essential to the practical development of this idea that the alternations should rise and fall and succeed each other progressively and constantly should be arranged, as counsel for complainant puts it, "like the crank on a locomotive in which there is no dead centre, but one crank is always pushing forward." Tesla's invention, considered in its essence, was the production of a constantly rotating or whirling field of magnetic forces for power purposes by generating two or more displaced or differing phases of the alternating current, transmitting such phases, with their independence preserved, to the motor, and utilizing the displaced phases as such in the motor.

Baily does not describe the use, with alternating currents, of displaced phases. He only describes the producing of intermittently shifting poles by means of a commutator or reverser which is just what Tesla disclaims. Neither Siemens nor Bradley describes the utilization of such displaced phases of alternating currents with their independence preserved in a motor.

Deprez describes a parallelogram of forces and its application to indicate at any given moment the angle between two parts of a source of current. He did not contemplate the use of alternating currents nor utilize their continuous and constant movement nor did he utilize said current to produce power, nor did he have any idea of a whirling field of forces to propel a motor.

What then was the status of the art in 1887 when Tesla filed these applications?

Nine years had elapsed since the grant of the Siemens patent which, according to counsel for defendants, "is a full disclosure of the subject matter in issue in Patents Nos. 381,968 and 382,280," and its "references . . . at the hands of the skilled electrician . . . would naturally, and as a matter of course, have resulted in an organization of elements constituting a system for the electrical transmission of power and embodying essentially the system" of said patents. Eight years had elapsed since Baily. It was four years since Marcel Deprez's article, according to defendant's counsel, "described the very thing that complainant claims is Tesla's discovery and explained the theory of operation," of an apparatus which "is an operative two-phase alternating-current generator supplying two-phase alternating currents to produce a rotating field in a motor" similar to the Tesla motor.

Prior to Tesla's invention no alternating-current motors were in use.

Although there has been an urgent demand for some practical means of utilizing alternating currents for transmission of power none had been found.

The continuous and unparalleled development of the electric art had for years increasingly emphasized the want of an electric motor capable of distributing power for long distances and had vainly called for the solution of the problem of the use of alternating currents for this purpose; the leading electricians of the day concurred with Deprez in his declaration after he had devised his comparateur that alternating currents could not be utilized in the transmission of power and that the future belonged to continuous currents.

In these circumstances Tesla patented his invention and thus first disclosed the method and apparatus, now generally known as the Tesla polyphase inventions, and introduced a new method, a new means and a new terminology into the art. Six months later he read his paper before the American Institute of Electrical Engineers and announced that previous efforts to utilize alternate currents had failed; that he had brought forth a novel system for the transmission of power, and explained its theory and demonstrated its operation by exhibiting a working motor; and no one of the electricians present questioned his claim or criticised his apparatus.

The statements made by electricians at said meeting are supported by abundant quotations from the contemporaneous literature of the day, and it does not appear that the recognition of Tesla as an original inventor of said system and of the means for its practical application was ever disputed until this suit was brought.

There is nothing in the record to detract from the claims then made. Tesla did not discover the parallelogram of forces; he did not discover the rotary field; but he was the first to explain how to do practically what Baily had said could be done by an impracticable infinity of magnets, and others had said it could be done, but without showing how it could be done. He harmonized the hitherto opposing alternations, while preserving their character and power.

Since the date of the Tesla patents in suit

there has been a revolution in the art due to the utilization of the means therein described.

The contention that the transfer from the electric light art to the electric power art did not involve invention can not be maintained.

Even if it be assumed that the art of electric lighting is in a sense analogous to that of electrical transmission of power, the result was new and unexpected. It has been already shown in what respects a reversed current differs from an alternating current. The question as to how far they are alike is of minor importance because it is admitted that the reversed or broken current is not the same for the practical purposes to which this invention is especially adapted. Therefore, although Deprez, in one of his publications, suggested that his system might be used for an impracticable and almost infinitesimal amount of power, the fact that these currents had never been practically used for any such purpose and can not, even now, be practically used for currents of high potential, shows that it required invention to select from an art that particular kind of current which was necessary for the production of the best results, and to adapt the mechanism of an art analogous or non-analogous, to its practical application.

The very fact that all the earlier electricians assumed or asserted that reversed and alternating currents were the equivalents of each other, was one of the errors which retarded the Tesla discovery, and the practical application of the polyphase principle.

The view most favorable to the contention of the defendants upon all the evidence presented, may be fairly stated thus:

Prior inventors had stated that electric light machines could be so reversed as to furnish power, although it is not proved that any one had shown a method for their use or the practical application thereof, or had ever made such practical application.

No prior publication explained how to utilize this alleged well-known reversibility and no prior machine applied it.

To the question why, if it was so obvious that the operation of the apparatus might be reversed and alternating currents then used, such method was not put in practical operation, the only answer of defendants is that "there had been up to 1885 no commercial system of distribution of alternating currents." But if this is so, is it not because the foremost electrical experts throughout the world had united in the opinion after repeated futile experiments that alternating currents were useless for the transmission of power and that the future belonged to continuous currents?

"The apparent simplicity of a new device often leads an inexperienced person to think that it would have occurred to any one familiar with the subject, but the decisive answer is that with dozens and perhaps hundreds of others laboring in the same field, it had never occurred to any one before." Potts *vs.* Creager, 155 U. S., 597.

Siemens, chiefly relied on to support this contention, does not describe any mode of using alternating currents, does not refer to the use of commutators, and only refers to the use of said apparatus as an electro-dynamic machine "with suitable modifications" which are nowhere described.

The impracticability as motors of reversed currents induced by commutators, shows that Siemens, Baily and others did not discover the Tesla invention; they were discussing electric light machines with commutators.

Tesla first stated the discovery how these alternations could be thus utilized and showed the machine and method adapted for this purpose. He is entitled to a patent for this discovery as were the discoverers of the use of anthracite coal instead of bituminous coal, or of the hot blast instead of the cold blast, in the manufacture of iron, or of the practical application of electricity to the telegraph or telephone. Judge Blacthford once sustained a patent for insulating electric wires by means of gutta-percha, and said:

"The gist of the invention is the discovery of the fact that gutta-percha is a non-conductor of electricity, and the application of the fact to practical use. The claim is valid, even though a metallic wire covered with gutta-percha existed before the plaintiff's invention, if it was not known that gutta-percha was a non-conductor of electricity, and could be used to insulate the wire." Colgate *vs.* Western Union Telegraph Company, 6 Fed. Cases, 86.

It is not necessary to go to this extent in sustaining these patents. The complainant may safely rest its case on the general principles laid down in the various decisions of the Supreme Court and extended and developed in Potts *vs.* Creager, *supra.*

But if the evidence already considered be disregarded, and it should be assumed that alternating and alternated currents were theoretically-known equivalents, even then the argument for counsel for defendants does not appear to be sound. They contend that a superior result, by reason of the substitution of one known equivalent for another, does not constitute invention. But the first substitution or application of such theoretical equivalent to produce a new or non-analogous or unexpected result, may involve invention. Tesla applied the alternating current to do what the alternated current had never before done; namely, to produce a new, unexpected and practical system of transmission of power.

A careful study of the evidence has led to the conclusion that Tesla made a new and brilliant discovery. But even if this be incorrect, it is proved that by a new combination and arrangement of known elements, he produced a new and beneficial result never attained before.

The technical defense of non-infringement by reason of the fact that defendants use only a motor, and that there is no allegation or proof of conspiracy with the owners of the plant which supplies the power, was not pressed on the argument, and, as six days were spent in the discussion of the questions on the merits, this point will not be discussed.

If any amendment is necessary to cover these points it should be allowed.

The contention of defendants that Tesla does not describe an operative machine, is not satisfactorily proved. It is proved that, in fact, several practical motors have been manufactured according to his invention.

The model of the particular patented construction selected for this proof, claimed to correspond most nearly to defendants' construction, failed to show a capacity of self-starting, and, when once started, revolved in either direction; but complainant showed on the hearing various differences between the construction shown in the drawing of the patent and the model, which, it was claimed, accounted for the failure.

The defendants use a three-phase transmitting system comprising a three-phase generator, three transformers and a three-phase motor. The argument based on the use of transformers was not pressed. . . .

The serious question raised in this branch of the case is as to the construction of the word " independent" in the patents. Counsel for defendants contends that "the word used in the patent evidently refers to the physical relations which exist and not to any result produced." Counsel for complainant contends that Tesla's "broad invention . . . was the production in a motor of a progressively shifting magnetic field by means of . . . independent alternating currents differing in phase, and circuits which preserve the independent character and phase relation of such currents."

The specifications and drawings of said patents describe and show six independent transmitting wires which are repeatedly referred to as constituting independent circuits, and the claims emphasize this independency. In defendants' motor the coils of generator and motor are so interconnected that each line wire not only serves as a conductor for its own phase, but also for the other currents.

Defendants' contention is fairly stated by counsel for complainant as follows:

"The defendants contend that currents of electricity belonging to each of the circuits are, therefore, at times all flowing in the same wire or wires, and that at certain instants in the operation of the same; *i. e.,* when each of the single transmission wires is, for an incredibly short period, transmitting no potential (*i. e.,* change from plus to minus)—two of the coils of the motor are supplying current to the third. . . . They cite the admission of Mr. Waterman that 'analytically' it is perfectly true that currents of electricity of differing phase may be at times regarded as simultaneously flowing in the same circuit."

This statement of Waterman, however, should be read in connection with his further statement, as follows:

"The net result of it all is that in a manner more or less complex to follow, these electromotive forces so cancel out that there is in each circuit a current differing in phase by 120 degrees from the current in each of the others, so that in the motor it is not possible to tell how the current got there, or over what kind of a circuit. (*i. e.,* whether over a three-wire or a six-wire circuit.)"

Counsel for defendants argue:

"That the term independent as used by Tesla means such separation as is consistent with having the complete circuits traversed by the same currents—currents which at any and every point are of the same quantity, intensity and phase, so that, as Mr. Clarke puts it, each motor circuit receives its current from a corresponding generator circuit and from no other. It can not refer to circuits which are interdependent in such sense that two of the circuits are at times strictly in series with one another and in multiple with the third, and so are not 'independent' in any sense. The whole system is an interdependent and not an independent system."

The following significant statement, however, is found near the end of the specification of the first patent, No. 381,968:

"By 'independent' I do not mean to imply that the circuits are necessarily isolated from one another, for, in some instances there might be electrical connections between them to regulate or modify the action of the motor without necessarily producing a new or different action."

The claims, therefore, confessedly can not be read as requiring isolation of the circuits but at most only such independence as is necessary for the purpose of producing a rotary field; that is, the connections must be such as not to interfere with the independency of the circuits which operate to shift the poles.

The only practical result from defendants' use of three conductors instead of six is an improvement "to regulate the action of the motor," which result was anticipated by Tesla as above, and it is proved that it was known in the prior art that one of these arrangements was a substitute for the other.

Inasmuch as the defendants have not invented any new idea, but have adopted an old contrivance which performs the same result in substantially the same way by a formal and unsubstantial change in means, and by circuits which, while in some sense interdependent, are operatively independent, and which preserve and utilize the vital element independence of phase, these circuits must be held to be the equivalents of the independent circuits of the patent, the word independent being interpreted to mean operatively independent, so as to embrace the true spirit and essence of the Tesla invention.

This conclusion is supported by a great number of illustrations of similar uses of such independent conductors in the general field of the arts. As the expert for complainant has pointed out, in railroads, cash carriers, electric telegraphs, the tracks, the earth or a single wire, will serve as common but independently-acting conductors.

It does not seem necessary to further discuss this contention based on a technical verbal distinction.

Defendants' three wires are operatively independent; they are actually independent while in action; they are independent enough to do the required work.

This case involves a diversity of complicated questions of the scope and effect of certain language, of the prior art, and of the operation of electrical apparatus. All these questions have been exhaustively discussed with singular ability and learning by the able counsel herein.

If the contentions of defendants as to the scope of the patents in suit are proved the question of infringement of the patented independent circuits is not free from difficulty. If independence means isolation the patents are valueless. But if complainant's contention is correct, and if Tesla is entitled now

to the broad claim which no one denied when he announced it to the American Institute of Electrical Engineers as his "novel system of electrical distribution and transmission of power by means of alternate currents . . . which will at once establish the superior adaptability of these currents to the transmission of power and will show that many results heretofore unattainable can be reached by their use," then there can be no question that defendants have infringed. The foregoing language has been again quoted in order to emphasize how consistently at the end of 10 years after a review of all possible questions Tesla stands upon his original statement of invention.

Infringement of the first claim of Patent No. 381,968, necessarily implies infringement of the method Patent No. 382,280. The finding that the circuits of the defendants are independent, in the sense of the Tesla patents, is decisive against the defendants as to the infringement of the first and second claims of Patent No. 382,279; and the field magnet of defendants' motor, while differing in some respects from that of the third claim of No. 381,968, is annular or ring-shaped within the meaning of said claim and infringes it.

At the close of the defendants' brief is printed the "Decision of the Imperial Court of Germany on Tesla Patent." The only reference thereto in said brief is in the statement that in said suit "brought to obtain a cancellation of Tesla's patents, that a German patent to one Haselwander (including the rotary-current system employed by defendants) was partially annulled because of the publication of this American patent to Bradley" and in the following statement:

"It should also be mentioned that the Imperial Court held that the system employed by defendants does not infringe the German Tesla patent corresponding to the patents involved in this suit —that court holding with us that our system is a dependent system and not having the independent circuits of the Tesla patents and inventions."

It is somewhat difficult to determine, from said opinion, the scope of the issues involved, but it appears that some German firm had applied to have two Tesla German patents canceled on the ground that they have not been worked, but "have only been used to the disturbance of the electro-technical industry in Germany." Tesla, as defendant, admitted that he had not actually worked his invention, but had fulfilled his duty by a license to a firm which had pledged itself to work the patents, and, furthermore, that certain alleged infringers, by using a rotary-current, three-wire system, which seems to have been substantially like that of defendants herein, had "worked" his invention, and thereby saved him from the statutory penalty. The court held as follows:

"'By independent is not meant to be expressed that the circuits are necessarily insulated from each other, since in single cases electrical connections can exist between them in order to regulate the working of the motor, without necessarily producing a new or another manner of working,' then also nothing is gained for him thereby. Entirely disregarding the fact that after the striking out of the sentence, which clearly occurred in order to avoid unclearness, the independence of the circuits is only so to be understood as is shown from the drawing and description—namely, as conditioned by a completely independent outgoing and return conductor—there would also never be able to be read into the stricken-out sentence that therein the linking of the circuits in the meaning of the rotary-current system had been thought of, for this linking removes the independence of the circuits, while the erased sentence will only admit such connections as permit the independence of the circuits to exist."

But this statement is a mere *obiter dictum*. The explanatory language relied upon by complainant in the patent here in suit has been stricken out of said German patent. The decision was upon two patents not shown to be the same as those herein in suit; the applications therefor were not filed until May, 1888, and not until after the Tesla invention had been described in a printed publication. But even this decision is to be construed as insisting upon a construction unfavorable to that here contended for by complainant, it should only be considered in connection with the foregoing facts. Here, the question of independence is directly presented, on a different issue, in view of a different state of the art, upon a different patent, from which the explanation of the word "independent" has not been erased. No sufficient reason has been shown why the conclusion of the German court should be followed in determining the question of infringement herein.

The search lights shed by defendants' exhibits upon the history of this art only serve to illumine the inventive conception of Tesla. The Arago rotation taught the schoolboy 50 years ago to make a plaything which embodied the principle that a "rotating field could be used to rotate an armature." Baily dreamed of the application of the Arago theory by means of a confessedly impossible construction. Deprez worked out a problem which involved the development of the general theory in providing an indicator for a ship's compass. Siemens failed to disclose the "suitable modifications" whereby his electric light machine might be transferred into a motor, and Bradley is almost equally vague. Eminent electricians united in the view that by reason of reversals of direction and rapidity of alternations an alternating-current motor was impracticable, and the future belonged to the commutated continuous current.

It remained to the genius of Tesla to capture the unruly, unrestrained and hitherto opposing elements in the field of nature and art and to harness them to draw the machines of man. It was he who first showed how to transform the toy of Arago into an engine of power; the "laboratory experiment" of Baily into a practically successful motor; the indicator into a driver; he first conceived the idea that the very impediments of reversal in direction, the contradictions of alternations might be transformed into power-producing rotations, a whirling field of force.

What others looked upon as only invincible barriers, impassable currents and contradictory forces, he seized, and by harmonizing their directions utilized in practical motors in distant cities the power of Niagara.

A decree may be entered for an injunction and an accounting as to all the claims in suit.

DISCUSSION AND CORRESPONDENCE.

MR. TESLA AND THE UNIVERSE—HUMAN ENERGY AND HOW TO INCREASE IT—HIS PHILOSOPHIZING QUESTIONED.

MR. NIKOLA TESLA has written a long article in the *Century Magazine* for June with the title 'The problem of increasing human energy, with special reference to harnessing the sun's energy.' The paper is profusely illustrated with impressive cuts of electrical experiments which, at first sight, seem convincing. Most readers of the *Century* looked at the striking cuts and glanced at some of the head lines of the article such as 'Development of New Principle'; 'Production of Immense Electrical Movements'; 'The Earth responds to Man'; Interplanetary Communication now probable,' and accepted the headlines on the testimony of the cuts; or else took it frankly for granted that so long an article must certainly prove a great deal.

The present writer has lately gone over the text of the article, pen in hand, and herewith

presents a small portion of his notes. They seem to him to show that the article in question is composed, essentially, of three different kinds of writing. The first kind describes Mr. Tesla's experiments in electricity and shows what he has already accomplished. This work is, no doubt, important. Its value will be appraised by experts. The present writer has no claim to be considered an electrical expert and does not attempt to give an estimate of the achievements referred to. The second describes what Mr. Tesla expects to accomplish in the future. His prophecies are so sanguine, in many cases, that even a general reader may presume to compare them with the comparatively small things already accomplished and to point out how very unlikely it is that any great part of his expectations will be realized within any reasonable future—within Mr. Tesla's own lifetime, for example.

The third element of this article consists of philosophical arguments about things in general—about human life—what it is—the future of the solar system—the solidarity of the human race—the Christian religion—vegetable food—theoretical dynamics—athletics in colleges—drinking water—ozone—education of women—ice—fertilizers—insanity—warfare—flying machines—iron manufacture—aluminium—liquid air—self acting engines—the inhabitants of Mars—etc., etc., etc.

Now these and other matters are interesting in themselves. We are all anxious to obtain new light upon them. We are all more or less competent to judge the conclusions of other people regarding them. It is not too much to say that this portion of Mr. Tesla's paper is in the main so trivial, so superficial, so obviously weak, as to throw doubt upon the whole essay. Many of the subjects treated are the oldest problems of the human race. They have been discussed by every philosopher since Aristotle. It is fairly astonishing to see Mr. Tesla's reasonings in print at this day. They compare with the logic of giants like Spinoza, Kant, Lord Kelvin, Herbert Spencer, and the rest as a baby's prattle to the 'Summa Theologiæ.'

If this judgment seems too harsh the following paragraphs will fully confirm it. No discourtesy is meant to Mr. Tesla. But his paper has been printed. It now belongs to his readers. He must allow them to compare his philosophizing with that of his great predecessors and with the dicta of common sense.

The paper begins by asking profound questions with regard to human life. Whence comes it? What is it? Whither does it tend? "*Though we may never be able to comprehend human life, we know certainly that it is a movement, of whatever nature it may be,*" is Mr. Tesla's answer. A movement?—*one* movement? Are we sure it is a movement, and nothing else? "*Hence, wherever there is life, there is a mass moved by a force.*" A mass? A force? Why not masses, forces, hundreds of them? These beginnings which seem so definite lead to the conclusion that life is a *rhythm*, but this conclusion is at once dropped for the utterly antagonistic conception that man, mankind, is '*a mass urged on by a force.*' A force will urge a mass onward, not swing it rhythmically. We need not linger over this discrepancy, though there might be something to say, if it were worth while.

Mankind is then conceived as *one* physical mass; and Mr. Tesla's proof that this is a true conception is derived from the fact that every one of us feels sympathy with a friend who is hurt. Here is a mixing of two worlds—the world of matter and the world of feeling—which does not tend to clearness. The man born blind thought the sunset like a pleasing friendship. Swedenborg in his idea of the Grand Man who is the sum and integral of all individual men has put the question in a much truer light; but let us pass on. Man is, according to Mr. Tesla, '*a mass*,' one physical mass. Call this physical mass M. M is a quantity which can be expressed in tons or in ounces. Mankind is '*impelled in one direction*'—*one* direction!! by a force f, "*which is resisted by another force R, acting in a direction exactly opposite.*"

The idea in Mr. Tesla's mind is apparently that the force R is the reaction of the first force f. But every reaction is not only opposite to its action but equal to it, according to Newton. Not so in Mr. Tesla's universe. Reactions are opposite to, but less than actions. There is an effective force left over, which, in

his scheme, imparts a velocity V to mankind, M. "*Human energy will then be given* (measured) *by the product* $\frac{1}{2} MV^2$, *in which* M is the *total mass of man in the ordinary interpretation of the term 'mass,'* and V *is a certain hypothetical velocity which, in the present state of science, we are unable exactly to define and determine.*" How learned all this looks! and how foolish it all is! Mankind has a physical mass, no doubt. The *energy* of mankind is the sum of a million different energies, of very different *qualities* as well as of different amounts—spiritual as well as physical. These different energies, being of different kinds, cannot be expressed by a single term. Mr. Tesla's algebraic formula is mere solemn rubbish. It has absolutely no meaning.

There are three ways of increasing human energy, Mr. Tesla says: I. To increase the mass and energy of mankind more children must be born, fewer individuals must die, and the children must be of '*higher velocity*' than the parents (and *velocity* Mr. Tesla takes as exactly equivalent to *enlightenment*). Here Mr. Tesla pauses to discourage college athletics, and to say that although whisky, tea and tobacco shorten human life, yet he does not think that vigorous measures should be taken to suppress the habits of using them. On the contrary he would leave whisky alone, and improve the quality of drinking water. '*Gambling, business-rush, excitement * * * uncleanliness * * * laxity of morals * * * the society-life, modern education and the pursuits of women*' and other matters tend to diminish the mass of mankind, but want of food is the chief cause.

Cattle are food of '*low velocity*' (enlightenment) Mr. Tesla says, and he does not approve of raising cattle, therefore. '*It is certainly preferable to raise vegetables.*' Here he has forgotten his basic principle, unless, indeed, he is prepared to prove that turnips are food of 'high velocity,' *i. e.*, enlightenment. Here, again, as in the case of rhythmic motion, he no sooner lays down a principle than he abandons or neglects it for something quite different. However his vote is for vegetables, and more are wanted. To fertilize the soil more nitrogen is needed. He has an electric method for obtaining nitrogen from the atmosphere (so has Sir William Crookes) and the world's food supply is safe. All this is very well known. There is nothing new about it except the solemn manner in which it is said.

II. The second point is to reduce the force that retards the human mass. This force is a compound of ignorance, stupidity, imbecility, insanity, religious fanaticism, etc. It is not so simple then as Mr. Tesla's 'force R' with which he began. Warfare is a retarding force but Mr. Tesla thinks it will be with us for some time yet, and indulges in a short excursion on flying-machines. "*The flying-machine is certainly coming and very soon. I see no reason why a ruling power like Great Britain might not govern the air as well as the sea. I do not hesitate to say that the next years will see the establishment of an 'air-power,' and its center may not be far from New York*" (possibly in Mr. Tesla's laboratory?). After a couple of pages devoted to warfare, harbor-defense, flying-machines, foreign invasion, international agreements, eternal justice, prehistoric man and his weapons, Mr. Tesla concludes that future battles will be decided by matching one complicated machine (say British) against another (say Russian).

"*Machines will meet in a contest without bloodshed, the Nations being simply interested, ambitious spectators. When this happy condition is realized peace will be assured.*" "*Bloodshed,*" Mr. Tesla thinks, "*will ever keep up barbarous passions.*" Hence we must '*produce a machine capable of acting as though it were a part of a human being.*' Such a machine may be destroyed but no blood will flow. Mr. Tesla has not yet produced a machine of the sort but he means to do it.

He tells us that as a boy he noticed that whatever he thought of he saw. He visualized words in his mind. By attention he discovered that every occurrence in his mind was suggested by some previous outside occurrence or object. Hence, he was not a free agent, but played upon by his environment. He was the sport of the universe—an automaton. "*I have demonstrated, to my absolute satisfaction, that I am an automaton endowed with power of movement, which merely responds to external stimuli beating on its sense-organs, and thinks and acts and moves accordingly.*" He may be an automaton; but if he thinks that the foregoing argument proves

it, he is no logician. Being an automaton himself Mr. Tesla proceeded to make another automaton. He consented to make it full-grown to save time. It was also unnecessary to endow it with the power of propagating its kind, since Mr. Tesla himself could make more machines when he wanted them. He likewise consented to make it without a mind, because a mind '*I could easily embody in it by conveying to it my own intelligence.*'

With these slight differences from the Garden of Eden Mr. Tesla's workshop has turned out a kind of electrical boat or animated bath-tub (see the cut) whose movements can be controlled from a distance. This machine '*behaved just like a blindfolded person obeying directions received through the ear.*' It had a '*borrowed mind.*' In fact, it had no mind at all, except in Mr. Tesla's confused terminology. It had the same kind of a mind as a Waltham watch. It is now Mr. Tesla's intention to build an '*Automaton*' '*which will have its own mind.*' "*It will be capable of distinguishing between what it ought and what it ought not to do.*"

Of course, such words are merely quibbles. In exactly the same sense a steam-engine has its own mind, and distinguishes what it ought from what it ought not to do. So did Maelzel's mechanical duck. So did Babbage's calculating engine. So does every device. Either the words mean nothing new; or else they are deceptive quibbles. It does not mend matters to say: '*my ideas on this subject have been put forth with deep conviction, but in a humble spirit.*'

Universal peace will be realized, he says, "*when all darkness shall be dissipated by the light of science, when all nations shall be merged into one, and patriotism shall be identical with religion, when there shall be one language, one country, one end, then the dream will have become reality.*" To bring about these desirable conclusions, an automatic fighting machine is necessary. Mr. Tesla is now engaged on the question automatically.

III. But all this while the main point has been lost sight of in divagations. How to increase the forces moving the human mass is the question. For reasons not adduced Mr. Tesla declares that '*the resultant of all these forces is always in the direction of reason.*' Every individual man is an automaton, we have seen, and will act unreasonably if played upon by certain forces. But mankind, which is made up of men, always acts reasonably. 'Tis strange; one seems to recall instances from history that refute the assertion. And indeed, Mr. Tesla himself does not really believe it. What is this busy world, he asks, but 'an immense clock-work?' A 'reasonable' clock-work! He finds, finally that "*the great problem of increasing human energy is answered by the three words: Food, Peace, Work.*" "*These three words,*" he says "*sound the key-note of the Christian Religion.*" One had supposed that Faith, Hope and Charity were the key-notes of the Christian religion; and that this religion had no message at all to a world of automatic men.

With a touching little eulogy on iron, and the prediction that aluminum is soon to take its place, and a good word for coal and for gas-engines, he passes on to the question of obtaining energy direct from the sun, and discusses the "*possibility of a self-acting engine or machine, inanimate, yet capable, like a living being, of deriving energy from the medium.*" His conclusion is that it is possible though it cannot be produced for a long time yet. It is not pressing, then, to discuss his results. We will wait until some are forthcoming.

The next paragraphs of Mr. Tesla's long paper are taken up with the description of his experiments on electrical matters, wireless telegraphy (which Marconi independently discovered and has made practical), etc. Into these we will not follow him, except to say that he claims to be able to produce electrical effects on the planets Venus or Mars by methods which he is very careful not to explain. He expects an answer, too: "*That we can send a message to a planet is certain, that we can get an answer is probable; man is not the only being in the Infinite gifted with a mind.*"

We might go on page by page, pointing out error, extravagance and bathos like the preceding. There seems to be no special need to go further. It should be evident to any impartial reader that the value of Mr. Tesla's general philosophical speculations and opinions is exactly *nil*. The value of his work in elec-

tricity must be judged by experts. The weight of his predictions as to future discoveries would be greater if his judgment on things in general were less unsound. It is passing strange that such loose reasonings can find a publisher. It is to be hoped that they will gain little credence from his readers. A line from Plato's Republic applies here (changing a word) to wit: "I verily believe that it is a more venial offence to be the involuntary cause of death to a man than to deceive him concerning scientific truth."

Western Electrician

EVERY SATURDAY.

PUBLICATION OFFICES:
510 Marquette Building, - CHICAGO.
TELEPHONE, MAIN 1746.

Eastern Office, 148 Times Building, New York.

European Office, 44 Fleet Street, London, E. C.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the **old address** as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own.* THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

Mr. Tesla has made so many curious statements in relation to what he proposes to do that it is pleasing to note a generous recognition of the valuable work that he has actually accomplished. Such a tribute is paid in the recent opinion of Judge Townsend, upholding the rotating-field patents granted on Tesla's brilliant discovery. Through the daily and technical press this judicial decision has gained wide publicity and will serve to bring again to mind an important portion of Tesla's really beneficial work.

TESLA has so injured his prestige by premature and impracticable assertions that his announcements in the field of electrical discovery do not attract the attention they formerly commanded. His latest claim is to have successfully overcome the cause of electrolysis, and he has an invention designed to prevent the escape of electricity from a wire. He claims that he can insulate the wire by passing through it or near it air kept at a low temperature, producing a coat of ice on the wire which cannot be broken through by the strongest currents, and at the same time gives an insulation that costs practically nothing. By means of this the loss of electricity or electrical energy in transmission, it is claimed, can be rendered so small as to be insignificant, and power can be transmitted to great distances by means of underground wires. So far it is only a claim, but on a subject of surpassing interest to the electrical world.

Tesla Patents Sustained.—The suit of the Westinghouse Electric & Manufacturing Company against the New England Granite Company upon an infringement of the three Tesla polyphase power-transmission patents issued May 1, 1888, was recently decided in favor of the Westinghouse Company. The decision is a very sweeping one and is phrased in part in vigorous verbiage. Other parts of the decision appear unnecessarily oratorical; a notable paragraph of this character reads as follows: "It remained to the genius of Tesla to capture the unruly, unrestrained and hitherto opposing elements in the field of nature and art and to harness them to draw the machines of man. It was he who first showed how to transform the toy of Arago into an engine of power; the 'laboratory experiment' of Baily into a practically successful motor; the indicator into a driver; he first conceived the idea that the very impediments of reversal in direction, the contradictions of alternations might be transformed into power-producing rotations, a whirling field of force."

The Tesla Patents.—A decision, considered to be of some importance on the other side of the Atlantic, has been given in the United States Circuit Court of Connecticut with regard to the three Tesla patents, Nos. 381,963, 382,280 and 382,279 of May 1, 1888. The following were the claims at issue in the three patents :—

Patent No. 381,968.

1. The combination, with a motor containing separate or independent circuits on the armature or field magnet, or both, of an alternating-current

generator containing induced circuits connected independently to corresponding circuits in the motor, whereby a rotation of the generator produces a progressive shifting of the poles of the motor, as herein described.

3. The combination, with a motor having an annular or ring-shaped field magnet and a cylindrical or equivalent armature, and independent coils on the field magnet or armature, or both, of an alternating-current generator having correspondingly independent coils, and circuits including the generator coils and corresponding motor coils in such manner that the rotation of the generator causes a progressive shifting of the poles of the motor in the manner set forth.

Patent No. 382,280.

The method herein described of electrically transmitting power, which consists in producing a continuously-progressive shifting of the polarities of either or both elements (the armature or field magnets or magnets) of a motor by developing alternating currents in independent circuits, including the magnetising coils of either or both elements, as herein set forth,

Patent No. 382,279.

1. The combination, with a motor containing independent inducing or energising circuits and closed induced circuits, of an alternating-current generator having induced or generating circuits corresponding to and connected with the energising circuits of the motor, as set forth.

2. An electro-magnetic motor having its field magnets wound with independent coils and its armature with independent closed coils, in combination with a source of alternating currents connected to the field coils, and capable of progressively shifting the poles of the field magnet, as set forth.

3. A motor constructed with an annular field magnet wound with independent coils and a cylindrical or disc armature wound with closed coils, in combination with a source of alternating currents connected with the field-magnet coils, and acting to progresively shift or rotate the poles of the field as herein set forth.

The action was brought by the Westinghouse Electric and Manufacturing Co., the owners of the Tesla patents, against the New England Granite Co., and the judge declared that the patents were valid, and had been infringed.

DISCUSSION AND CORRESPONDENCE.

NEWSPAPER SCIENCE.

TO THE EDITOR OF SCIENCE: I have had so much satisfaction in the review and criticism recently published in SCIENCE, of Mr. Tesla's magazine article on 'Human Energy' that I cannot avoid making public acknowledgment of my appreciation of its justice and timeliness, especially the latter. Is it not the imperative duty of men of science to do what the author of this review has done, more frequently than they have during the past ten years?

Within this decade there has been an enormous decrease in the cost of publication and especially in the expense of illustration, and this has brought about a deluge of reading matter of such infinite variety and general worthlessness that the formation of a society for its systematic suppression is worthy of serious consideration. With the daily newspapers it has been distinctly an era of sensationalism.

A reporter for a daily paper recently de-

clared that he was required by his chief to 'furnish at least two sensations a week.' Nearly all the more respectable and conservative magazines have yielded somewhat to this demand. The general reading public has recognized in an indistinct and uncertain way that much that is wonderful in this 'wonderful century' is due to scientific discovery, and it is apparently hungry for easy exposition of scientific work. It seems to like, at any rate it is largely fed upon, science of the 'head-line' variety, and those who can furnish this sort are in great demand. Unfortunately there are a few men, fortunately not many, who have done and are doing really excellent scientific work who are ready to cater to this morbid appetite, and there are many others, merely 'hack' writers with neither knowledge or reputation, who find it easy to imitate them. The result tends to dull the scientific sense and corrupt the judgment of the great majority of readers. What we see in print concerning what we do not understand we almost invariably accept as true unless it violently opposes our prejudices or accepted theories, and the general public, therefore, is in a very receptive mood towards announcements of scientific discoveries and accomplishments. That this is taken advantage of to reach the purse of the public no one can deny, and it is impossible not to find certain very respectable and otherwise conservative journals largely responsible for losses of thousands of dollars by comparatively poor people through stock subscriptions in schemes believed to be backed by scientific men. It is no valid defense to say that the editors of these journals were imposed upon, for if they were they need not have been. Other journals, including some daily papers, know very well how to avoid such imposition and have the courage to do it. It appears to be accepted as a fundamental principle of what is called 'journalism' in these days that any one who is gifted with a little facility in writing, a far-reaching imagination and a conscience without elastic limit may be properly 'assigned' to prepare an article on any subject whatever, and thus we are treated to weekly or monthly essays by one author covering, in fact sometimes rather more than covering, in a few months the whole area of human knowledge. Perhaps they, too, have their orders to produce a given number of 'sensations' in a given time.

Among many other evils growing out of what may be called 'Newspaper Science' not the least is the manufacturing and maintaining of false reputations. The constant appearance of a name in connection with the development of a given art, science, discovery or invention makes an impression which it is difficult to destroy, and this is true even among the most intelligent classes. To find who is really and truly eminent in any field of human activity one must go to the specialists in that field. The popular verdict is more than likely to be wrong because it is based on fictitious, newspaper-created renown. Is there not, indeed, some danger that in spite of the carefully selected and altogether able jury, the newly created roll of American honor may, in certain cases and for the lack of this appeal to specialists, become a Hall of Notoriety rather than Fame? The selection of S. F. B. Morse for a place therein must have been due to the general belief among the jurors that he was the inventor of the electro-magnetic telegraph. Yet it was long since proved beyond dispute that his share in that invention was among the least of the many who contributed to make the telegraph possible, and that he justly deserves only a relatively very small share of the honor belonging thereto.

The New York Herald November 28, 1900

A "Wireless Telegraph" Rumor.

If what is said in the London *Express*—not by Marconi, but by an unnamed member of his staff—and is retold in our special cable is a foreshadowing of what the master of wireless telegraphy has succeeded—or is about to succeed—in doing, then Marconi has indeed made a marvellous stride beyond the point he had heretofore reached in his discoveries and inventions.

According to the *Express* story we shall soon have England and America in close communication without wires. Indeed, England and anywhere you like, if you can have a station there, can be in reach, for Marconi's staff member says in effect that his chief has 'discovered the secret he has long looked for and can annihilate the difficulties of distance and the earth's curvature.

All of which is of great importance and interest if Mr. Marconi confirms it.

The New York Herald December 30, 1900

NIKOLA TESLA Shows How MEN . . . . . of the Future May Become as GODS

BY NIKOLA TESLA.

WHEN a child is born, its sense organs are brought in contact with the outer world. The waves of sound, heat and light beat against its feeble body, its sensitive nerve fibres quiver, the muscles contract and relax in obedience—a gasp, a breath, and in this act a wonderful little engine, of inconceivable delicacy and complexity of structure, is hitched to the wheelwork of the universe. Left to itself the engine stops; it has no power to draw energy from Nature's inexhaustible store.

The little engine moves and works, changes size and shape, performs more and more varied operations, becomes sensitive to more and more different influences, and now there begins to manifest itself in it a mysterious force. It becomes capable of responding to stimuli of a more subtile nature and of drawing, for its own use, energy from the environment. Gradually the engine has been transformed into a being possessed of intelligence, which perceives, discerns, does like others of its kind.

The experiences multiply, the knowledge increases, the discernment becomes keener, the human being, responding to the faintest influences, is awakened to the consciousness of Nature and its grandeur, and in its breast there is kindled a desire to imitate Nature, to create, to work itself the wonders it perceives.

But the exercise of this power does not satisfy the mind, which rises to still higher, undefinable perceptions, not of this world, and inspired by them the artist, the inventor and the man of science give expression to the longing of the soul.

What can man, with his power of creating, in his striving toward the ideal, produce; what result can he attain which would be of the greatest consequence in this universe, his greatest achievment? A scientific idea which I advanced nearly two years ago in an unpublished address may serve to answer this question, from a point of view likely to be taken by an inventor or engineer.

According to the adopted theory, first clearly formulated by Lord Kelvin, all matter is composed of a primary substance of inconceivable tenuity, vaguely designated by the word "ether." The atom of an elementary body is differentiated from the rest of this substance, which fills all space, merely by movement, as a small whirl of water would be in a calm lake.

All matter, then, is merely whirling ether. By being set in movement, ether becomes matter perceptible to our senses; the movement arrested, the primary substance reverts to its normal state and becomes imperceptible. If this theory of the constitution of matter is not merely a beautiful conception, which in its essence is contained in the old philosophy of the Vedas, but a physical truth, then, if the ether whirl or atom be shattered by impact or slowed down and arrested by cold, any material, whatever it be, would vanish into seeming nothingness, and, conversely, if the ether be set in movement by some force, matter would again form. **Thus, by the help of a refrigerating machine or other means for arresting ether movement and an electrical or other force of great intensity for forming ether whirls, it appears possible for man to annihilate or to create at his will all we are able to perceive by our tactile sense.**

This conclusion, though startling, is not contradictory to the adopted doctrine of the indestructibility of matter, and in the light of modern views it may be considered as a scientific possibility. It does not require the exercise of great powers of imagination to conceive that by harnessing the sun's energy and making his machines self-acting these processes of creation and annihilation might be made to go on without human intervention other than the control.

Could he do this, man would then have god-like power, for he could create any kind of material substance, of any size and shape, seemingly out of nothing, and he could make all perceptible substance revert to its primary form, lose itself forever in the universe.

At his command, almost without an effort on his part, worlds would disappear and new worlds would be born. This, according to my ideas, would be the grandest feat which might be performed by man, the most consequential, his greatest achievement.

The New York Journal And Advertizer January 1, 1901

ASTRONOMERS NOW TALK OF SIGNALLING PLANET MARS.

HAS NIKOLA TESLA SPOKEN WITH MARS?

Chicago, Dec. 31.—Nikola Tesla, the great electrician, writes:

The retrospect is glorious, the prospect is inspiring; much might be said of both

But one idea dominates my mind. This—my best, my dearest—is for your noble cause. I have observed electrical actions which have appeared inexplicable, faint and uncertain though they were, and they have given me a deep conviction and foreknowledge that ere long all human beings on this globe, as one, will turn the eyes on the firmament above with feelings sof love and reverence, thrilled by the glad news:

"Brethren, we have a message from another world, unknown and remote. It reads: ONE—TWO—THREE."

(Signed) NIKOLA TESLA.

Several months ago Nikola Tesla made a journey to Colorado. He went up among the mountains, away from human habitation. There he made many experiments. His pet dream for years has been to ascertain if the planets are inhabited. Is it possible that in some mysterious way this electrical wizard has received a message from Mars?

TESLA'S CALL FROM MARS?

SOME PLANET, IT SEEMED TO HIM, AFFECTED HIS MACHINE.

Suggestive of Signalling, the Movements Recorded When He Was Noting Electrical Conditions on a Peak in Colorado—Why Shouldn't Mars Know Morse as Well as We?

Not quite two years ago Mr. Nikola Tesla went out to Colorado to conduct experiments in relation to the wireless transmission of energy, which has engaged his attention for several years. Mr. Tesla found it necessary, in order to carry on his investigations and his experiments to the extent he desired, to work at an altitude of several thousand feet. He found conditions suitable for his purposes in Colorado and went out there in the spring of 1899, built a laboratory about ten miles from Pike's Peak and went to work. What he accomplished in the eight or nine months while he was working there he has kept pretty well to himself, but [illegible] when the National Red Cross, which was arranging for the end of the century meetings of its various branches throughout the country, asked Mr. Tesla to indicate what, in his opinion, would be one of the most striking achievements of the coming century, he gave just a hint of one of the wonders he discovered in Colorado.

In a more elaborate way Mr. Tesla dwelt on his work to a SUN man yesterday afternoon. He regards his latest results as far and away the most important he has ever attained. Briefly, Tesla has been able to note a novel manifestation of energy, which he knows is not of solar or terrestrial origin, and, being neither, he concludes that it must emanate from one of the planets. While he was conducting his investigations in his Colorado laboratory one day the instrument he was using to observe the electrical condition of the earth was affected in an unaccountable manner. It recorded three distinct, though very faint movements, one after the other. These movements were observed not once, but many times, the number of impulses varying, and Mr. Tesla now firmly believes that, with improved apparatus, it will be quite possible for the people of the earth to communicate with the inhabitants of other planets. In talking about his work and his discoveries Mr. Tesla said:

"I went to Colorado early in May, 1899, and stayed there about eight months. I believe that during this time I did more work than I could have done in the city in three years on account of the marvellously invigorating climate. I was compelled to go either to Colorado or to California, as only in these two States could I obtain power at a high altitude, which was necessary for certain investigations I had in view relative to the transmission of power in accordance with a method I had invented. I had tested the conditions at sea level thoroughly, and wanted to know in how far my laboratory observations would agree with practical tests at high altitudes. Colorado was nearer than California and I had some friendly relations in Colorado Springs, and this determined me to select that neighborhood for my place of observation.

"A laboratory was erected on an elevation at a distance of about ten miles from Pike's Peak. I set out to carry on my experiments along three different lines: First, to ascertain the best conditions for transmitting power without wires; second, to develop apparatus for the transmission of messages across the Atlantic and Pacific oceans, on which problem I have been engaged for eight years, and, third, to work on another problem, which involves a still greater mastery of electrical forces and which, with my present knowledge, I consider of still greater importance than even the transmission of power without wires, and which I shall make known in due course. There were, however, numerous points to be found out about electrical vibrations, and there were actions on which I was still in doubt. In my laboratory in New York I was able to go only to electrical discharges of 16 feet in length and I had only reached effective electrical pressures of about 8,000,000 volts. To carry the problems on which I was working farther I had to master electrical pressures of at least 50,000,000 volts, and electrical discharges were necessary for some purposes measuring at least fifty or one hundred feet.

"The results I attained were far beyond any I had expected to reach, and this has forcibly brought to my mind the stimulating influence of nature in scientific research. I found that my mental vision was incomparably clearer, so much so that I could look back in thought to my laboratory in New York, and in examining familiar objects in the rooms there could notice the smallest scratches on them, and in examining the features of my assistants I could notice the slightest marks on their faces, as though they had been actually before me. Now in the city the mental images are much dimler.

"One of the first observations I made in Colorado was of great scientific importance and confirmatory of a result I had already obtained in New York. I refer to my discovery of the stationary electrical waves in the earth. The significance of this phenomenon has not yet been grasped by technical men, but it virtually amounts to a positive proof that, with proper apparatus, such as I have perfected, a wireless transmission of signals to any point on the globe is practicable. When I read statements to the effect that such a thing is impossible, and recall the numerous adverse comments of my expressed confidence that I can ultimately accomplish this, I experience a feeling of satisfaction.

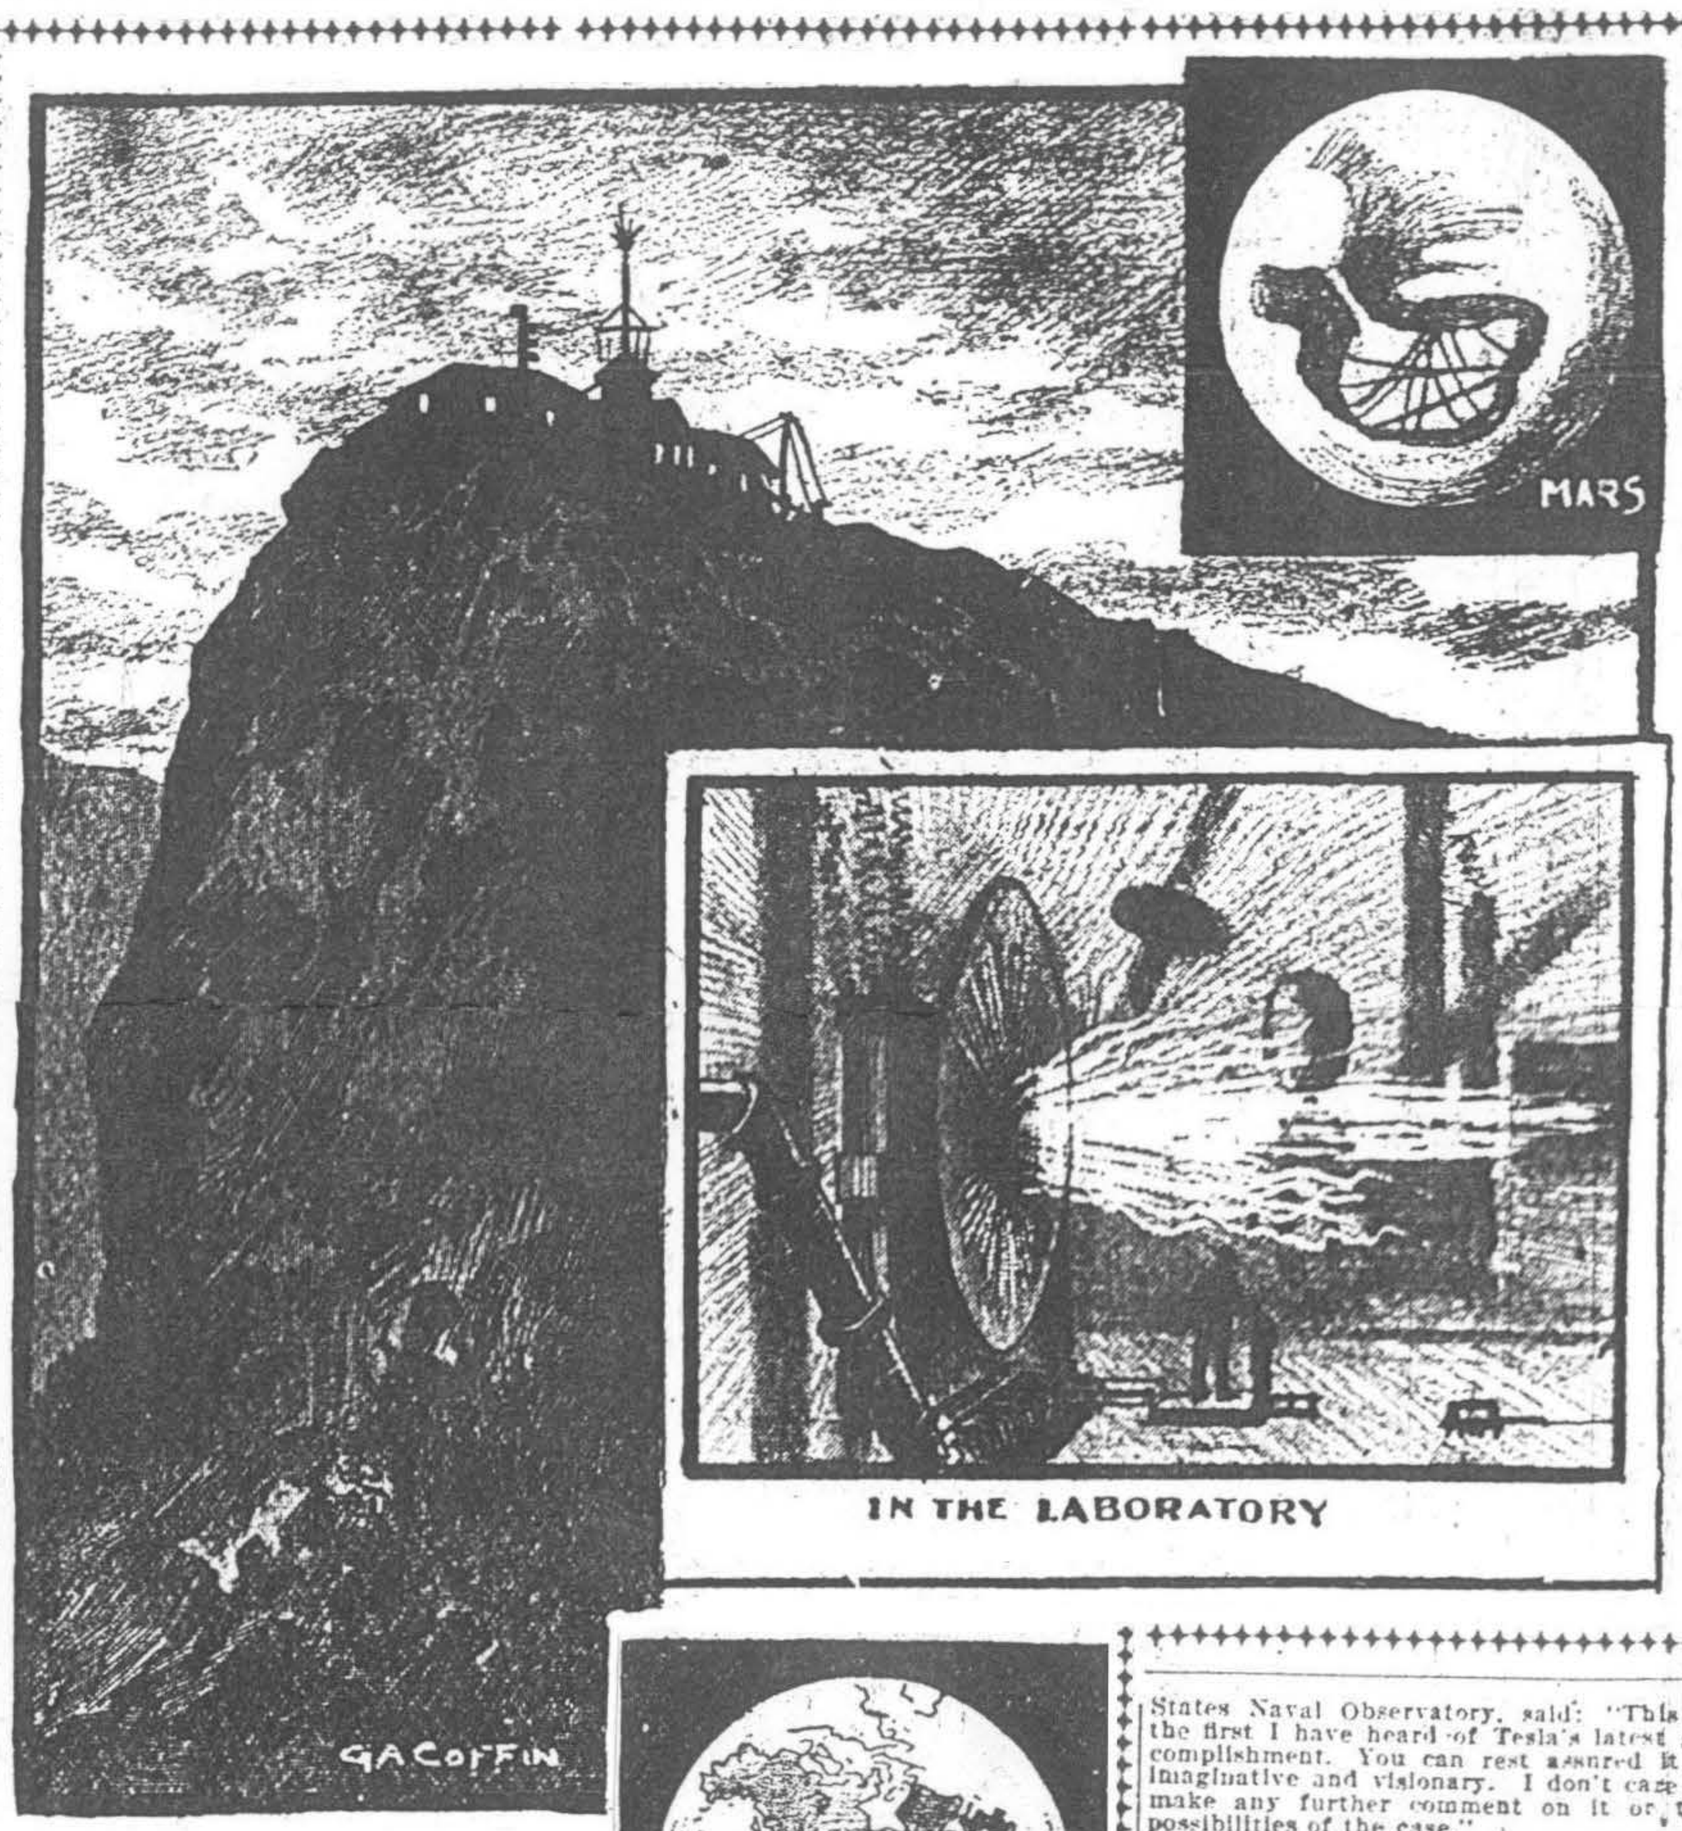
"In perfecting my apparatus I encountered at first great difficulties. I had to fence narrow escapes from sudden sparks jumping out to great distance, and a number of times my laboratory caught fire, but I carried all the work through without a serious mishap. I gradually learned how to confine electrical currents of a pressure of 50,000,000 volts; how to produce electrical movements up to 110,000 horsepower and I succeeded in obtaining electrical discharges measuring from end to end 100 feet and more. These results were, however, rendered more valuable by the fact that they opened up still greater possibilities for the future.

"Parallel with the development of my machinery for the production of powerful effects I also perfected novel methods for detecting feeble electrical actions, which, I feel confident, will be important in a number of lines of scientific research. To illustrate the efficacy of these methods I need only say that, whereas in ordinary, finely adjusted Hertzian appliances a lightning disturbance could be detected at a distance of only 300 miles, with my methods it was easy to observe the effect in the receiving instrument at a distance of 1,100 miles. It was, in fact, in investigating feeble electrical actions transmitted through the earth that I made some observations which are to me the most gratifying. Chief among these were certain feeble electrical disturbances, which I could barely note at times and which by their character unmistakably showed that they were neither of solar origin nor produced by any causes known to me on the globe.

"What could they be? I have incessantly thought of this for months until finally I arrived at the conviction, amounting to almost knowledge, that they must be of planetary origin. As I think over it now it seems to me that only men absolutely stricken with blindness, insensible to the greatness of nature, can hold that this planet is the only one inhabited by intelligent beings. I have perfected my transmitting apparatus so far that I can undertake to construct a machine which will without the slightest doubt be fully competent to convey sufficient energy to the planet Mars to operate one of these delicate appliances which we are now using here, as, for instance, a very sensitive telegraph or telephone instrument. Now since we ourselves are already so far advanced is it unreasonable to at least believe in the possibility that of the twenty or twenty-five planets of the solar system one, if not more, might be ahead of us in the evolution? Where there is sun's heat and moisture, life must originate and must go on developing just as a stone must fall to earth.

"I would have abstained from making the observations known for some time yet, had I not been asked by the Red Cross Society to give a short expression of opinion for their meetings on New Year's Eve. I have entertained a profound respect for the Red Cross ever since my boyhood, when I was told that the mere appearance of this society in the Balkans has advanced those wild regions a hundred years. I believe it to be the noblest and worthiest association in existence, and there was nothing which I could have refused to them, and furthermore I desired to give them my best. This discovery, in my opinion, was my best. With improved means of investigation we shall soon be able to find out whether indeed these disturbances which I have noticed are what I feel they must be. The time has certainly arrived for the electrician to join the astronomer in the exploration of our neighboring worlds.

"With regard to my work in other lines which I have simultaneously carried on, my progress has been most satisfactory, and I hope that soon electrical energy may be turned to the uses of man in a way and for purposes such as to surpass in importance all that we have ever done heretofore. The difficulties are still enormous, to be sure, but not such that we could not look with confidence to overcoming them. What will retard progress unquestionably is the fact that the mastery of electrical vibrations requires, like other arts, not only a thorough technical knowledge but years of continuous performance. Our colleges are rapidly turning out skilled and talented young men, and, whatever remains undone by us will be carried further by them."



The New York Journal And Advertiser January 4, 1901

ASTRONOMERS DISCUSS TESLA'S ALLEGED MESSAGE FROM MARS.

They View Incredulously the Wizard's Claim That He Has Received Signals from Other Planet.

Inventor Says HE Can Construct Instrument That Will Establish Interplanet Communication.

Many Scientists Advance Arguments to Substantiate Their Skepticism of Tesla's Assertions.

NICOLA TESLA claims to have had the first call of the century from a neighboring planet.

He has communicated with Mars, he declares, while on Pike's Peak, delving into the mysteries of the wireless transmission of electrical energy.

The summons was faint, but, according to Tesla, not to be mistaken.

A new voice, from a planet thousands of miles removed, was speaking over one of the myriad unwired telephones of the Universe, and there, near the lonely mountain peak, in the fathomless calm of night, the voice at last found a listener and world spoke to world in language strange at first, but sure to be clearer, says Tesla, ere the twentieth century has finished its course. Here the Journal presents what Tesla himself says of this first manifestation:

"It was in investigating feeble electrical actions transmitted through the earth that I made some observations which are to me the most gratifying.

"Chief among these were certain feeble electrical disturbances which I could barely note at times, and which by their character unmistakably showed that they were neither of solar origin nor produced by any causes known to me on the globe. What could they be?

Will Talk to Mars.

"I have incessantly thought of this for months, until finally I arrived at the conviction, amounting almost to knowledge, that they must be of planetary origin. I have perfected my transmitting apparatus so far that I can construct a machine which will without the slightest doubt be fully competent **to convey sufficient energy to the planet Mars to operate one of these delicate appliances which we are now using here, as for instance a very sensitive telegraph or telephone instrument.**

"Now since we ourselves are already so far advanced, is it unreasonable to believe that of the twenty or twenty-five planets of the solar system one, if not more, might be ahead of us in the evolution? Where there is sun's heat and moisture life must originate and must go on developing just as a stone must fall to earth."

Tesla's almost incredible discovery was made by him in Colorado two years ago while he was conducting experiments in relation to the wireless transmission of energy. He worked in a laboratory specially constructed about ten miles from Pike's Peak.

When he was asked yesterday to give some visible form or notation to the message he had received he smiled enigmatically and said:

"As I have already said, one of the planets in the solar system may be ahead of us in the evolution. Their means of interplanetary communication may be perfect, **but we have yet to learn their sign language.** It is impossible at present, even to suggest a code and my observations to the Red Cross Society on New Year's Eve were purely speculative, but for purposes of illustration they will answer the purpose at present.

It is enough to say at this time that a message from Mars which might be a triangle to them would appear as some other form to us and vice-versa. These differences can only be reconciled by time and careful study. It is wonderful enough, is it not, that a beginning has been made.

"On Pike's Peak I set out to carry on my experiments along three different lines.

"One of the first observations I made in Colorado was of great scientific importance and confirmatory of a result I had already obtained in New York. I refer to my discovery of the stationary electrical waves in the earth. The significance of this phenomenon has not yet been grasped by technical men, but it virtually amounts to **a positive proof that, with proper apparatus, such as I have perfected, a wireless transmission of signals to any point on the globe is practicable.** When I read statements to the effect that such a thing is impossible, and recall the numerous adverse criticisms of my expressed confidence that I can ultimately accomplish this, I experience a feeling of satisfaction.

Difficulties Encountered.

"In perfecting my apparatus I encountered at first great difficulties. I had a few narrow escapes from sudden sparks jumping out to great distance, and a number of times my laboratory caught fire, but I carried all the work through without a serious mishap. I gradually learned how to confine electrical currents of a pressure of 50,000,000 volts; how to produce electrical movements up to 110,000 horse-power and I succeeded in obtaining electrical discharges measuring from end to end 100 feet and more. These results were, however, rendered more valuable by the fact that they opened up still greater possibilities for the future.

"As I think over it now it seems to me, that only men absolutely stricken with blindness, insensible to the greatness of nature, can hold that this planet is the only one inhabited by intelligent beings."

As to the practical details of establishing a system of inter-planetary communication, Mr. Tesla is not yet prepared to talk. **His suggestion, however, of an interchange of mathematical forms would indicate at once a practical basis of operations** by means of initiating electrical disturbances at the three angles of a vast triangle described over an immense area of the earth's surface.

Observers at these points with means at command for the transmission of powerful electrical energy could thus indicate to the inhabitants of Mars in unmistakable manner the species of form language in which it was desired to hold communication.

Thus, little by little, an intelligible code could be established containing possibilities for the acquisition of exact data concerning other worlds far beyond the wildest dreams of necromancers.

Tesla now firmly believes that with improved apparatus it is not only probable, but entirely possible; that we shall be able to communicate with the inhabitants of other planets.

The Pike's Peak Laboratory.

It was while working in this laboratory experimenting to perfect instruments for wireless telegraphy that Tesla claims to have observed the manifestations which, he asserts, were telegraphic signals from some other planet, presumably Mars.

ASTRONOMERS VOICE SCEPTICAL VIEWS.

Discuss with Considerable Incredulity the Story of Mr. Tesla's Alleged Discovery.

Washington, Jan. 3.—Professor S. I. Brown, of the United States Naval Observatory, said to-day: "Any proclamation coming from Tesla is likely to be received with considerable incredulity. I have been looking in vain for some practicable results to follow the extravagant claims that he has constantly made during the past half dozen years.

"His assertion that he has found that some planet is signalling to the earth is remote even to the point of impossibility. He contradicts himself so frequently that it is hard to tell what he really means.

"He indicates that Mars might be the world which is attempting to communicate with us. It is most peculiar that any discovery involving Mars should be made just now. Once in every fifteen years that planet reaches its greatest distance from the earth, when it is 62,000,000 miles away. The nearest that it ever gets is 36,000,000 miles. It happens that just now Mars is at the furthest distance that it ever gets from us.

"Tesla indicates that this method of communication is based upon wireless telegraphy. The power of the electric wave vibrations involved in wireless telegraphy is inversely as the square of the distance they have traversed. Thus the electrical power required on the planet Mars in order to communicate with this world would be 3,600,000,000,000,000 times as great as the power received here. Even the faintest sign of energy that might be received here, when multiplied by that sum, would represent an incredible force on the surface of the planet Mars."

Professor A. S. Skinner, of the United States Naval Observatory, said: "This is the first I have heard of Tesla's latest accomplishment. You can rest assured it is imaginative and visionary. I don't care to make any further comment on it or the possibilities of the case."

Father John B. Hagan, Professor of Astronomy at the Georgetown University, said: "Astronomers do not look forward to the discovery of communication between the planets, and in fact, take no interest in and pay no attention to experiments of this character. There is, of course, no internal contradiction to the problem, being only a question of means on our side and the possibility of inhabitants in Mars. I would prefer not to make any comment on this particular alleged discovery of Tesla."

Professor T. J. J. See, of the Naval Observatory, said: "I have read the story about this discovery. I do not care to say anything about it."

MAGNETISM, MAYBE, SAYS SCIENTIST.

Professor Hough, of Chicago, Gives Possible Explanation of Tesla's Phenomenon.

Chicago, Jan. 3.—Professor George W. Hough, director of the Dearborn Observatory and teacher of astronomy at Northwestern University, said: "Tesla asserts that his instrument was disturbed, and that he is positive that the disturbance was not caused by the sun, moon or earth, and then concludes that it comes from Mars or Venus. A dynamo when running will show a disturbance on any magnetic instrument located a block away, depending on the power of the dynamo. It is probably some such magnetic cause that produces the peculiar effect on the oscillator spoken of by Tesla.

"This idea of communicating with the planets is an old one. More than a half century ago Thomas Dick, an English philosopher, wrote a book called 'Celestial Scenery,' in which this theory is discussed thoroughly. I am convinced nothing new has been discovered on the subject up to the present time."

John H. Kedzie, author of "Solar Heat, Gravitation and Sun Spots," said: "The theory is utterly visionary and impossible. Tesla is a great genius, but is not recognized by scientific men as a safe authority on scientific subjects. When he presents something he can prove to be true, scientific men will be quick to give him the credit due. The nearest point to the earth which the planet Mars ever reaches is 40,000,000 miles. The making of an instrument sensitive enough to record waves at this distance is beyond the range of human possibilities."

Twenty-Five Great Names in Electrical Science and Invention During the Nineteenth Century.

The lists which appear on the opposite page were compiled from individual lists received in response to invitations sent to the membership of the American Institute of Electrical Engineers for an expression of opinion as to what names connected with electrical science and invention during the century just closed, should appear on a list of twenty-five greatest names; and an indication by numerals of the names which, in their opinion, should be assigned first, second and third rank, respectively.

In response to this invitation 277 ballots were received and from these the general list on the opposite page was compiled. In order that an interesting comparison might be made with the general list, the two other lists printed with it were compiled as follows: From the 277 ballots those of twenty-five professors of electrical engineering were selected; also twenty-five ballots signed by leaders in various branches of electrical application and others whose opinions were thought to have particular weight. From these two sets of selected ballots the comparative lists, "A" and "B" were prepared.

The closeness of the vote of the first thirty names on the tally sheets was quite remarkable; in a number of cases the vote was a tie and this is indicated on the lists by braces opposite the names. On the general list tally sheet there was a difference of but seven votes between the twenty-fifth and the thirty-first names, and had the list been extended to the latter number it would have included the following names in the order given: Weston, Hopkinson, S. P. Thompson, Weber, Ferraris and Gray. Similarly, the tally sheet of the ballots cast by twenty-five professors of electrical engineering, if extended to thirty names, would have included Gauss, Wheatstone, Ewing, Röntgen and Rowland, the three last mentioned having but three votes less than the twenty-fifth on the list. Had the selected engineers' list been extended to thirty names it would have included Hopkinson, Marconi, Heaviside, Pacinotti and Steinmetz—the difference between the vote of the last mentioned and number twenty-five on the list being also three.

FARADAY

MAXWELL

KELVIN

EDISON

On the general list, there were practically but seven selections for the first, second and third places, and in the following order: Faraday, Kelvin, Edison, Maxwell, Henry, Morse and Bell. Faraday received almost twice as many votes as any of the others, and the vote of the next three names was largely in excess of the final three. On the professors' tally sheet, Henry stood fourth, the other names below his receiving but a few votes each. On the engineers' list. Edison was fourth, the subsequent names also receiving but a few votes each.

The name Siemens should be accepted as standing for the family rather than for any particular member thereof.

Result of Vote Upon Twenty-five Greatest Names in Electrical Science and Invention During the Nineteenth Century

A New Century Call-Up from Mars.

It will be remembered that Mr. Nikola Tesla has for some time past insisted on the possibility of exchanging signals with Mars, as determined by the results of his interesting experiments on wireless transmission. The New York *Sun* publishes on Jan. 3 a column interview with him on the subject and in it asserts that he has recently seen some curious effects on his apparatus. We quote as follows: "When the National Red Cross, which was arranging for the end try, asked Mr. Tesla to indicate what, in his opinion, would be one of the century meetings of its various branches throughout the countransmission. The New York *Sun* publishes this week a column inof the great achievements of the coming century, he gave just a hint of one of the wonders he discovered in Colorado. In a more elaborate way Mr. Tesla dwelt on his work to a *Sun* man. He regards his latest results as far and away the most important he has ever attained. Briefly, Tesla has been able to note a novel manifestation of energy, which he knows is not of solar or terrestrial origin, and, being neither, he concludes that it must emanate from one of the planets. While he was conducting his investigations in his Colorado laboratory one day the instrument he was using to observe the electrical condition of the earth was affected in an unaccountable manner. It recorded three distinct, though very faint movements, one after the other. These movements were observed not once, but many times, the number of impulses varying, and Mr. Tesla now firmly believes that, with improved apparatus, it will be quite possible for the people of the earth to communicate with the inhabitants of other planets."

CURRENT NEWS AND NOTES.

TESLAIC TELEGRAPHY.—A special dispatch from Washington, of Dec. 29, says: "Nikola Tesla has been asked by Rear Admiral R. B. Bradford, Chief of the Bureau of Equipment, to submit for trial a wireless telegraphy system perfected by him. Mr. Tesla says that his system is equal to, and perhaps superior to that of Marconi, and has offered to install it on naval vessels. Admiral Bradford in his last annual report recommended that negotiations be entered into with Marconi to secure his system for American vessels of war, if a reasonable rate could be agreed on."

The New York Herald January 5, 1901

DISCREDITS TESLA'S MARTIAN THEORY

Mr. Marconi Attributes Alleged Messages from Mars to Local Atmospheric Disturbances.

[SPECIAL CABLE TO THE HERALD.]

The HERALD'S European edition publishes the following from its correspondent:—

LONDON, Saturday.—Nikola Tesla having set up the fascinating, or fantastic, theory as to the possibility of communicating with the people of Mars, the Daily Mail yesterday sought the opinion of Mr. Marconi, who is conducting experiments in wireless telegraphy near Poole, and Mr. Marconi gave the following reply:—

"In earlier experiments, before my apparatus was perfected, I often received signals apparently from nowhere. This was undoubtedly due to atmospheric electricity. One of the greatest difficulties has been to produce an apparatus which would eliminate them, but this I have lately succeeded in doing.

"I should attribute the alleged signals from Mars to local disturbances in the atmosphere."

Professor Fleming, F. R. S., of University College, laughed at the idea of communicating with Mars, even if there are any people there.

"Is this idea taken seriously?" was his first question. "I am afraid," added the distinguished authority on electrical science, "that Tesla has been led away by his own imagination. It is difficult, of course, to say that anything is beyond the ultimate reach of science, but at present I should say that the people of Mars are."

Tesla's Twentieth-Century Views.

Since, in 1887, Mr. Tesla conceived and applied the rotating magnetic field to alternating-current power transmission, this remarkable man has received a large share of public attention. He possesses what has been termed a "scientific imagination," and his bold views of natural phenomena have been given wide publicity. The subjoined interview was obtained exclusively for the Western Electrician by Mr. Frank L. Perry and was telegraphed to Chicago at the last moment for insertion in the Twentieth Century issue.

Nikola Tesla was seen at the Waldorf-Astoria in New York late on Friday evening, January 4th. He consented to answer one pertinent question relating to his researches, and his reply indicates a perfect confidence that astonishing, but, nevertheless, practical, results will be achieved during the earlier part of the twentieth century, through the skilful utilization of electric "tuning" or resonance effects, with circuits carrying oscillating currents of high frequency.

The question put to Mr. Tesla was this: "From your own investigations with high-frequency currents and the transmission of electrical energy through their aid, as revealed by you to date, it would seem that there was a great future along this line. Therefore, will you not tell me, Does not the question of syntony, or, as the layman would put it, 'electrical tuning,' of circuits become a most important one, and one that indicates the direction investigations must take during, say, the next 10 or 15 years? Will not the greatest progress be made with what could very properly be called 'resonance effects?'"

"You have put a question," answered Mr. Tesla, "which not only is of great importance in many arts of the present day, but also throughout the mechanism of the universe. The phenomena of sound and light afford striking examples. I believe that ultimately even nerve action will be proved to involve the principles of 'sympathetic response.' Spencer's idea of the unstable nerve matter is ingenious in its conception, but difficult to be admitted as a reality. The cones of the retina, with their fibers, must likewise behave as elastic systems, responding sympathetically. If this be so, the undulatory theory can hardly be true, because the periods of oscillation of these vibratory systems would be far too great for those of the light waves. Nor can we stop at the simple nerve action, for, in the entire complex movement of humanity, the same universal principle forces itself upon our observation as unmistakably as in the vibrations of a tuning fork.

"My own experiments in electrical and mechanical vibration have impressed me deeply with the tremendous possibilities in this direction. With a small engine capable of pressing a piston back and forth with a force of but two pounds, I have set an entire block of modern buildings, by careful attunement, into such a violent swaying that people rushed out affrighted. With an impressed force of only a fraction of a pound, I have caused steel rings of several square inches cross-section, capable of supporting several hundred tons, to vibrate and form loops like thin piano wires, until they finally broke.

"In electrical vibration I have frequently obtained results even more wonderful. The tuning of electric circuits is becoming more and more important with the advancement of the arts and refinement of methods. The layman can have but a vague idea of what can be accomplished in this line by men possessed of knowledge and skill. As to the former, it is acquired easily enough. The principles are very simple and do not require an exceptionally high scientific training. Perhaps the clearest expositions have been given by Dr. Oliver Lodge and Prof. Pupin. The latter, particularly, was fortunate in dealing with the subject, and a beginner can find no better source of information.

"But the skill is not acquired as quickly or as easily as the knowledge of the simple principles. It comes slowly, requires great patience and untiring application. Owing to this fact, of necessity but few are proficient in this art to-day. This is the reason why the greater part of contemporaneous literature on this subject is pervaded with the grossest errors. Many experimenters do not seem to realize that an electrical system cannot vibrate through an imperfect contact or path of high resistance. Still many more overlook the necessity of placing the excited system in a condition permitting free oscillation, yet everybody knows that if he grips a spring firmly and pushes it back and forth it cannot perform its own vibrations. Similarly, an excited electrical system, as the secondary of a transformer, cannot oscillate freely if the exciting primary circuit is linked closely with it.

"While the establishment of the best relations between the physical constants of electric circuits is imposed by economy, yet the chief object will be the attainment of specific results, as, for instance, a very high electromotive force, a current of great intensity or the magnification of feeble impulses. The transmission of electrical energy through the earth, for whatever purpose it may be, offers, in my opinion, the greatest possibilities of development.

"The time is not far off when electrical oscillations will speed in all directions through the globe, innumerable, yet each separate and distinct and each fulfilling its mission. The seemingly simple subject expands as one advances in its study, until he feels as if the wide ocean were opening up before his eyes. Some five years ago, to test the capacities of a system of telegraphy, I 'tuned' repeatedly 150 circuits, calling up each one in turn, without disturbing the others. And I thought then I had mastered the art. As I look back on those experiences now I realize that I was then only just beginning to learn."

The New York Herald January 6, 1901

TESLA CONFIDENT OF SPEAKING MARS

Impossible, He Says, for Other Experimenters to Note Effects Which He Has Discovered.

HAVE NOT PROPER DEVICES

Inventor Says with His Appliances He Can Observe Electrical Condition of 2,200 Miles.

NO DOUBT OF FINAL SUCCESS

Nikola Tesla in his recent experiments in atmospheric electricity obtained results which he believes will make possible communication with the people of Mars. Scientific investigators abroad were sceptical as to his new theory. Professor Fleming, F. R. S., of University College, London, laughed outright at the idea. Mr. Marconi, who is experimenting in wireless telegraphy near Poole, attributed the alleged signals from Mars to local disturbances in the atmosphere.

Following is Mr. Tesla's reply to his critics and his explanation of his theory:—

"Having no exact knowledge of the means of investigation used by other experimenters, I cannot judge of the value of their observations. I assume that the same circuit arrangements and devices have been employed which are described in patents and articles on Hertzian telegraphy. In these cases an aerial conductor, not directly connected with the ground, but separated from it by imperfect contacts or coils which prevent the passage of the current, receives the effects transmitted from a distance.

"The atmospheric disturbances in these arrangements, if I am to judge from my own experience, are so great that I have always doubted their practical value. In my investigations these disturbing atmospheric influences were almost wholly excluded. It would have been impossible for other experimenters to note the effects which I have discovered, for with the Hertzian devices only a very narrow region can be explored, whereas I was able to observe the electrical condition of a large portion of the globe, a stretch of land 2,200 miles in width and breadth. That these actions are due to causes heretofore unknown I am convinced.

"I feel that I have not been led away by my imagination, but that my sight was true as ever before, and I am confident that future investigation will confirm my statement

"Nor have I the slightest doubt, judging from my experiments and measurements, that with a properly constructed electrical oscillator an amount of energy can be transmitted to a planet, as Venus or Mars, even at their greatest distance, sufficient to bring into action a sensitive instrument, such as I have been using in my own observations.

"Furthermore, it is an error to believe that a great expenditure of power is necessary for interplanetary communication. What is needed is an effect specifically great—an enormous rate of energy delivery, but lasting each time only a fraction of a second, so that the total power used up is small. Now, with my oscillator I can make this rate equal to five million horse power and more, if necessary, and my calculations show that a small fraction of this rate is amply sufficient for conveying a message to Mars.

"Heretofore light was the only known agent for communicating with a planet. It is easy to show that by its means such a result is virtually impossible, owing to the rapid diminution of energy with the distance and the impossibility of concentrating in an instrument the energy falling upon a large area. By the method and machinery I have devised we are enabled to convey an immeasurably greater amount of energy to the planet, and the observer there, instead of utilizing in his instrument only an infinitesimal amount of the entire energy conveyed, can avail himself of a large portion of the same.

"A practical solution has thus been found both for transmitting and receiving messages, and we can only hope that there are beings as far advanced, and possibly further than we are ourselves. I see no harm in holding fast to this possibility. This thought cannot but make us better and give us a fresh interest in life."

COLORADO SPRINGS GAZETTE

Published Every Day in the Year

Sixty Cents a Month **Seven Dollars a Year**

New York Office.....31 and 32 Tribune Building
Chicago Office.....905 and 906 Boyce Building

The Gazette is on sale at the News Stands in every City in Colorado and also in the following hotels in the east:

Auditorium Annex .....Chicago
Waldorf-Astoria .....New York

The Gazette is on file for the free use of readers in the reading rooms of:

Fifth Avenue Hotel .....New York
Waldorf-Astoria .....New York
Credit Lyonaise .....Paris
Munro & Co., 7 Rue Scribe .....Paris
American Rendezvous, 2 Cockspur St.....London

The Gazette is delivered to regular subscribers by early morning carriers in Denver, Boulder, Cripple Creek, Victor, Pueblo, Canon City, Florence, Colorado Springs, Manitou, Colorado City and Broadmoor, and can be obtained from the newsboys and at the news stands in each of the above places.

The next message Tesla gets from Mars will undoubtedly be "Advertise in the Gazette."

The Colorado Springs Gazette January 9, 1901

NIKOLA TESLA AND HIS TALK WITH OTHER WORLDS

Special to the Philadelphia Inquirer.

New York, Jan. 2.—Not quite two years ago, Mr. Nikola Tesla went out to Colorado to conduct experiments in relation to the wireless transmission of energy which has engaged his attention for several years.

Mr. Tesla dwelt on his work to an Inquirer man this afternoon. He regards his latest results as the most important he has ever attained. Briefly Tesla has been able to note a novel manifestation of energy which he knows is not of solar or terrestrial origin, and being neither, he concludes that it must emanate from one of the planets.

While he was conducting his investigations in his Colorado laboratory the instrument he was using to observe the electrical condition of the earth was affected in an unaccountable manner. It recorded three distinct, though very faint, movements, one after the other.

May Talk With Other Worlds.

These movements were observed not once but many times, the number of impulses varying, and Mr. Tesla now firmly believes that with improved apparatus it will be quite possible for the people of the earth to communicate with the inhabitants of other planets. In tetiling about his work and his discoveries, Mr. Tesla said:

"I set out to carry on my experiments along three different lines; first, to ascertain the best conditions for transmitting power without wires; second, to develop apparatus for the transmission of messages across the Atlantic and Pacific oceans, on which problem I have been engaged for eight years, and third, to work on another problem which involves a still greater mastery of electrical forces, and which, with my present knowledge, I consider of still greater importance than even the transmission of power without wires, and which I shall make known in due course.

Pressure of 50,000,000 Volts.

"There were, however, numerous points to be found out about electrical vibrations, and there were actions on which I was still in doubt. In my laboratory in New York I was able to go only to electrical discharges of 16 feet in length, and I had only reached effective electrical pressures of about 8,000,000 volts. To carry the problems on which I was working farther I had to master electrical pressures of at least 50,000,000 volts, and electrical discharges were necessary for some purposes measuring at least 50 or 100 feet.

"The results I attained were far beyond any I had expected to reach. One of the first observations I made in Colorado was of great scientific importance, and confirmatory of a result I had already obtained in New York. I refer to my discovery of the stationary electrical waves in the earth. The significance of this phenomenon has not yet been grasped by technical men, but it virtually amounts to a positive proof that with proper apparatus such as I have perfected a wireless transmission of signals to any point on the globe is practicable.

Sparks One Hundred Feet Long.

"In perfecting my apparatus I encountered at first great difficulties. I had a few narrow escapes from sudden sparks jumping out to great distance and a number of times my laboratory caught fire, but I carried all the work through without a serious mishap. I gradually learned how to confine electrical currents of a pressure of 50,000,000 volts to produce electrical movements up to 110,000-horse power, and I succeeded in obtaining electrical discharges measuring from end to end 100 feet and more. These results were, however, rendered more valuable by the fact that they opened up still greater possibilities for the future.

"It was in investigating feeble electrical actions transmitted through the earth that I made some observations which are to me the most gratifying. Chief among these certain feeble electrical disturbances which I could barely note occurred, and which by their character unmistakably showed that they were neither of solar origin nor produced by any causes known to me on the globe. What could they be?

"I have incessantly thought of this for months, until I finally arrived at the conviction, amounting to almost knowledge, that they must be of planetary origin. As I think over it now it seems to me that only men absolutely stricken with blindness, insensible to the greatness of nature, can hold that this planet is the only one inhabited by intelligent beings.

Communication With Mars.

"I have perfected my transmitting apparatus so far that I can undertake to construct a machine which will without the least doubt be fully competent to convey sufficient energy to the planet Mars to operate one of these delicate appliances which we are now using here, as, for instance, a very sensitive telephone instrument.

"With regard to my work in other lines which I have simultaneously carried on my progress has been most satisfactory, and I hope that soon electrical energy may be turned to the usages of man in a way and for purposes such as to surpass in importance all that we have ever done heretofore."

TESLA PREPARES TO SEND MESSAGES TO MARS.

The Electrician Says That He Will Soon Be Able to Establish Communication with That Planet.

Believes Martians Have Signalled Earth and That Unintelligible Messages Have Been Received.

Expects to Have Definite Results at an Early Date—Marconi Thinks the Scheme Is a Feasible One.

But one idea dominates my mind. That—my best and dearest—is for for your noble cause. Brethren, we have a message from another world, unknown and remote. It reads: ONE—TWO—THREE.—Nikola Tesla in the Journal, January 1, 1901.

Any proclamation coming from Tesla will be received with considerable incredulity. His assertion is remote to the point of impossibility.—Professor S. I. Brown, United States Naval Observatory, January 3, in the Journal.

You can rest assured that it is imaginative and visionary.—Professor A. S. Skinner, United States Naval Observatory, January 3, in the Journal.

I have read of the alleged discovery made by Tesla but would rather not spea kof it. Professor T. J. J. See, United States Naval Observatory, January 3, in the Journal.

NICOLA TESLA, the great electrical experimenter, is busy at work on a transmitter and a receiver that he believes will establish as an accomplished fact communication between this planet and Mars. When a reporter for the Journal saw him yesterday, in his laboratory, at No. 46 Houston street, he was drawing on paper zig-zag lines that looked like the teeth of an old-style up-and-down mill saw.

"I am preparing," he said, "for the greatest experiment that has ever been made on this planet. Sooner or later I shall establish communication with Mars. I am certain that the inhabitants of that planet have many times endeavored to signal this earth, but we have never had instruments of sufficient delicacy to receive their messages, nor instruments powerful enough to answer them. At last we have the former, and I will soon have the latter.

"It will remain then only to decipher their messages and answer them.

"Martians More Advanced."

"It is more than possible that the Martians will read our messages to them before we can read theirs, because I believe they are a more advanced people than we are.

"Already I have a transmitter that is, I am certain, of sufficient power to send a message to Mars with strength enough to operate a delicate telegraph instrument. A beginning has been made and the great result will soon be achieved."

Signor Guiseppe Marconi, the inventor of wireless telegraphy, said to the London correspondent of the Journal yesterday:

"It is not impossible to realize telegraphic communication between the earth and Mars, provided Mars is inhabited. Electrical science is able to overcome the millions of miles that interpose between us. Mr. Tesla is, I believe, sure to succeed in his efforts to establish this communication.

"With regard to wireless communication between London and New York, and messages flashed across the ocean for a half penny a word, I see no immediate prospect of such a consummation. At no very distant date, however, wireless communication between Europe and America will be a fact."

Only an Educated Guess.

Mr. Tesla shrugged his shoulders when a reporter for the Journal told him what Marconi had said.

"He knows nothing about what I have been doing, and if he has arrived at any conclusion it is but the conclusion of an educated guess. His wireless telegraphy has to do with this earth; mine deals with the stars. Let us both stick to our subjects.

"I see that Mr. Edison says he confines his thoughts below the apex of the Himalaya Mountains. Well, mine climb higher, and will reach their goal.

"Talking with Mars is not a new proposition. Other men than myself have received on delicate instruments messages they could not understand. My task is to receive them, to understand them and to reply to them.

"I will have some definite results soon, and when I get them I will explain all about them to the Journal."

The last remark appears to indicate that Mr. Tesla expects to receive the messages here in New York. When pressed to say whether he expected to establish Martian communication in this city he declined to answer.

MARS DESCRIBED BY C. FLAMMARION.

Great French Astronomer Says We Know More of Its Weather Than of the Earth's.

(Special Cable to the New York Journal and Advertiser.)

Paris, Jan. 9.—Camille Flammarion, the

nomical Society of France. After the lecture he summed it up for the Journal as follows:

"We know Mars better than the earth was known before the time of Columbus. We know the climatic conditions of Mars better than we know those of the earth today. We cannot tell what the weather will be to-morrow on the earth, but we all know what it will be on Mars, since it is always fair. Whereas no one has ever seen either the North or the South Pole of the earth, one pole of Mars is always observable. The conditions of observations are peculiarly favorable, on account of its proximity and because when Mars is in opposition it receives the full solar light.

"On Mars circulation of water takes place not by rain and rivers as on the earth, but by melted snows from the poles distributed over the planet by a system of canals. The circulation of water is horizontal instead of vertical as on the earth. Clouds on Mars are almost unknown. The canals as seen by astronomers are certainly water courses, but their dimensions are greatly exaggerated by growths of vegetation on each side, just as from a balloon the valley of a river on the earth appears to be the river itself.

"The melting of polar snows has a greater physical effect on Mars than on the earth. Here the polar seas are joined by oceans, and when there is a thaw at the Arctic Pole the rise of waters means a compensating depression at the Antarctic Pole. On Mars the great sea environing the South Pole has no connection with the seas about the North Pole, and the equilibrium of water in both hemispheres of Mars can be sustained only by canals. These canals run in straight lines for thousands of miles.

COMMUNICATION WITH THE PLANETS.

Mr. Tesla on Sir Norman Lockyer—Development of the Requisite Energy.

To THE EDITOR OF THE SUN—*Sir*. In your issue of Tuesday Sir Norman Lockyer, in commenting on my observations, is reported as having stated: "Communication with Mars is absolutely outside the domain of practical science."

Before I had obtained with electrical oscillations results such as were outlined in a recent article I would have unhesitatingly agreed to this statement, but now I have the unmistakable experimental evidence before me that the transmission of a message to that or some other planet is possible and, what is more, easily practicable.

Necessity of avoiding technical details, unintelligible to the general reader, compels me to illustrate the advantage of the new means of communication over the old by a comparison which, though not exact, is sufficiently correct to convey an approximate idea. Suppose that the entire available power of Niagara, about five million horse power, should be turned into an electric arc and transformed into an equivalent amount of radiant heat and light energy to be used for the purposes of signalling. Assume, further, that the observer in a planet at a distance of fifty million miles would be able to utilize integrally the energy falling upon one hundredth of a square mile of the planet's surface. This would be a difficult, if not impossible, task, but if he were successful, he would then only have 1—3,140,000,000,000,000,000th of that horse power available for the operation of his instrument.

On the other hand, let us examine how much energy could be conveyed by the methods and apparatus I have devised. In this case we should provide a conducting surface, connect it through a coil to the ground, and impress electrical oscillations upon this system. By availing ourselves of certain adjustments and artifices we should, according to my experiences, encounter no insuperable difficulties in setting up a movement of electrical energy equivalent to a rate of five million horse power, with but a small *actual* expenditure of energy. Supposing the observer in the planet should avail himself of similar means, we should then have, as in my system of energy transmission or telegraphy without wires, two resonating attuned circuits connected through a condenser. A great advantage would be at once secured, since the energy does not diminish with the square of the distance, as with light, heat or Hertzian rays, but in a linear proportion to the same.

Estimating the capacity of the condenser formed by the earth, the planet and the intervening medium, I find that we should be able to transmit in this manner to Mars, at intervals, energy at the rate of 1—50,000th of a horse power, which in the tuned circuit on the planet, by skilful construction and adjustment of the apparatus could be intensified to a rate of one-fifth of one horse power, and a considerable portion of this accumulated energy would be available for the operation of the receiving instrument.

The attainment of this enormous rate of energy delivery is made possible by the fact that in using these novel means we should not dissipate the energy of the transmitter uselessly in all directions through space, as we should when employing rays: We should simply transmit electrical stresses through the medium. It is as if we had a weightless, elastic bar extending from our globe to the planet, and as if we were transmitting energy by pushing this bar back and forth. The above rough estimate is obtained by ignoring the disturbing influences of the sun and of other planets, but by making all due allowances we could still convey to its place of destination an amount of energy many million times that possible with radiant light or heat. As far, then, as our ability of communicating with Mars is concerned, far from believing it impossible, we are justified in considering it practicable.

Why should Sir Norman Lockyer doubt that the energy would reach the planet? Does not the fact that electric disturbances are produced in the earth by changes in the sun offer a sufficient warrant? While I do not consider myself infallible, I feel confident that I am neither capable of mistaking earthquakes for novel electrical manifestations, nor incapable of noting what might have escaped the attention of others. I did not state that I had obtained a message from Mars. I only expressed my conviction that the disturbances I observed were of planetary origin. It does not follow that they could be detected by magnetic instruments. These are delicate only in a certain sense; in another sense they are very crude. Sir Norman Lockyer asks what ground I have for assuming Mars inhabited? I do not hesitate to admit that I am convinced of it. Perhaps part of my conviction is derived from the perusal of Sir Norman Lockyer's admirable papers. I am sorry he attaches no value whatever to my observations.

NIKOLA TESLA.

NEW YORK, Jan. 9.

Concentrates.

THE recent published vagaries of Nikola Tesla are not to be given serious attention and are interesting only for their notable absurdity.

The New York Tribune January 12, 1901

MARTIAN TELEGRAPHY DISCREDITED.

WASHINGTON SCIENTISTS CONSIDER TESLA'S CLAIMS ABSURD.

Washington, Jan. 11 (Special).—Scientists in Washington are inclined to regard the reports concerning recent experiments which are said to have facilitated the establishment of communication between the earth and Mars as wild theories, nor do they expect to hear of the success of such experiments. "It is a fanciful idea of Mr. Tesla's," said Professor Skinner, of the Naval Observatory, today, "and I do not think it is based on scientific principles. I believe that Tesla is an exceptionally brilliant man. He has done much wonderful work, but I take no stock in his new proposition, and, indeed, I have talked with no scientific men who do not consider Tesla's claim absurd."

Professor Eichelberger, also of the Naval Observatory, said that he first heard of Mr. Tesla's plans when a friend called his attention to a newspaper clipping. "Had I seen the story when it was first published I would very likely have glanced over it, thinking that it was not worth reading," he said. "I do not believe that anything is impossible which is to be performed in the future. At the same time I do not say that Tesla's claims are possible or even probable. Ten years ago no one would believe in some of the remarkable work he has since made practicable, therefore we cannot tell what is to happen in the future. Although wireless telegraphy has been so established that it must be recognized as a method of communication, as yet the science is in its infancy and great developments are to be expected as the outgrowth of the principles embodied in the Marconi and similar systems. All that I can say further is that we will be glad to hear of Mr. Tesla's success in fully establishing communication with the Martians, assuming, of course, that the planet is peopled. I think he will have no difficulty in convincing scientists of the practicability of such a scheme when he produces the proper evidence."

Father Hargan of Georgetown College, has been ill for several days with the grip, and was unable to talk about Tesla's plans to communicate with Mars, but he has been credited by other members of the faculty with having said that Tesla's plan was not an intrinsic impossibility. It is understood that he would not discuss the matter further.

Tesla Has a Message from the Stars.

Nikola Tesla gave to friends interested in the Red Cross movement this century greeting: "The retrospect is glorious, the prospect is inspiring. Much might be said of both. But one idea dominates my mind. This—my best, my dearest—is for your noble cause. I have observed electrical actions which have appeared inexplicable. Faint and uncertain though they were, they have given me a deep conviction and foreknowledge that ere long all human beings on this globe, as one, will turn their eyes to the firmament above with feelings of love and reverence, thrilled by the glad news: 'Brethren! We have a message from another world, unknown and remote. It reads: One—two—three—'"

Mr. Tesla states that in some experiments which he has been conducting for some time he has been noticing disturbances that have had a peculiar effect on his oscillatory instruments. "What these disturbances are caused by," says Mr. Tesla, "I am unable to say at present, but I am firmly convinced that they are the results of an attempt by some human beings, not of our world, to speak to us by signals. I am certain of some points in connection with these things I have noticed. I am absolutely certain that they are not caused by anything terrestrial. I know, too, that they are not caused by the sun or moon, and hence I am forced to the belief that they come from some other planet.

That we can send a message to a planet is certain. That we can get an answer is probable. Man on earth is not the only being in God's great system of worlds that is in possession of a mind."

The inventor sees no reason why communication cannot be opened in a comparatively short time with either Mars or Venus, or perhaps both, and suggests an electrical vibratory method of signal service.

NEW YORK, SATURDAY, JANUARY 19, 1901.

THAT MESSAGE FROM MARS.

It has been stated by an authority, whose weight will be determined by the mental attitude of his readers, that the day is near at hand when we shall be able to communicate with the other planets and preferably with Mars. It seems that in searching for a suitable location for a laboratory in which to conduct experiments in the wireless transmission of energy, Nicola Tesla found the desired conditions at a point some ten miles from Pike's Peak, at an altitude of several thousand feet above the sea. During the eight or nine months wherein Mr. Tesla was busy in the rarefied atmosphere of his laboratory, he seems to have produced some very spectacular effects; for, whereas in his New York laboratory, he was able to produce electrical discharges only 16 feet in length, and of 8,000,000 volts pressure, he here gradually "learned how to confine electrical currents of a pressure of 50,000,000 volts; how to produce electrical movements up to 110,000 horse power," and that he finally succeeded in "obtaining electrical discharges measuring from end to end 100 feet and more." Yet, in spite of his familiarity with 50,000,000-volt currents, Mr. Tesla did not disdain to study "certain feeble electrical disturbances which, by their character, unmistakably showed that they were neither of solar origin nor produced by any causes known to" him "on the globe." After deep thought upon the subject, he has finally "arrived at the conviction, amounting almost to knowledge, that they must be of planetary origin."

It would be interesting, and possibly vastly entertaining, to be supplied with the process of ratiocination by which Mr. Tesla deduces from the existence of certain puzzling electrical disturbances his "conviction, amounting almost to knowledge," that these disturbances had been launched at our particular planet from some other planet (preferably Mars), that was desirous of intercourse. Signor Marconi has suggested that these disturbances (which seem to have worked with such brilliant results upon Mr. Tesla's imagination) were due to atmospheric electricity which is especially active at such a high altitude as that of Mr. Tesla's laboratory; and Sir Norman Lockyer pertinently asks why, if electrical energy had been transmitted from Mars, it should have made its presence manifest in Colorado only; since all magnetic observatories in the world would have been simultaneously aware of it?

That some of the planets may be inhabited is possible, and there is nothing in our present knowledge of electricity absolutely to forbid the hope that in some future day we may learn how to fling forth intelligible electrical impulses into inter-planetary or even inter-stellar space; but it will certainly need something more than mere observations of some unexplained electrical impulses on a Colorado mountain to prove to a demonstration either the one proposition or the other.

A Canadian Rival of Tesla and Marconi.

Prof. E. S. Wiggins, of Ottawa, Canada, has just published a disquisition upon the subject of Tesla's experiments to establish telephonic communication with the planet Mars, in which the former makes a startling assertion in regard to Marconi's discovery, and expresses strong disbelief concerning Tesla's claim of having mechanical and electrical devices by which electrical energy can be forced through space. Prof. Wiggins, however, considered it quite possible for the earth to have electrical communication with Mars, but deprecates the idea of forcing a current of electricity from the earth to Mars. Electricity, he claims, exists only on the surface of bodies. The surface of our own planet's atmosphere is covered by a lake of electrical energy, and no little current, such as Tesla describes, could pass through it without being absorbed.

"Communication with Mars can be established," Prof. Wiggins proceeds, "by Marconi's method, which I discovered and published in 1893, two years before Marconi began his experiments. That is, by elevated points on the same body or planet or different planets. Remove all our mountains but the highest peak. Upon this place an electrical instrument and it will affect a similar one on Mars, especially if the sun, earth and Mars are in conjunction. I am almost certain that, with a proper instrument on the summit of Mount St. Elias we could even now telegraph to the planet Mars. The nick in the edge of that planet, seen by Lowell and Javelle, July 19, 1894, was no doubt an enormous pinnacle, erected to communicate with the planets Jupiter and Saturn."

Speaking upon the question of his claim that Marconi founded his system on the published theory of Prof. Wiggins, and the latter's purpose to demand his right in the honor and emoluments accruing from the new discovery, the professor says: "Surely the philosopher, who by years of study evolves a theory, should be equally rewarded with the man who puts it to the practical test, by having a legal right in all patents. If Marconi does not give me a share of the proceeds from his French patents, I will appeal to Her Majesty, through Sir Wilfrid Laurier and His Excellency, the Governor-General of Canada, as a British subject, and ask for equal right in his patents for the British dominions. I will make the same representations to the President of the United States. My appeal to the latter will be based on the fact that my essay for the Hodgkin's prize of $10,000 was submitted by the Smithsonian Institute at Washington to the French scientists for examination in 1894, and it was from this essay Marconi first learned that the earth's electric energy collects in hills, mountains—in fact, all elevations on her surface. Marconi immediately began to erect towers, and, placing instruments upon their summits, they answered each other.

"But I am now even with him, for I have discovered that the telephone acts on the same wireless principle, and I will ask patents from Canada, Britain and even from France, and my telephone will thus supplant his telegraphy. Then, railway companies will take down their wires, for conversation can be conducted between stations, and even running trains; generals can talk with each other while the battle is raging by merely sticking their swords into the ground; ships will also speak with each other miles away, while we can converse, stretching our limbs upon the grassy lawn here, with the weary traveler trudging his icy way to the northern pole."

Prof. Wiggins further states that volcanoes, like Vesuvius and Ætna, owe their heat entirely to the electric energy that they collect from the adjacent seas, mountains and country. He predicts that before the close of the twentieth century, towers of great height will be built all over the continents and on the sea; and these, burning by the earth's electric energy, will give eternal light to the surface of our planet. With small towers with wire coils, the summits of the Rockies could now, at little expense, become a row of glowing torches from Cape Horn to the Arctic Circle.

LETTER TO THE EDITORS.

Wireless Telegraphy Over Frozen Ground.

To the Editors of Electrical World and Engineer:

Sirs:—I should like to make a correction in your columns of a statement made by me in the discussion on Wireless Telegraphy at the Am. I. E. E. meeting of last year. I there stated that according to my experiments frozen ground made little difference in the transmission of signals, the waves apparently going down to the moisture under the frozen surface.

Whilst this statement was correct for the case tested, it does not hold always. The experiments on which I based this conclusion were made on a gravelly soil, with cinders overlying a clay bottom. Consequently, the frozen moisture was probably highly charged with salts, and was a fair conductor.

I have, within the past few months, had an opportunity of testing the effect over a stretch of land of a different nature. Two stations between which I have been working—one at Cob Point, Md., the other at Arlington, Va.—are 47 miles apart, the line between them passing entirely over open land, with the exception of half a mile of water, and through the City of Alexandria, a few miles from Arlington. The land is practically all well wooded, and the trees of considerable height.

Several sets of measurements were made in fine weather, and fairly accurate results obtained. A severe frost then set in, and the ground was frozen to a depth of several inches. It was found that under these conditions the signals received had only one-seventh the power of those received in warm weather; that is, for equally good transmission, we had to use seven times the power that we used in warm weather. It is evident therefore that in some places, possibly in most places, frost will form a very serious obstacle. I may say that the ratio will not always be one-seventh, but will be still larger for longer distances.

In this connection I would point out that the usual formulæ for

the capacity of a vertical wire or cylinder are not correct, being from 500 to 1000 per cent out. After considerable labor, I have succeeded in getting approximately correct formulæ, which I will give later. The usually given formula for the self-inductance is also incorrect, but the correction has been given by Heaviside. As an example of the approximate accuracy of the new formulæ, the calculated wave length was 254 ft. and the actual length as measured was 250 ft.

The design of stations for wireless telegraphy is now on exactly the same footing as the design of telegraph lines, and the laws are now fully understood. It is perhaps unnecessary to add that the various wild hypotheses of equipotential surfaces in the air or in the ground, of "wobbling" earth charges, etc., have been definitely disproven, the matter being a plain, simple case of ordinary electrodynamics.

With regard to the so-called Martian signals, these external disturbances have long been known, and only the crassest ignorance could attribute any such origin. They formed at one time a serious obstacle to multiplex systems, but are now eliminated. The different kinds are easily distinguishable, i. e., those due to lightning flashes anywhere within 100 miles or more, those due to street cars, etc., and those due to the gradual electrification of the vertical conductor by the air currents. This last gives, unless eliminated, signals at regular intervals, and by those ignorant of the subject, might be mistaken for intelligent signals.

Some work was done with the coherer, for the purpose of making comparative tests. Lodge's theory was confirmed. After long use the particles are found strung together in groups by thin ligaments of metal. Decohering can be obtained with all metals yet tried. The action observed is as follows: With small discharges the microscopic points of contact are fused off and the circuit opened. This gives decoherence. With greater discharges, the points are fused, but the fusion extends over a greater extent, and the electrostatic attraction draws out a thin tongue of melted metal till the gap is bridged. This gives coherence. Arsenic and other metals which do not fuse (except under great pressure) do not cohere, except when oxidized slightly on the surface. Then a discharge sufficient to reduce the oxide causes coherence, but a larger current burns away the contact points and causes decoherence; and as the metal does not fuse, larger currents do not cause coherence. The action of such materials as silver bromide is due to the fact that, after reduction and coherence, the now active bromide combines again with the silver. I gave a description of a coherer worked on this principle about a year and a half ago, in a review I wrote on Lodge's book, for this journal. All of Bose's experiments are therefore quite in accordance with Lodge's theory.

The amount of senseless and sensational stuff which has been written about wireless telegraphy suggests that the little knowledge, which the poet assures us is a dangerous thing, may have a certain function. That is, a very small amount of knowledge gone bad, of no particular use even to the owner, may yet, when spread in a thin film over the columns of the newspaper, give rise, by its very superficialty and tenuity, to a pleasing and striking iridescence. But, after all, it is only scum, and an evidence of the drink underneath. The fount of truth has another appearance.

WASHINGTON, D. C. R. A. FESSENDEN.

DIGEST
OF
CURRENT ELECTRICAL LITERATURE

Electro-Physics and Magnetism.

Point Discharge from a Tesla Pole.—Knoblauch.—An investigation of the following phenomenon: The discharge from a Tesla pole charges an insulated metallic plate positively at a certain distance and negatively at a greater distance. This is due to the greater speed and penetrative power of the negative ions. He has studied the distribution of the ions by means of perforated plates, and found that the positive charges are due to visible brush-discharges. When these brush discharges are prevented from impinging upon the plate by cutting out a central portion, no positive charge is obtained. The positive ions are strongest in the axial portion of the discharge.—*Phys. Zeit.*, Dec. 15; abstracted in Lond. *Elec.*, Jan. 4.

SCIENCE AND INVENTION.

AN ALLEGED MESSAGE FROM MARS.

IT is claimed by Nikola Tesla, if we are to believe interviews published in the daily papers, that while he was experimenting recently with long-distance space-signaling, his instruments persistently recorded a signal that could not have originated on the earth and must have come from some point outside. He believes that it may have been an attempt on the part of intelligent beings in Mars to communicate with us. In an interview printed in the New York *Herald*, Mr. Tesla is made to speak as follows:

"In my investigations, disturbing atmospheric influences were almost wholly excluded. It would have been impossible for other experimenters to note the effects which I have discovered, for with the Hertzian devices only a very narrow region can be explored, whereas I was able to observe the electrical condition of a large portion of the globe, a stretch of land 2,200 miles in width and breadth. That these actions are due to causes heretofore unknown I am convinced.

"I feel that I have not been led away by my imagination, but that my sight was true as ever before, and I am confident that future investigation will confirm my statement.

"Nor have I the slightest doubt, judging from my experiments and measurements, that with a properly constructed electrical oscillator an amount of energy can be transmitted to a planet, as Venus or Mars, even at their greatest distance, sufficient to bring into action a sensitive instrument, such as I have been using in my own observations.

"Furthermore, it is an error to believe that a great expenditure of power is necessary for interplanetary communication. What is needed is an effect specifically great—an enormous rate of energy delivery, but lasting each time only a fraction of a second, so that the total power used up is small. Now, with my oscillator I can make this rate equal to five million horse-power and more, if necessary, and my calculations show that a small fraction of this rate is amply sufficient for conveying a message to Mars.

"Heretofore light was the only known agent for communicating with a planet. It is easy to show that by its means such a result is virtually impossible, owing to the rapid diminution of energy, with the distance and the impossibility of concentrating in an instrument the energy falling upon a large area. By the method and machinery I have devised we are enabled to convey an immeasurably greater amount of energy to the planet, and the observer there, instead of utilizing in his instrument only an infinitesimal amount of the entire energy conveyed, can avail himself of a large portion of the same.

"A practical solution has thus been found both for transmitting and receiving messages, and we can only hope that there are beings as far advanced, and possibly further than we are ourselves. I see no harm in holding fast to this possibility. This thought can not but make us better and give us a fresh interest in life."

Scientific journals have not commented upon these claims, and other scientific men, when interviewed by reporters of the daily press, have expressed incredulity. Some have been outspoken in ridicule. An interview is printed in *The Sun* (January 8), purporting to have been held with Sir Norman Lockyer. Sir Norman is reported in a later issue to have denied the substance of this interview, and to profess admiration and respect for Mr. Tesla's work. What Sir Norman is represented to have said does, however, fairly well represent the general attitude of the scientific world, and we reproduce it here. He is reported as saying:

"I attach no importance whatever to them [electrical disturbances reported by Tesla]. The earth is always in a state of vibration. When these vibrations are on a large scale they are called earthquakes. When they are infinitesimal, they are not noticed, except by the most delicate magnetic instruments. If Mr. Tesla received a message from Mars, the electric transmitory influence must have been general, not local.

"Why should electric energy transmitted from Mars have made its presence manifest solely in Colorado? All the magnetic observatories in the world would have been aware of it simultaneously. Paris, Peking, Berlin, and Moscow would have recorded it as soon as Colorado. Any solar magnetic disturbance affects the whole earth, and the same law governs planetary disturbances. Thus the whole of our planet would be conscious of a message from Mars at the same moment.

"Regarding the immense accumulation of electrical energy which Mr. Tesla says is necessary for the delivery of his interplanetary signals, it is quite possible for him to concentrate the enormous electrical power he speaks of. He can also launch it into space, but whether it would reach Mars is more than I should like to assert."

The editorial comments of the lay press are various. The Philadelphia *Inquirer* believes that "one man's opinion is as good as another's" on such a subject, but is disinclined to credit Mr. Tesla. The Boston *Journal* is inclined to doubt the accuracy of the interviews with Tesla, and concludes that the true scientist is content with demonstrating facts. "Beyond that kind of demonstration," it says, "the wise man will not venture." The Providence *Journal* publishes half a column about what would be true if Tesla's assertions are to be credited; but it ventures no opinion as to the facts in the case. Mr. Garrett P. Serviss writes in the Atlanta *News* on methods by which it might be possible to communicate with the inhabitants of a planet, and on devices that they might be expected to use to attract our attention; but he, too, fails to state either belief or disbelief in Mr. Tesla's reputed claims. There can be no doubt, however, that the scientific world believes him to be either trying to make a new sensation out of nothing, or to be the victim of self-deceit. As the Boston *Herald* puts it:

"The readers of Mr. Tesla's periodical announcements have borne patiently with his flights of fancy. At the same time it seems pertinent to remind him that in performance he has fallen several long laps behind promise. The world has yet to witness the realization of revolutionizing discoveries for which he claimed credit. . . . There is not an electrical advance of note which has failed to elicit from him a definite and specific asseveration that he would presently bring it to a wonderful state of perfection.

"During the earlier stages of his career Mr. Tesla did accomplish some practical results; but the clear-headed technologist who deals in concrete facts seems to have been merged in the dreamer, who beguiles his hours with fantastic visions and lives in a realm of unreality."

TESLA'S WIRELESS LIGHT,

MAKES SCARCELY ANY HEAT, AND CLOSELY RESEMBLES SUNLIGHT.

Based Upon an Entirely New Principle, and the Inventor Says It Will Purify the Atmosphere and Kill Disease Germs—Also Exercises Soothing Effect Upon the Nerves.

Nikola Tesla gave to THE SUN yesterday an authorized statement in reference to his new light, described the lamp which diffuses the light and then, darkening the windows of his laboratory in East Houston street, turned on an electric current, and in a moment the rooms were flooded with what Tesla calls "artificial sunshine." The light was diffused through a spiral of glass about eight inches high and six inches wide. The spiral is of glass tubing, about one-quarter of an inch in diameter, the ends being blown to about double the size of the tybe and closely resembling wax candles. The general effect of the lamp is that of a small box made of glass tubing with two candles lying on their sides along the top. The ends of the spiral which resemble candles are covered with a thin coating of metal and painted white. The lamp illuminates whether it is connected by wires with an electric current or not. Mr. Tesla operates it with and without wires. The wonderful thing about the wireless lamp is that it may be carried about from one part of a room to another, picked up and set down at will, just as one would carry a kerosene lamp around, and all the time there is not so much as a flicker of the light.

But more than all this, Mr. Tesla asserts that in discovering this process of illumination he has discovered a light which will be of incalcuable value in the sick room and in the hospital ward. The tube of the lamp before being closed at one end is partly filled with certain gases, the properties of which Mr. Tesla is not quite ready to disclose, but which, he says, will purify the air of a sick room when it might endanger the life of the patient to have the windows opened, so that the room's atmosphere will be as pure as if the room had been flooded with outer air. The inventor asserts that so perfect is his invention that the "ozonizing" of a room, as he calls it, may be continued as long as desired and stopped at will. Tesla says that his artificial sunshine, or his "sanitary light," is intended to be his first gift to the new century, the practical result of years of experiment in the old. Here is Mr. Tesla's statement:

"This light is the result of continuous efforts since my early experimental demonstrations before scientific societies here and abroad. In order to make it suitable for commercial use, I had to overcome great difficulties. One of these was to produce from ordinary currents of supply electrical oscillations of enormous rapidity in a simple and economical manner. This, I am glad to say, I have now accomplished and the results show that with this new form of light a higher economy is practicable than with the present illuminants. The light offers, besides, many specific advantages, not the least of which is found in its hygienic properties. It is, I believe, the closest approach to daylight which has yet been reached from any artificial source.

"The lamps are glass tubes which may be bent in any ornamental way. I most generally use a rectangular spiral, containing about twenty to twenty-five feet of tubing making some twelve to fourteen convolutions. The total illuminating surface of a lamp is from 300 to 400 square inches. The ends of the spiral tube are covered with a metallic coating and provided with hooks for hanging the lamp on the terminals of the source of oscillations. The tube contains gases rarefied to a certain degree, determined in the course of long experimentation as being conductive to the best results.

"The process of light production is, according to my views, as follows: The street current is passed through a machine which is an electrical oscillator of peculiar construction and transforms the supply current, be it direct or alternating, into electrical oscillations of a very high frequency. These oscillations, coming to the metallically coated ends of the glass tube, produce in the interior corresponding electrical oscillations, which set the molecules and atoms of the inclosed rarefied gases into violent commotion, causing them to vibrate at enormous rates and emit those radiations which we know as light. The gases are not rendered incandescent in the ordinary sense, for if it were so, they would be hot, like an incandescent filament. As a matter of fact, there is very little heat noticeable, which speaks well for the economy of the light, since all heat would be loss.

"This high economy results chiefly from three causes: First from the high rate of the electrical oscillations; second, from the fact that the entire light-giving body, being a highly attenuated gas, is exposed and can throw out its radiations unimpeded, and third, because of the smallness of the particles composing the light-giving body, in consequence of which they can be quickly thrown into a high rate of vibration, so that comparatively little energy is lost in the lower or heat vibrations. An important practical advantage is that the lamps need not be renewed like the ordinary ones, as there is nothing in them to consume. Some of these lamps I have had for years, and they are now in just as good a condition as they ever were. The illuminating power of each of these lamps is, measured by the photometric method, about fifty candle power, but I can make them of any power desired, up to that of several arc lights. It is a remarkable feature of the light that during the day it can scarcely be seen, whereas at night the whole room is brilliantly illuminated. When the eye becomes used to the light of these tubes, an ordinary incandescent lamp or gas burner produces a violent pain in the eye when it is turned on, showing in a striking manner, to what a degree these concentrated sources of light which we now use are detrimental to the eye.

"I have found that in almost all its actions the light produces the same effects as sunlight, and this makes me hopeful that its introduction into dwellings will have the effect of improving, in a measure now impossible to estimate, the hygienic conditions. Since sunlight is a very powerful curative agent, and since this light makes it possible to have sunlight, so to speak, of any desired intensity, day and night in our homes, it stands to reason that the development of germs will be checked and many diseases, as consumption for instance, successfully combatted by continually exposing the patients to the rays of these lamps. I have ascertained unmistakably, that the light produces a soothing action on the nerves, which I attribute to the effect which it has upon the retina of the eye. It also improves vision, just exactly as the sunlight, and it ozonizes slightly the atmosphere. These effects can be regulated at will. For instance, in hospitals, where such a light is of paramount importance, lamps may be designed which will produce just that quantity of ozone which the physician may desire for the purification of the atmosphere, or if necessary the ozone production can be stopped altogether.

"The lamps are very cheap to manufacture, and by the fact that they need not be exchanged like ordinary lamps or burners they are rendered still less expensive. The chief consideration is, of course, in commercial introduction, the energy consumption. While I am not yet prepared to give exact figures, I can say that, given a certain quantity of electrical energy from the mains, I can produce more light than can be produced by the ordinary methods. In introducing this system of lighting my transformer, or oscillator, will be usually located at some convenient place in the basement, and from there the transformed currents will be led as usual through the building. The lamps can be run with one wire alone, as I have shown in my early demonstrations, and in some cases I can dispense entirely with the wires. I hope that ultimately we shall get to this ideal form of illumination, and that we shall have in our rooms lamps which will be set aglow no matter where they are placed, just as an object is heated by heat rays emanating from a stove. The lamps will then be handled like kerosene lamps, with this difference, however, that the energy will be conveyed through space. The ultimate perfection of apparatus for the production of electrical oscillations will probably bring us to this great realization, and then we shall finally have the light without heat or 'cold' light. I have no difficulty now to illuminate the room with such wireless lamps, but a number of improvements must be made yet before it can be generally introduced."

The New York Tribune January 27, 1901

TESLA'S VACUUM TUBE LIGHT.

THE INVENTOR ENCOURAGED BY THE PROGRESS OF HIS WORK.

Mr. Tesla, who has been striving for years to produce an electric light without heat, feels that he is making perceptible headway in that work. As The Tribune has indicated before his general plan is to employ an alternating current of almost inconceivably great frequency, and a lamp consisting of a vacuum tube. The alternations are secured by an instrument of his own invention, known as the oscillator.

But after Mr. Tesla entered upon his interesting line of experiment he encountered various unforeseen difficulties. While he was able to obtain a beautiful light almost at the outset, it was at the expense of more energy than was desirable. In other words, he did not have his invention on a thoroughly satisfactory basis. By degrees he has improved the efficiency of his apparatus, so that his light is now more economical than it was, and he regards it as superior to both the incandescent and arc lights in this respect. At present, however, he is unwilling to indicate precisely the nature and degree of the technical advances made, or to use figures in comparing its economy with that of its rivals. One reason for reticence on the latter point may be a recognition of the possibility of further improvement. Mr. Tesla frankly declares that his lamp is not yet perfect. It does not make as good a return in light for the electrical energy invested as he would like. All that he insists upon is that it is now so efficient that he can conscientiously recommend it to those who may wish to put it on the market.

In some of his earlier experiments Mr. Tesla used a straight vacuum tube fully an inch and a half in diameter and six or eight feet long. Latterly he has employed a much more slender one, and by putting it into a rather compact coil saves a great deal of space. A score of lamps of this sort, each with a porcelain reflector over it, might be suspended from the ceilings of rooms on the tenth floor of an office building, while the special apparatus which modified the current for their use would be down in the basement. The street mains would supply an ordinary alternating current, and other wires would lead from the oscillator up to the lamps. For some purposes two wires to each lamp would be preferable but for others one would suffice. Less copper would be required for inside wiring, and the risks from escaping current would be diminished, rather than increased. The present style of insulation would be more than sufficient

TESLA'S NEW DISCOVERY.

CAPACITY OF ELECTRICAL CONDUCTORS IS VARIABLE

Not Constant, and Formulas Will Have to Be Rewritten—Capacity Varies With Absolute Height Above Sea Level, Relative Height From Earth and Distance From the Sun.

Nikola Tesla announced yesterday another new discovery in electricity. This time it is a new law and by reason of it, Mr. Tesla asserts, a large part of technical literature will have to be rewritten. Ever since anything has been known about electricity scientific men have taken for granted that the capacity of an electrical conductor is constant. When Tesla was experimenting in Colorado he found out that this capacity is not constant, but variable. Then he determined to find out the law governing this phenomenon. He did so, and all this he explained to THE SUN yesterday. Here is what he said:

"Since many years scientific men engaged in the study of physics and electrical research have taken it for granted that certain quantities, entering continuously in their estimates and calculations, are fixed and unalterable. The exact determination of these quantities being of particular importance in electrical vibrations, which are engrossing more and more the attention of experimenters all over the world, it seems to me important to acquaint others with some of my observations, which have finally led me to the results now attracting universal attention. These observations, with which I have long been familiar, show that some of the quantities referred to are variable and that, owing to this, a large portion of the technical literature is defective. I shall endeavor to convey the knowledge of the facts I have discovered in plain language, devoid as much as possible of technicalities.

"It is well known that an electric circuit comports itself like a spring with a weight attached to it. Such a spring vibrates at a definite rate, which is determined by two quantities, the pliability of the spring and the mass of the weight. Similarly an electric circuit vibrates, and its vibration, too, is dependent on two quantities, designated as electrostatic capacity and inductance. The capacity of the electric circuit corresponds to the pliability of the spring and the inductance to the mass of the weight.

"Exactly as mechanics and engineers have taken it for granted that the pliability of the spring remains the same, no matter how it be placed or used, so electricians and physicists have assumed that the electrostatic capacity of a conducting body, say of a metallic sphere which is frequently used in experiments, remains a fixed and unalterable quantity, and many scientific results of the greatest importance are dependent on this assumption. Now, I have discovered that this capacity is not fixed and unalterable at all. On the contrary, it is susceptible to great changes, so that under certain conditions it may amount to many times its theoretical value, or may eventually be smaller. Inasmuch as every electrical conductor, besides possessing an inductance, has also a certain amount of capacity, owing to the variations of the latter, the inductance, too, is seemingly modified by the same causes that tend to modify the capacity. These facts I discovered some time before I gave a technical description of my system of energy transmission and telegraphy without wires, which, I believe, became first known through my Belgian and British patents.

"In this system, I then explained, that, in estimating the wave-length of the electrical vibration in the transmitting and receiving circuits, due regard must be had to the velocity with which the vibration is propagated through each of the circuits; this velocity being given by the product of the wave-length and the number of vibrations per second. The rate of vibration being, however, as before stated, dependent on the capacity and inductance in each case, I obtained discordant values. Continuing the investigation of this astonishing phenomenon I observed that the capacity varied with the elevation of the conducting surface above the ground, and I soon ascertained the law of this variation. The capacity increased as the conducting surface was elevated, in open space, from one-half to three-quarters of 1 per cent. per each foot of elevation. In buildings, however, or near large structures, this increase often amounted to 50 per cent. per foot of elevation, and this alone will show to what an extent many of the scientific experiments recorded in technical literature are erroneous. In determining the length of the coils or conductors, such as I employ in my system of wireless telegraphy, for instance, the rule which I have given is, in view of the above, important to observe.

"Far more interesting, however, for men of science is the fact I discovered later, that the capacity undergoes an annual variation with a maximum in summer and a minimum in winter. In Colorado, where I continued with improved methods the investigations begun in New York and where I found the rate of increase slightly greater, I furthermore observed that there was a diurnal variation with a maximum during the day and a minimum during the night. Further, I found that sunlight causes a slight increase in the capacity. The moon also produces an effect, but I do not attribute it to its light.

"The importance of these observations will be better appreciated when it is stated that owing to these changes of a quantity supposed to be constant an electric circuit does not vibrate at a uniform rate, but its rate is modified in accordance with the modifications of the capacity. Thus a circuit vibrates a little slower at an elevation than when at a lower level. An oscillating system, as used in telegraphy without wires, vibrates a little quicker when the ship gets into the harbor than when on open sea. Such a circuit oscillates quicker in the winter than in the summer, though it be at the same temperature, and a trifle quicker at night than in daytime, particularly if the sun is shining.

"Taking together the results of my investigations I find that this variation of the capacity and consequently of the vibration period is evidently dependent, first, on the absolute height above sea level, though in a small degree; second, on the relative height of the conducting surface or capacity with respect to the bodies surrounding it; third, on the distance of the earth from the sun, and fourth, on the relative change of the circuit with respect to the sun caused by the diurnal rotation of the earth. These facts may be of particular interest to meteorologists and astronomers, inasmuch as practical methods of inquiry may result from these observations, which may be useful in their respective fields. It is probable that we shall perfect instruments for indicating the altitude of a place by means of a circuit properly constructed and arranged, and I have thought of a number of other uses to which this principle may be put.

"It was in the course of investigations of this kind in Colorado that I first noted certain variations in electrical systems arranged in peculiar ways. These variations I first discovered by calculating over the results I had previously noted, and it was only subsequently that I actually perceived them. It will thus be clear that some who have ventured to attribute the phenomena I have observed to ordinary atmospheric disturbances have made a hasty conclusion."

ter to the *Sun* the following details are given: "The lamps are glass tubes which may be bent in any ornamental way. I most generally use a rectangular spiral, containing about twenty or twenty-five feet of tubing making some twelve to fourteen convolutions. The total illuminating surface of a lamp is from 300 to 400 sq. ins. The ends of the spiral tube are covered with a metallic coating and provided with hooks for hanging the lamp on the terminals of the source of oscillations. The tube contains gases rarefied to a certain degree, determined in the course of long experimentation as being conducive to the best results." In this instance also Mr. Tesla has been very fortunate in departing from his custom by giving details, for the "gift to the New Century" appears to be merely the vacuum tube light, known now for almost two centuries. The description does not indicate any advance in principle over Hawksbee's work of 1709, nor any advance otherwise over the work of Geissler fifty years ago, or that of D. McFarlan Moore in recent years.

Tesla's Latest.

The New Century has already been enriched by two Tesla "discoveries," one of which he announces as his "first gift to the New Century." Several weeks ago he announced through the newspapers that certain electrical disturbances that had come under his observation were, he felt convinced, of planetary origin, which statement was followed up a few days later with another that he had discovered a means which rendered communication with Mars or any other planet not only possible, but easily practicable. Unfortunately for the credence of his claim, he added in a letter to the New York *Sun* some details which contradict all established ideas concerning the transmission of electric radiant energy, though the proposed means of communication with another planet purports to be based upon these same ideas.

The second and more recent announcement is that as the result of continuous effort since his first experimental demonstrations of years ago, he has at last perfected a means of producing "artificial sunshine," the new light being more economical and vastly superior to present forms of artificial illumination. In a letter to the *Sun* the following details are given: "The lamps are glass tubes which may be bent in any ornamental way. I most generally use a rectangular spiral, containing about twenty or twenty-five feet of tubing making some twelve to fourteen convolutions. The total illuminating surface of a lamp is from 300 to 400 sq. ins. The ends of the spiral tube are covered with a metallic coating and provided with hooks for hanging the lamp on the terminals of the source of oscillations. The tube contains gases rarefied to a certain degree, determined in the course of long experimentation as being conducive to the best results." In this instance also Mr. Tesla has been very fortunate in departing from his custom by giving details, for the "gift to the New Century" appears to be merely the vacuum tube light, known now for almost two centuries. The description does not indicate any advance in principle over Hawksbee's work of 1709, nor any advance otherwise over the work of Geissler fifty years ago, or that of D. McFarlan Moore in recent years.

At one time the frequent announcements by Tesla of revolutionary discoveries were a real source of harm to the electrical industry through giving rise to fears in the minds of investors that the current status of the electrical industry is insecure. The lay public appears, however, to have finally become surfeited with promises followed by no fulfillment, and the more recent announcements of Tesla have been received by the newspaper press with few exceptions—mostly of the "yellow" variety—in a changed spirit. Instead of serious consideration being given to his claims, he is rapidly becoming a subject for the irreverent mirth of the newspaper paragrapher, one of whom comments as follows: "Mr. Tesla is thus on the very eve of a discovery even more remarkable than the many others on whose eve he has been so often and so long. It may be asserted confidently that if any one on earth can understand Mars it is Tesla; and conversely, that if any one can understand Tesla, it must be an inhabitant of Mars." To quote sorrowfully an English electrical contemporary: "It is pitiable to see the engineer who invented the polyphase system of power transmission and who has done such valuable original work for other departments of electrical engineering, so fond of the cheap notoriety to be gained by sensational paragraphs in daily papers."

MR. TESLA'S SCIENCE.

To the Editor: In the *New York Sun* for January 3, Mr. Nikola Tesla has an article that deserves a word. The word is one of warning to all sober-minded readers to remind them that Mr. Tesla's recently published utterances have discredited him in the eyes of competent judges. In the *Century Magazine* for June, 1900, Mr. Tesla printed a long article, superbly illustrated with cuts that had little or nothing to do with his subjects, which dealt with a few electrical matters, and also with philosophic and social problems upon which he freely expressed a jumble of trivial, ignorant, pretentious and erroneous opinions. This article was freely reviewed in the POPULAR SCIENCE MONTHLY for July, 1900, and in *Science* for September 21. These reviews were doubtless seen by Mr. Tesla, but no word of reply has been made public by him. Indeed, he says in the *Sun* that from adverse criticisms on his work he experiences 'a feeling of satisfaction.' Any one who desires a standing among men of science is called upon to defend his public utterances when they have been seriously questioned in reputable scientific journals. Until an adequate rejoinder is received Mr. Tesla has no standing among professed men of science. He will have none among intelligent readers from the moment that the case is understood by them. It is not profitable to again go over the ground covered by the articles just mentioned, but readers are referred to them in passing.

The article in the *Sun* of January 3 bears the marks of authenticity. Much of it is printed in quotation marks. It gives an account of Mr. Tesla's work in Colorado during a part of the year 1899. This work had, he says, three objects: first, to transmit power without wires, and second, to develop apparatus for submarine telegraphy. These two problems have a direct commercial value. When they are solved, by Mr. Tesla or another, we shall hear of them through the Patent Office. As we have not so heard of them it is permissible to wait for results. We wish Mr. Tesla every success in these investigations. He is entitled to all the time he needs—a lifetime if necessary. If his experiments forward our present knowledge in any material degree he will be entitled to the gratitude of all mankind, and he will receive it. Until they do pronunciamentos from him and comments from us are not required.

The third problem upon which Mr. Tesla was engaged 'involves,' he says, 'a still greater mastery of electrical forces.' He will 'make it known in due course.' In the meanwhile, however, he states that he has noted "certain feeble electrical disturbances . . . . which by their character unmistakably showed that they were neither of solar origin nor produced by any causes known to me on the globe." These he supposes may have been signals from intelligent beings on Mars or some other of the 'twenty or twenty-five planets of the solar system.' Mr. Tesla obviously wants to figure in the newspapers. Every one would be greatly interested if it were true that signals are being sent from Mars. Unfortunately for Mr. Tesla's scientific standing, he has not adduced a scrap of evidence to prove it. It is of a piece with the 'twenty or twenty-five planets' he ascribes to the solar system. It would be interesting if there were so many. There is no evidence of it save Mr. Tesla's assertion, and assertions—Mr. Tesla's or another's—do not count in science. There is no further space for a notice of Mr. Tesla's latest extravagant vagary. For men of science no notice at all is needed. Any intelligent reader who will consult the reviews already mentioned and compare them with Mr. Tesla's own words will see that his vivid writings must be read with extreme caution. His electrical experiments being directed towards commercial uses must be judged by proved commercial success. His speculations on science are so reckless as to lose an interest. His philosophizing is so ignorant as to be worthless.

X.

CURRENT NEWS AND NOTES.

VACUUM TUBE LIGHTING.—According to newspaper reports Mr. Tesla is again working upon vacuum tubes. In an authoritative statement in the New York *Sun* he says: "The lamps are glass tubes which may be bent in any ornamental way. I most generally use a rectangular spiral, containing about 20 ft. to 25 ft. of tubing, making some twelve to fourteen convolutions. The total illuminating surface of a lamp is from 300 to 400 square inches. The ends of the spiral tube are covered with a metallic coating and provided with hooks for hanging the lamp on the terminals of the source of oscillations. The tube contains gases rarefied to a certain degree, determined in the course of long experimentation as being conducive to the best results." After discussing the subject in general terms, he adds: "I have no difficulty now to illuminate the room with such wireless lamps, but a number of improvements must be made yet before it can be generally introduced." Wherein this system differs from that of Geissler, Moore and the several earlier ones of Tesla, is not stated.

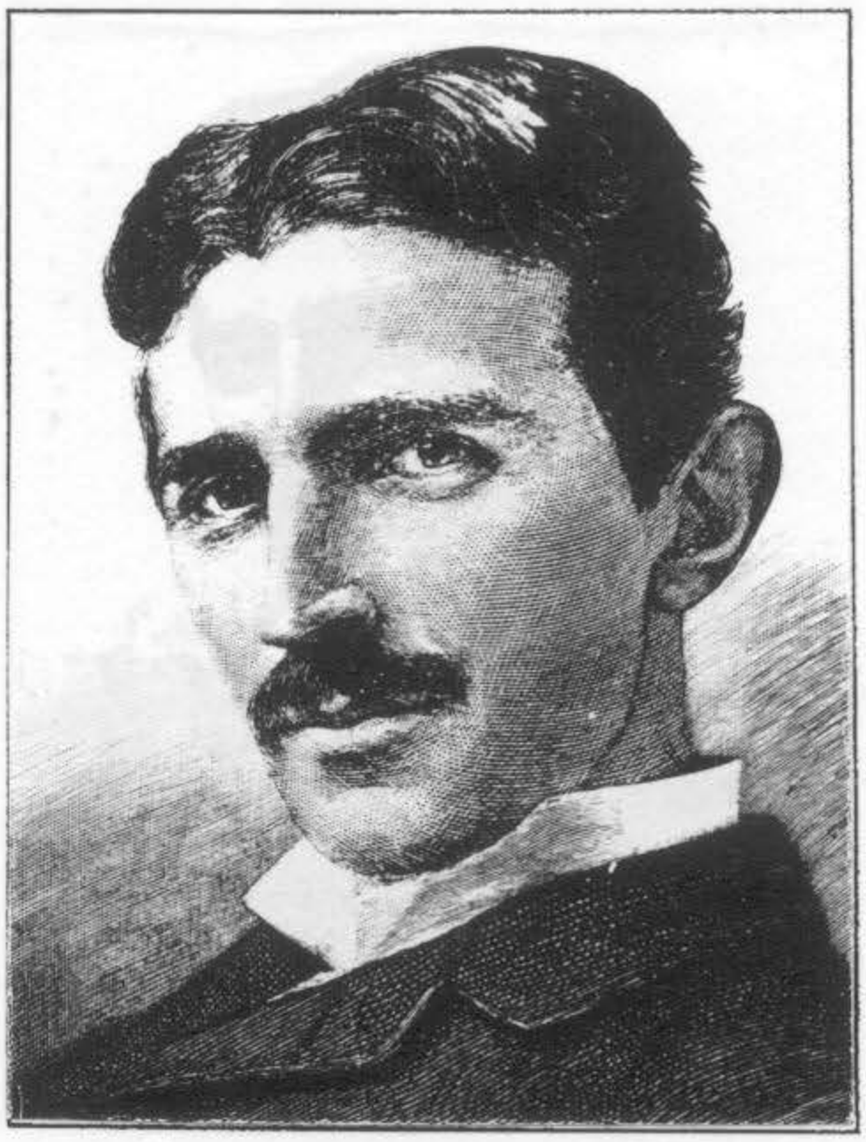
ANOTHER TESLA DISCOVERY.—Through the daily newspapers of Wednesday of this week Tesla announced another new discovery in electricity, which he says will require a large part of technical literature to be rewritten. The discovery is that capacity is not fixed and unalterable. In the announcement Tesla says he has found that capacity increases as the conducting surface is elevated in open space, from one-half to three-fourths of one per cent per each foot of elevation, though in buildings or near large structures this increase often amounted to 50 per cent per foot of elevation. Moreover, he says he has observed that there is a diurnal variation of the capacity, with a maximum during the day and a minimum during the night; and the astonishing statement is made that while both the sun and moon cause a slight increase in capacity, in the former case it is due to sunlight, but in the latter case not due to moonlight. Summing up, he says he finds that the variation of capacity is dependent upon the absolute height above sea level, though in a small degree; on the relative height of the conducting surface or capacity with respect to the bodies surrounding it; on the relative change of the circuit with respect to the sun, caused by diurnal rotation of the earth; and—on the distance of the earth from the sun! He considers it probable that instruments will be perfected for indicating the altitude of a place by means of a circuit properly constructed and arranged, and adds that he has thought of a number of uses to which this principle may be put. It is also said that inductance is seemingly modified by the same causes that tend to modify the capacity. Although no reference is made to the Pupin theory concerning the use of inductance in overcoming the disturbing effects of the capacity of telephone lines, the "discovery" appears to invalidate that theory.

MEN AND WOMEN OF INTEREST

NICOLA TESLA, the well-known electrician, has attracted the attention of the civilized world by his recent announcement that he had discovered a means by which it was possible to communicate

GUGLIELMO MARCONI.
Copyright, 1900, by Rockwood.

with the inhabitants of Mars. A system of wireless telegraphy, differing, however, from the Marconi system, is the power used in his experimental machine, which, he claims, has one twenty-fifth of the requisite force.



Mr. Tesla is an earnest worker along original lines. He was born forty-three years ago in the little village of Smiljam, Lika, an insignificant part of Servia. He is proud of his Slav blood. He is also proud of his three sisters, the youngest of whom was formerly considered the genius of the family. That was before her brother became the rival of Edison as an electrical wonder.

When a student at the University of Bologna, Marconi astonished his instructors by his novel ideas and original experiments. Although now only twenty-eight years old, he has astonished the world, not by ideas or experiments, but by one of the most wonderful inventions of the last century. As the inventor of wireless telegraphy his fame encircles the globe.

His mother was English, his father Italian, and Bologna was his birth-place. Meeting with neither recognition nor encouragement in his native land, in 1898 he went to England. Before leaving Italy he had clearly demonstrated the possibility of signalling without wires by means of Hertzian waves. In '99 he sent the first message across the English Channel.

Last year he came to the United States to make a test of his system before the Naval Board. Experiments were made on board the cruiser *New York* and the battle-ship *Massachusetts*, and messages were successfully sent across thirty-six miles of ocean.

The present state of the Czarina's health is of vital moment to all Russia. If the babe whose arrival is expected in May is not a boy, bitter will be the disappointment in the royal household and throughout the realm of the Czar. Already three daughters have been born to the Czar and Czarina. In case the Czar dies without male issue, the throne

NICOLA TESLA.

MISS MARY CONDIT-SMITH.

passes to his younger brother, the Grand-Duke Michael.

If all reports are true, the life of the Czarina has not been a very happy one. The people look upon her as an alien, foreign in her tastes and sympathies. The edict she caused to be issued forbidding the ladies of the court to smoke cigarettes did much to increase the animosity towards her.

She is a devoted wife and mother, and during the recent illness of the Czar she never left his bedside. It was at this time that the Czarina gave orders that no bulletins or information regarding the Czar's health should be sent out until they were first submitted to her. Baron Fredericks, Minister of Court, disobeyed this command by writing a personal letter to the Dowager Czarina. For this he was summarily dismissed by the determined young wife of Nicholas II.

The Grand-Duke Michael, who, in the event of the present Czar dying without male issue, would succeed to his brother's throne, is now in his twenty-third year. He has been a constant companion of his mother, the Dowager Czarina, making his home with her in Russia, and accompanying her in all her travels abroad. She is said to have thoroughly imbued him with the reactionary ideas and principles of his father, Alexander III.

It has been an accepted fact that the marriages of royal personages were not made in heaven, but in counsellors' chambers. But twentieth-century women, even though they be queens and princesses, will not bow to this time-honored custom. So "wilful Wilhelmina," as Holland's spirited young Queen is called by some who know her well, has chosen a husband for herself. He is a cadet of the ducal house of Mecklenburg-Schwerin, the little grand-duchy on the northeast coast of the German Empire. He is a good-looking young fellow, four years older than Wilhelmina, and the possessor of a vast amount of common-sense. There is nothing extraordinary about Duke Henry, even if he did please the fancy of a most fastidious Queen. He is the youngest child by his father's third marriage, and is closely attached to the German court, holding the commission of a lieutenant in the chasseur battalion of the Prussian Guard stationed at Potsdam. Whether skating, witnessing the manœuvres of her troops, leading her staff on horseback, opening provincial and agricultural shows, or tending her tulip-garden, Wilhelmina is the idol of her people.

The little Queen of Holland is one of the wealthiest European sovereigns, her yearly income from the civil lists being $15,000,000. In addition to this she has a large private fortune, inherited from her father.

Another independent young woman, when it comes to matrimonial matters, is the Princess Victoria, the second daughter of the

ALFRED GWYNNE VANDERBILT.

THE CZAR AND CZARINA OF RUSSIA.

Prince of Wales. She, too, has at last succumbed to Cupid's darts. Prince George of Greece is said to be the fortunate man. The Princess has long since been considered eccentric on account of her original ideas. It was said that she was the victim of two unfortunate love-affairs, and that it was her disappointment in failing to win recognition for either of her lovers that caused her to withdraw as much as possible from all gayety. At one time her queer, plain costumes, and her sad, distrait air, caused much comment and sympathy for a Princess who wanted first to be a woman.

As a second son, Prince George started life without any especially brilliant prospects. He was assigned to the navy. As commander of the Greek fleet he gave so good an account of himself during the Græco-Turkish war that the Powers in '98 appointed him Commissioner-General of Crete for three years.

In '91 Prince George visited the United States. He is tall, standing six feet three, with light complexion, kindly eyes, and an amiable expression. He took an active part in the Olympian games at Athens, and is the strongest man in the Greek navy.

The most interesting marriage of the season on this side of the water was that of Alfred Gwynne Vanderbilt, second son of Cornelius Vanderbilt, and Miss Elsie French, the daughter of the late Francis Ormond French. The young people had known each other from childhood and had been sweethearts for many years. In taste they were exceedingly congenial. Mrs. Vanderbilt is vivacious, chic, graceful, and pretty in a fresh, girlish way. She is not a beauty, however. She is fond of travel, adventure, and society, as is her husband. Mr. Vanderbilt is particularly devoted to automobiling and horse-back riding, and for less exciting diversion enjoys the theatres. Miss French was rich in her own right, her marriage dot being $3,700,000. Mr. Vanderbilt's inheritance from his father is estimated at $40,000,000.

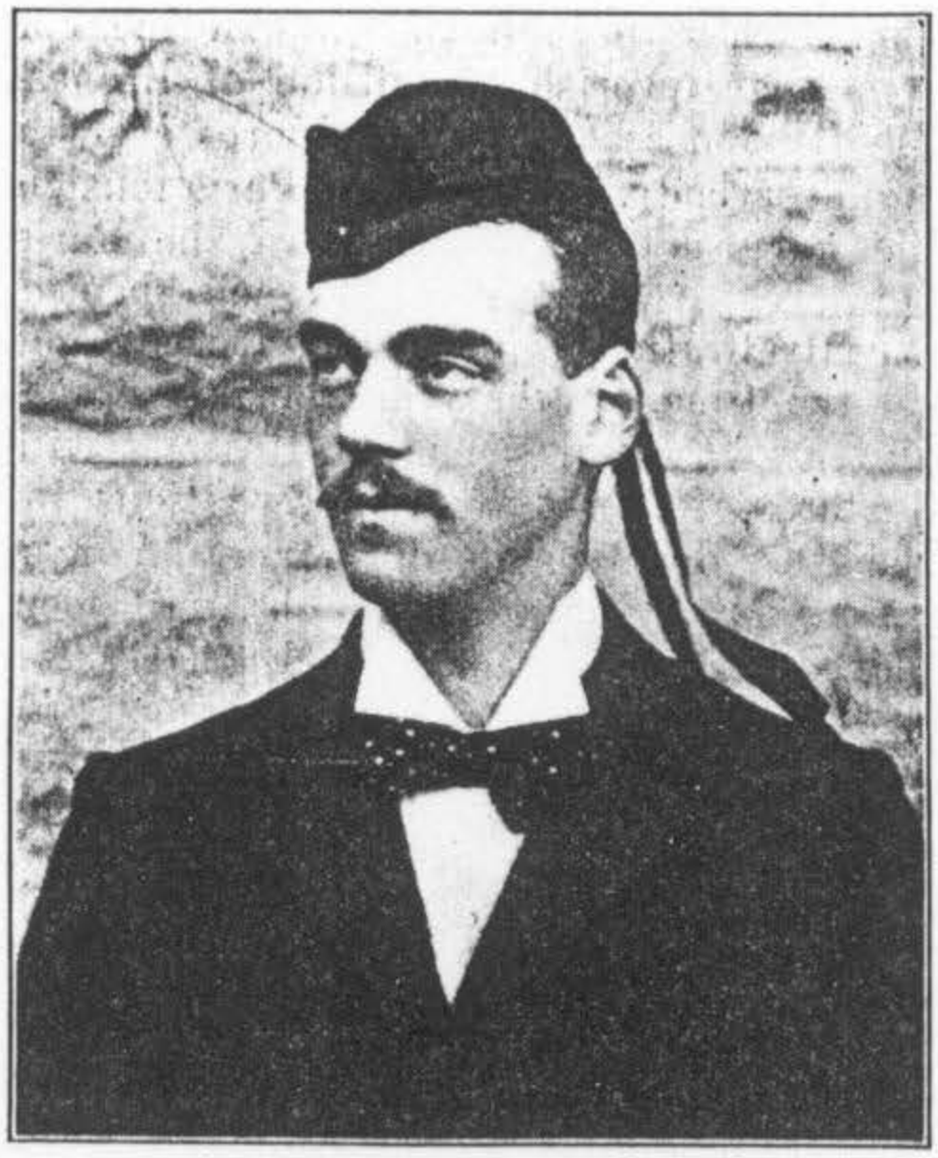
The marriage of Miss Mary Condit-Smith, of Washington, and Lieutenant Richard S. Hooker, United States Marine Corps, now stationed at the Brooklyn Navy-yard, will occur at the national capital February 11, and will be one of the most brilliant social events of an unusually gay winter. The wedding will take place at high noon in the Epiphany Episcopal Church, with which the bride's

PRINCE GEORGE OF GREECE.

family is connected, and from which each of her three elder sisters has been married. It will be that most spectacular of all nuptials—a military wedding.

Miss Condit-Smith has been an undisputed belle in what is termed the court circle of Washington for several seasons. She comes from a family of more than ordinary distinction. She is the niece of the late Chief-Justice Field through her mother,

QUEEN WILHELMINA AND DUKE HEINRICH.



who is the sister of Mrs. Field. She has travelled extensively. A year ago she went to Japan to visit her sister, Mrs. Albert Key, wife of the military attaché of the American legation at Tokio. It was while making this visit that she accepted the invitation of Minister and Mrs. Conger to spend some time with them in the legation at Peking, and it was in this way that she came to be there during the recent Boxer outrages. Mrs. Condit-Smith has three daughters besides Miss Mary, all of whom are married and occupying high social positions. The eldest is Mrs. Cyrus Field Judson, of New York; the second is the wife of General Wood, military governor of Cuba; and the third is Mrs. Key. They are all handsome women, but Miss Mary, who is a tall, queenly girl of the blond

PRINCESS VICTORIA OF WALES.

type, and whose neck and shoulders are superb, is considered the greatest beauty.

The groom, Lieutenant Hooker, is the son of Mrs. Bessie Stewart, of Washington and New York, and the grandson of Senator W. M. Stewart, of Nevada. He met his bride while they were children in California.

GRAND DUKE MICHAEL OF RUSSIA.

TESLA'S WIRELESS LIGHT.

Nikola Tesla has given to The New York Sun an authorized statement concerning his new experiments on the production of light without the aid of wires. Mr. Tesla says:

"This light is the result of continuous efforts since my early experimental demonstrations before scientific societies here and abroad. In order to make it suitable for commercial use, I had to overcome great difficulties. One of these was to produce from ordinary currents of supply electrical oscillations of enormous rapidity in a simple and economical manner. This, I am glad to say, I have now accomplished, and the results show that with this new form of light a higher economy is practicable than with the present illuminants. The light offers, besides, many specific advantages, not the least of which is found in its hygienic properties. It is, I believe, the closest approach to daylight which has yet been reached from any artificial source.

"The lamps are glass tubes which may be bent in any ornamental way. I most generally use a rectangular spiral, containing about twenty to twenty-five feet of tubing making some twelve to fourteen convolutions. The total illuminating surface of a lamp is from 300 to 400 square inches. The ends of the spiral tube are covered with a metallic coating, and provided with hooks for hanging the lamp on the terminals of the source of oscillations. The tube contains gases rarefied to a certain degree, determined in the course of long experimentation as being conductive to the best results.

"The process of light production is, according to my views, as follows: The street current is passed through a machine which is an electrical oscillator of peculiar construction and transforms the supply current, be it direct or alternating, into electrical oscillations of a very high frequency. These oscillations, coming to the metallically-coated ends of the glass tube, produce in the interior corresponding electrical oscillations, which set the molecules and atoms of the inclosed rarefied gases into violent commotion, causing them to vibrate at enormous rates and emit those radiations which we know as light. The gases are not rendered incandescent in the ordinary sense, for if it were so, they would be hot, like an incandescent filament. As a matter of fact, there is very little heat noticeable, which speaks well for the economy of the light, since all heat would be loss.

"This high economy results chiefly from three causes: First, from the high rate of the electrical oscillations; second, from the fact that the entire light-giving body, being a highly attenuated gas, is exposed and can throw out its radiations unimpeded, and, third, because of the smallness of the particles composing the light-giving body, in consequence of which they can be quickly thrown into a high rate of vibration, so that comparatively little energy is lost in the lower or heat vibrations. An important practical advantage is that the lamps need not be renewed like the ordinary ones, as there is nothing in them to consume. Some of these lamps I have had for years, and they are now in just as good a condition as they ever were. The illuminating power of each of these lamps is, measured by the photometric method, about fifty candle power, but I can make them of any power desired, up to that of several arc lights. It is a remarkable feature of the light that during the day it can scarcely be seen, whereas at night the whole room is brilliantly illuminated. When the eye becomes used to the light of these tubes, an ordinary incandescent lamp or gas burner produces a violent pain in the eye when it is turned on, showing in a striking manner to what a degree these concentrated sources of light which we now use are detrimental to the eye.

"I have found that in almost all its actions the light produces the same effects as sunlight, and this makes me hopeful that its introduction into dwellings will have the effect of improving, in a measure now impossible to estimate, the hygienic conditions. Since sunlight is a very powerful curative agent, and since this light makes it possible to have sunlight, so to speak, of any desired intensity, day and night in our homes, it stands to reason that the development of germs will be checked and many diseases, as consumption, for instance, successfully combated by continually exposing the patients to the rays of these lamps. I have ascertained unmistakably that the light produces a soothing action on the nerves, which I attribute to the effect which it has upon the retina of the eye. It also improves vision, just exactly as the sunlight, and it ozonizes slightly the atmosphere. These effects can be regulated at will. For instance, in hospitals, where such a light is of paramount importance, lamps may be designed which will produce just that quantity of ozone which the physician may desire for the purification of the atmosphere, or if necessary, the ozone production can be stopped altogether.

"The lamps are very cheap to manufacture, and by the fact that they need not be exchanged like ordinary lamps or burners they are rendered still less expensive. The chief consideration is, of course, in commercial introduction, the energy consumption. While I am not yet prepared to give exact figures, I can say that, given a certain quantity of electrical energy from the mains, I can produce more light than can be produced by the ordinary methods. In introducing this system of lighting my transformer, or oscillator, will be usually located at some convenient place in the basement, and from there the transformed currents will be led as usual through the building. The lamps can be run with one wire alone, as I have shown in my early demonstrations, and in some cases I can dispense entirely with the wires. I hope that ultimately we shall get to this ideal form of illumination, and that we shall have in our rooms lamps which will be set aglow no matter where they are placed, just as an object is heated by heat rays emanating from a stove. The lamps will then be handled like kerosene lamps, with this difference, however, that the energy will be conveyed through space. The ultimate perfection of apparatus for the production of electrical oscillations will probably bring us to this great realization, and then we shall finally have the light without heat or 'cold' light. I have no difficulty now to illuminate the room with such wireless lamps, but a number of improvements must be made yet before it can be generally introduced."

Tesla's Vacuum-tube Lighting.

As is well known, Mr. Tesla has been engaged on experiments in vacuum-tube lighting for the last decade. According to the daily press, he has recently made a considerable advance in this direction. From one account the following statements are taken:

New York, January 26.—Nikola Tesla, who has been striving for years to produce an electric light without heat, feels that he is making perceptible headway in that undertaking. His general plan is to use an alternating current of almost inconceivably great frequency and a lamp consisting of a vacuum tube. The alternations are secured by an instrument of his own invention, known as the oscillator. But after Mr. Tesla entered upon his interesting line of experimenting he encountered various unforeseen difficulties. While he was able to obtain a beautiful light almost at the outset, it was at the expense of more energy than was desirable. In other words, he did not have his invention on a thoroughly satisfactory basis.

By degrees he has improved the efficiency of his apparatus so that his light is now more economical than it was, and he regards it as superior to both the incandescent and arc lights in this respect. At present, however, he is unwilling to indicate precisely the nature and degree of the technical advances made or to use figures in comparing its economy with that of its rivals. One reason for reticence on the latter point may be a recognition of the possibility of further improvement. Mr. Tesla frankly declares that his lamp is not yet perfect. It does not make as good a return in light for the electrical energy invested as he would like. All that he insists upon is that it is now so efficient that he can conscientiously recommend it to those who may wish to put it on the market.

In some of his earlier experiments Mr. Tesla used a straight vacuum tube fully an inch and a half in diameter and six or eight feet long. Latterly, he has employed a more slender one, and by arranging this tube in the shape of a rather compact coil he saves a great deal of space.

A score of lamps of this sort, each with a porcelain reflector over it, may be suspended from the ceilings of rooms on the tenth floor of an office building, while the special apparatus which modifies the current for their use would be down in the basement. The street mains would supply an ordinary alternating current and other wires would lead from the oscillator up to the lamps. For some purposes two wires to each lamp would be preferable, but for others one would suffice. Less copper would be required for inside wiring, and the risks from escaping currents would be diminished rather than increased. The present style of insulation would be more than sufficient.

NIKOLA TESLA Duplicates the LIGHT of DAY.

DESIGN FOR READING LAMP

MR. TESLA EXHIBITING HIS NEW LIGHT IN HIS LABRATORY

DIFFERENT STYLES OF LAMPS IN MR TESLA'S LABRATORY

WITHOUT WICK, WIRE OR CARBON FILAMENT THE INVENTOR'S NEW ELECTRIC LAMP SHEDS THE RADIANCE OF MORNING—IS THE PRODUCT OF TESLA'S FAMOUS OSCILLATOR—A SOFT, WHITE, COLORLESS LIGHT WITHOUT HEAT—THE LAMP A BABY SUN—WONDROUS SANITARY QUALITIES ATTRIBUTED TO THE NEW ILLUMINATOR. . . . . .

WITH the new century come new discoveries. Remarkable interest is now awakened by Tesla's new light. "Artificial sunlight," he calls it, "the result of ten years of thought and experiment."

Under a full head of electricity the lamp presents a magic spectacle. Without wick, wire or carbon filament it floods an apartment with the light of day. It is soothing to the eye and wonderfully diffused—almost shadowless. In its soft radiance one may read and write in any corner of the room as if it were day.

And how is this light produced?

By electrical vibrations of tremendous speed. For years the public has heard of Tesla's oscillator—that wonderful machine roaring out lightning in zigzag leaping tongues of flame, which Tesla claimed was to produce wonders, such as sending currents around the world without wires and burning the nitrogen of the air.

A thousand times it was asked, "Of what practical use is such a machine?"

One of the answers to this question is this daylight illumination.

His oscillator, the inventor says, is the key to solving the most important problems of the age. By its vibrations this new radiance is produced, as from the sun, its pulsations amounting to millions per second.

The electrical vibrations of the oscillator cause the atoms of the gases in Tesla's lamp to become little comets, shooting through the space at enormous speed, leaving trains of light filling the lamp with the brightness of noon.

It is a miracle, seemingly. The sudden starting and stopping of the electrical current at inconceivable velocity produce a continuous glow, neither of the incandescent nor arc light character, but pure solar light, the light of day.

THE OSCILLATOR EXPLAINED.

How does the oscillator accomplish this wonder? Simply by storing and discharging alternately, electricity. An instrument called a "condenser" is used for this purpose. According to Tesla, it is the most marvellous appliance ever invented.

"It can discharge," he says, "or explode its stored energy in an inconceivably short time. Owing to this it is unequalled in explosive violence. The explosion of dynamite is only the breath of a consumptive compared with its discharge. It is the means of producing the strongest current, the highest electrical pressure, the greatest commotion in the medium. Another of its properties equally valuable is that its discharge may vibrate at any rate desired up to many millions per second.

"I arranged such an instrument so as to be charged and discharged alternately in rapid succession through a coil with a few turns of stout wire, forming the primary of a transformer or induction coil. Each time the condenser was discharged the current would quiver in the primary wire and induce corresponding oscillations in the secondary. Thus a transformer or induction coil on new principles was evolved, which I have called the electrical oscillator, partaking of those unique qualities which characterize the condenser and enabling results to be attained impossible by other means."

Such is the much discussed machine of Tesla's, which, he claims, will accomplish many more wonders in light, telegraphy, telephony and the transmission of power, and set up vibrations and electric wave currents pervading the universe of matter, and perhaps entering a new world hitherto penetrated only by the imagination.

HOW THE LIGHT IS MADE

Regarding his new system of illumination, Tesla says:—"The light is the result of continuous efforts since my early experimental demonstrations before scientific societies here and abroad. In order to make it suitable for commercial use, I had to overcome great difficulties. One of these was to produce from ordinary currents of supply electrical oscillations of enormous rapidity in a simple and economical manner. This, I am glad to say, I have now accomplished, and the results show that with this new form of light a higher economy is practicable than with the present illuminants. The light offers, besides, many specific advantages, not the least of which is found in its hygienic properties. It is, I believe, the closest approach to daylight which has yet been reached from any artificial source."

Tesla's lamps are tubes of glass of the size of one's finger. They may be bent in any ornamental fashion—in spirals, expanding circles, rectangular clusters and the like. He says:—

"I generally use a rectangular spiral, containg about twenty to twenty-five feet of tubing, making some twelve to fourteen convolutions. The total illuminating surface of a lamp is from three hundred to four hundred square inches. The ends of the spiral tubes are covered with metallic coating and provided with hooks for hanging the lamp on the terminals of the source of oscillations. The tube contains gases rarefied to a certain degree, determined in the course of long experimentation as being conducive to the best results."

ILLUMINATION WITHOUT HEAT.

Here is a technical but plain description in Tesla's own words of how the light is produced:—

"The street current is passed through a machine which is an electrical oscillator of peculiar construction, and transforms the supply current, be it direct or alternating, into electrical oscillations of a very high frequency.

"These oscillations, coming to the metallically coated ends of the glass tube, produce in the interior corresponding electrical oscillations, which set the molecules and atoms of the enclosed rarefied gases into violent commotion, causing them to vibrate at enormous rates and emit those radiations which we know as light.

"The gases are not rendered incandescent in the ordinary sense, for were it so, they would be hot, like an incandescent filament. As a matter of fact, there is very little heat noticeable, which speaks well for the economy of the light, since all heat would be loss.

"This high economy results chiefly from three causes:—First from the high rate of the electrical oscillations; second, from the fact that the entire light-giving body, being a highly attenuated gas, is exposed and can throw out its radiations unimpeded, and, third, because of the smallness of the particles composing the light-giving body, in consequence of which they can be quickly thrown into a high rate of vibration, so that comparatively little energy is lost in the lower or heat vibrations."

NO WIRES OR CARBONS.

One great disadvantage in using electrical lamps has been breakage. The carbon filaments are sometimes defective, often short lived and more or less of a nuisance. Tesla has no filaments to become incandescent, neither carbons nor wires. Thus an important point is gained. He says:—

"The lamps need not be renewed like the ordinary ones, as there is nothing in them to consume. Some of these lamps I have had for years, and they are now in just as good a condition as they ever were.

"The illuminating power of each of these lamps is, measured by the photometric method, about fifty candle power, but I can make them of any power desired up to that of several arc lights. It is a remarkable feature of the light that during the day it can scarcely be seen, whereas at night the whole room is brilliantly illuminated.

"When the eye becomes used to the light of these tubes, an ordinary incandescent lamp or gas burner produces a violent pain in the eye when it is turned on, showing in a striking manner to what degree these concentrated sources of light which we now use are detrimental to the eye."

"A SANITARY LIGHT."

Regarding the sanitary features of the light, Tesla says:—

"I have found that in almost all its actions the light produces the same effects as sunlight, and this makes me hopeful that its introduction into dwellings will have the effect of improving, in a measure now impossible to estimate, the hygienic conditions.

"Since sunlight is such a very powerful curative agent, and since this light makes it possible to have sunlight, so to speak, of any desired intensity, day and night in our homes, it stands to reason that the development of germs will be checked and many diseases, as consumption, for instance, successfully combated by continually exposing the patients to the rays of these lamps.

"I have ascertained unmistakably that the light produces a soothing action on the nerves, which I attribute to the effect which it has upon the retina of the eye. It also improves vision, just exactly as the sunlight, and it ozonizes slightly the atmosphere.

"These effects can be regulated at will. For instance, in hospitals, where such a light is of paramount importance, lamps may be designed which will produce just that quantity of ozone which the physician may desire for the purification of the atmosphere, or if necessary, the ozone production can be stopped altogether."

As to the cost of these lamps, Tesla says:—

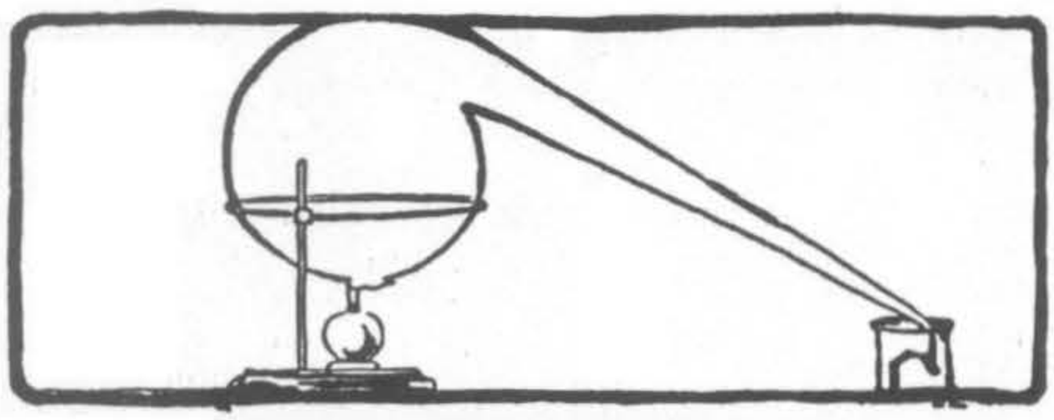
"The lamps are very cheap to manufacture, and by the fact that they need not be exchanged like ordinary lamps or burners they are rendered still less expensive. The chief consideration is, of course, in commercial introduction, the energy consumption. While I am not yet prepared to give exact figures, I can say that, given a certain quantity of electrical energy from the mains, I can produce more light than can be produced by the ordinary methods.

"In introducing this system of lighting my transformer, or oscillator, will be usually located at some convenient place in the basement, and from there the transformed currents will be led as usual through the building.

"The lamps can be run with one wire alone, as I have shown in my early demonstrations, and in some cases I can dispense entirely with the wires.

"I hope that ultimately we shall get to this ideal form of illumination, and that we shall have in our rooms lamps which will be set aglow, no matter where they are placed, just as an object is heated by heat rays emanating from a stove. The lamps will then be handled like kerosene lamps, with this difference, however, that the energy will be conveyed through space.

"The ultimate perfection of apparatus for the production of electrical oscillations will probably bring us to this great realization, and then we shall finally have the light without heat, of 'cold' light. I have no difficulty now in illuminating the room with such wireless lamps, but a number of improvements must be made yet before it can be generally introduced."



BABY SUNS AND DAYLIGHT.

In conclusion one may say of this strange all pervading crystal radiance of Tesla's that each lamp is a little baby sun filling the room with the flaming magic of life and health, the same that floods the solar system, making animal and vegetable existence possible on our earth.

As the lamps are lighted at evening you see dawn stealing over the room. It is like early morning. So perfect is the illusion that the change does not come instantly, but gradually, every corner growing brighter. Dark nooks fade out. Books, pictures and figures on walls and carpets, appear—their colors in natural shades, as at noonday.

Because of this wonderful artificial sunlight you now think the lamps may be extinguished. Day has indeed come—each moment it grows lighter. So out go the lamps.

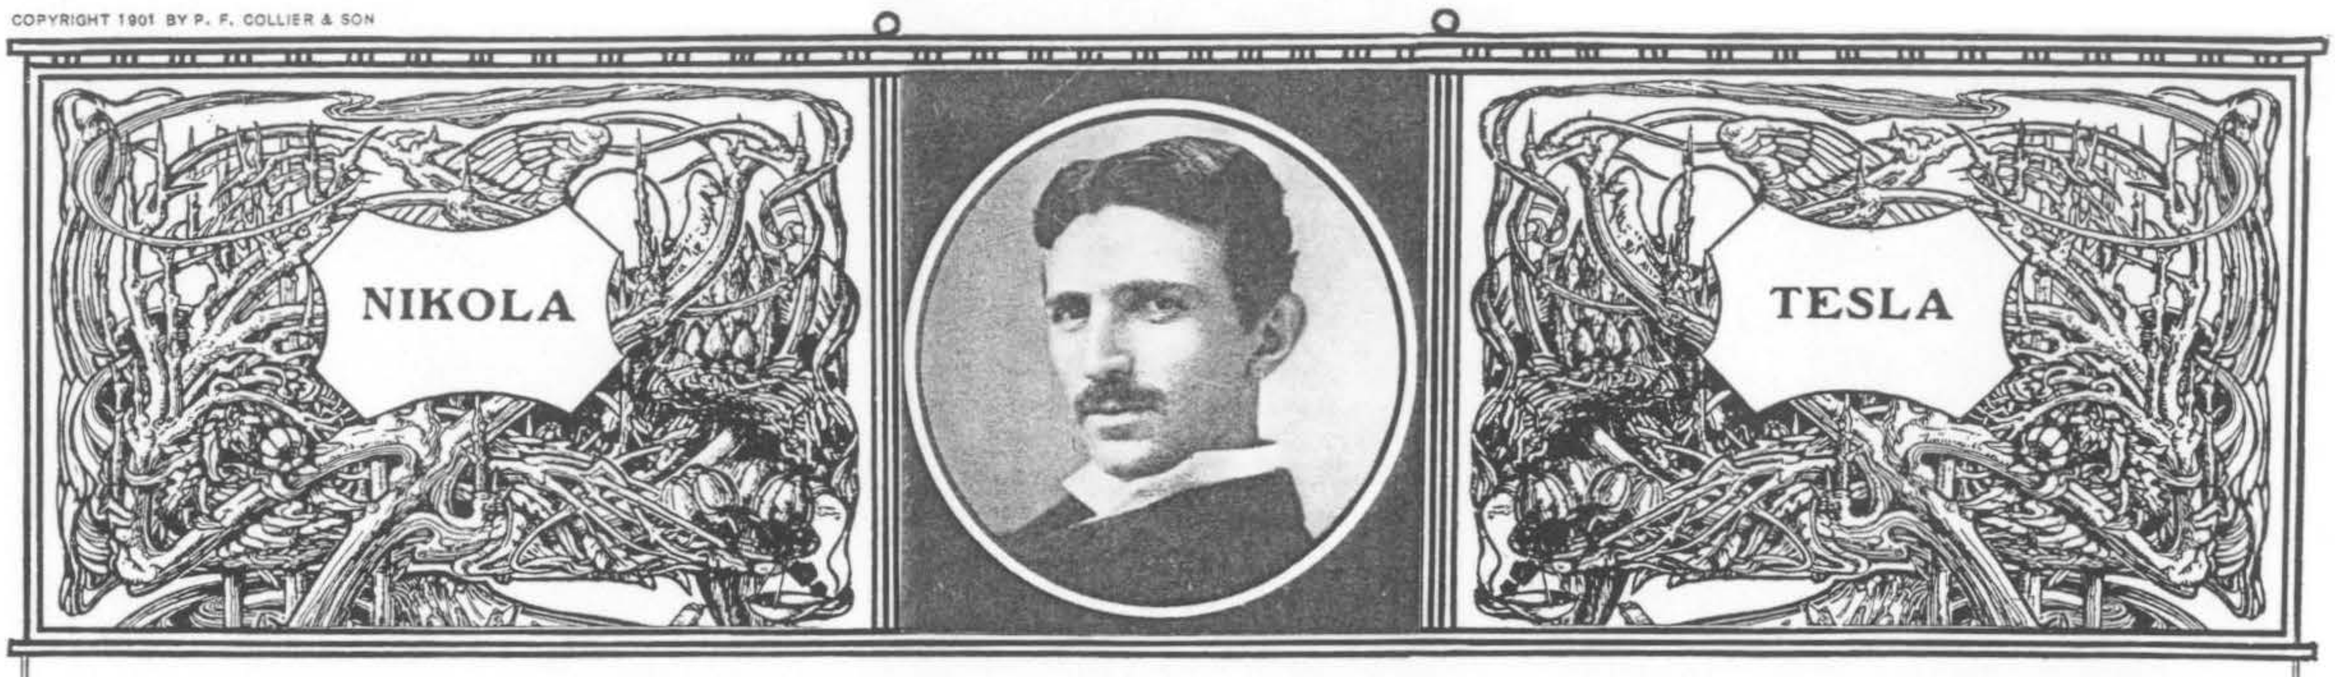
Alas! your room is in darkness, and you see the streets dusky in the yellow glare of the city's night. But if you light the lamps again the dawn reappears, and again morning has come.

SCIENTIFIC

Tesla's "Artificial Sunshine"

Nikola Tesla gave to the New York *Sun*, last week, an authorized statement in reference to his new light, described the lamp which diffuses the light, and then, darkening the windows of his laboratory in East Houston street, turned on an electric current, and in a moment the rooms were flooded with what Tesla calls "artificial sunshine." The light was diffused through a spiral of glass about eight inches high and six inches wide. The spiral is of glass tubing, about one-quarter of an inch in diameter, the ends being blown to about double the size of the tube and closely resembling wax candles. The general effect of the lamp is that of a small box made of glass tubing with two candles lying on their sides along the top. The ends of the spiral, which resemble candles, are covered with a thin coating of metal and painted white. The lamp illuminates whether it is connected by wires with an electric current or not. Mr. Tesla operates it with and without wires. The wonderful thing about the wireless lamp is that it may be carried about from one part of a room to another, picked up and set down at will, just as one would carry a kerosene lamp around, and all the time there is not so much as a flicker.

But more than all this, Mr. Tesla asserts that in discovering this process of illumination he has discovered a light which will be of incalculable value in the sick room and in the hospital ward. The tube of the lamp, before being closed at one end, is partly filled with certain gases, the properties of which Mr. Tesla is not quite ready to disclose, but which, he says, will purify the air of a sick room when it might endanger the life of the patient to have the windows opened, so that the room's atmosphere will be as pure as if the room had been flooded with outer air. The inventor asserts that so perfect is his invention that the "ozonizing" of a room, as he calls it, may be continued as long as desired and stopped at will. Tesla says that his artificial sunshine, or his "sanitary light," is intended to be his first gift to the new century, the practical result of years of experiment in the old.



"The lamps," Mr. Tesla said, "are glass tubes which may be bent in any ornamental way. I most generally use a rectangular spiral, containing about twenty to twenty-five feet of tubing, making some twelve to fourteen convolutions. The total illuminating surface of a lamp is from 300 to 400 square inches. The ends of the spiral tube are covered with a metallic coating and provided with hooks for hanging the lamp on the terminals of the source of oscillations. The tube contains gases rarified to a certain degree, determined in the course of long experimentation as being conducive to the best results.

"The process of light production is, according to my views, as follows: The street current is passed through a machine which is an electrical oscillator of peculiar construction and transforms the supply current, be it direct or alternating, into electrical oscillations of a very high frequency. These oscillations, coming to the metallically coated ends of the glass tube, produce in the interior corresponding electrical oscillations, which set the molecules and atoms of the inclosed rarefied gases into violent commotion, causing them to vibrate at enormous rates and emit those radiations which we know as light. The gases are not rendered incandescent in the ordinary sense, for if it were so, they would be hot, like an incandescent filament. As a matter of fact, there is very little heat noticeable, which speaks well for the economy of the light, since all heat would be loss.

"I have found that in almost all its actions the light produces the same effects as sunlight, and this makes me hopeful that its introduction into dwellings will have the effect of improving, in a measure now impossible to estimate, the hygienic conditions. Since sunlight is a very powerful curative agent, and since this light makes it possible to have sunlight, so to speak, of any desired intensity, day and night in our homes, it stands to reason that the development of germs will be checked and many diseases, as consumption for instance, successfully combatted by continually exposing the patients to the rays of these lamps. I have ascertained unmistakably that the light produces a soothing action on the nerves, which I attribute to the effect which it has upon the retina of the eye. It also improves vision, just exactly as the sunlight, and it ozonizes slightly the atmosphere. These effects can be regulated at will. For instance, in hospitals, where such a light is of paramount importance, lamps may be designed which will produce just that quantity of ozone which the physician may desire for the purification of the atmosphere, or if necessary, the ozone production can be stopped altogether.

"The lamps are very cheap to manufacture, and by the fact that they need not be exchanged like ordinary lamps or burners, they are rendered still less expensive. The chief consideration is, of course, in commercial introduction, the energy consumption. While I am not yet prepared to give exact figures, I can say that, given a certain quantity of electrical energy from the mains, I can produce more light than can be produced by the ordinary methods. But a number of improvements must be made before it can be generally introduced."

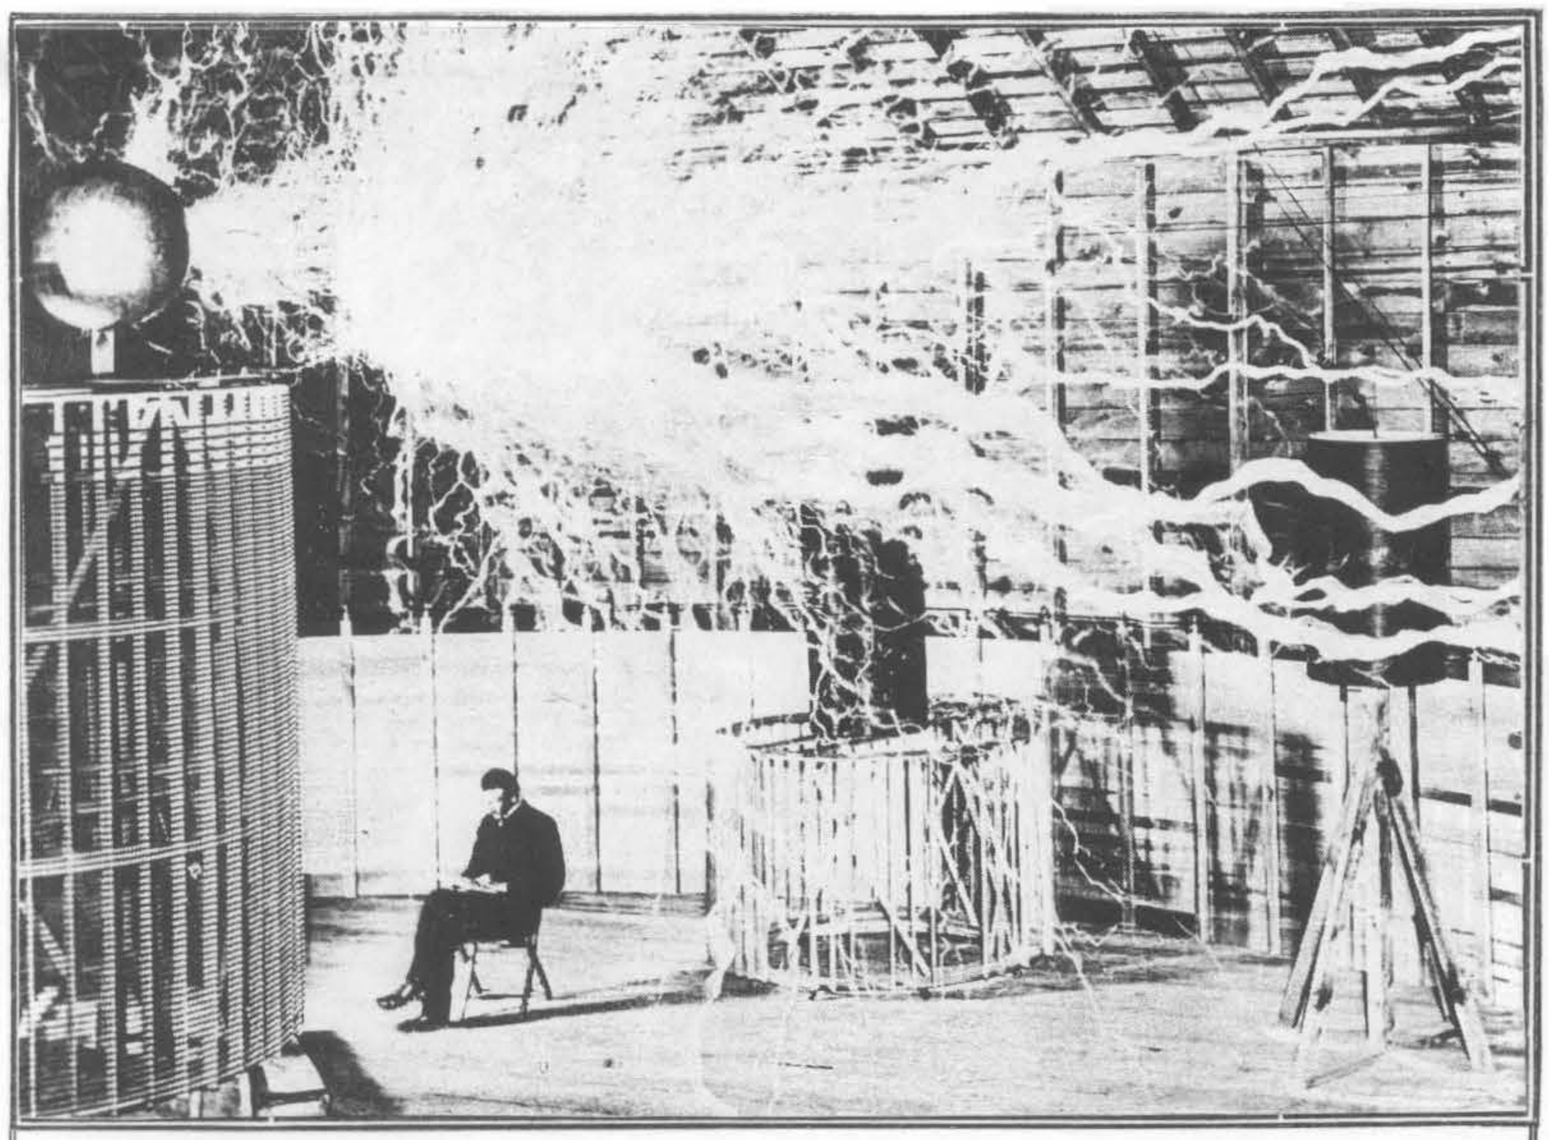
TALKING WITH THE PLANETS

By NIKOLA TESLA

EDITOR'S NOTE.—*Mr. Nikola Tesla has accomplished some marvellous results in electrical discoveries. Now, with the dawn of the new century, he announces an achievement which will amaze the entire universe, and which eclipses the wildest dream of the most visionary scientist. He has received communication, he asserts, from out the great void of space; a call from the inhabitants of Mars, or Venus, or some other sister planet! And, furthermore, noted scientists like Sir Norman Lockyer are disposed to agree with Mr. Tesla in his startling deductions.*

Mr. Tesla has not only discovered many important principles, but most of his inventions are in practical use; notably in the harnessing of the Titanic forces of Niagara Falls, and the discovery of a new light by means of a vacuum tube. He has, he declares, solved the problem of telegraphing without wires or artificial conductors of any sort, using the earth as his medium. By means of this principle he expects to be able to send messages under the ocean, and to any distance on the earth's surface. Interplanetary communication has interested him for years, and he sees no reason why we should not soon be within talking distance of Mars or of all worlds in the solar system that may be tenanted by intelligent beings.



At the request of COLLIER'S WEEKLY *Mr. Tesla presents herewith a frank statement of what he expects to accomplish and how he hopes to establish communication with the planets.*

THE IDEA of communicating with the inhabitants of other worlds is an old one. But for ages it has been regarded merely as a poet's dream, forever unrealizable. And yet, with the invention and perfection of the telescope and the ever-widening knowledge of the heavens, its hold upon our imaginations has been increased, and the scientific achievements during the latter part of the nineteenth century, together with the development of the tendency toward the nature ideal of Goethe, have intensified it to such a degree that it seems as if it were destined to become the dominating idea of the century that has just begun. The desire to know something of our neighbors in the immense depths of space does not spring from idle curiosity nor from thirst for knowledge, but from a deeper cause, and it is a feeling firmly rooted in the heart of every human being capable of thinking at all.

Whence, then, does it come? Who knows? Who can assign limits to the subtlety of nature's influences? Perhaps if we could clearly perceive all the intricate mechanism of the glorious spectacle that is continually unfolding before us, and could, also, trace this desire to its distant origin, we might find it in the sorrowful vibrations of the earth which began when it parted from its celestial parent.

But in this age of reason it is not astonishing to find persons who scoff at the very thought of effecting communication with a planet. First of all, the argument is made that there is only a small probability of other planets being inhabited at all. This argument has never appealed to me. In the solar system, there seem to be only two planets—Venus and Mars—capable of sustaining life such as ours; but this does not mean that there might not be on all of them some other forms of life. Chemical processes may be maintained without the aid of oxygen, and it is still a question whether chemical processes are absolutely necessary for the sustenance of organized beings. My idea is that the development of life must lead to forms of existence that will be possible without nourishment and which will not be shackled by consequent limitations. Why should a living being not be able to obtain all the energy it needs for the performance of its life-functions from the environment, instead of through consumption of food, and transforming, by a complicated process, the energy of chemical combinations into life-sustaining energy?

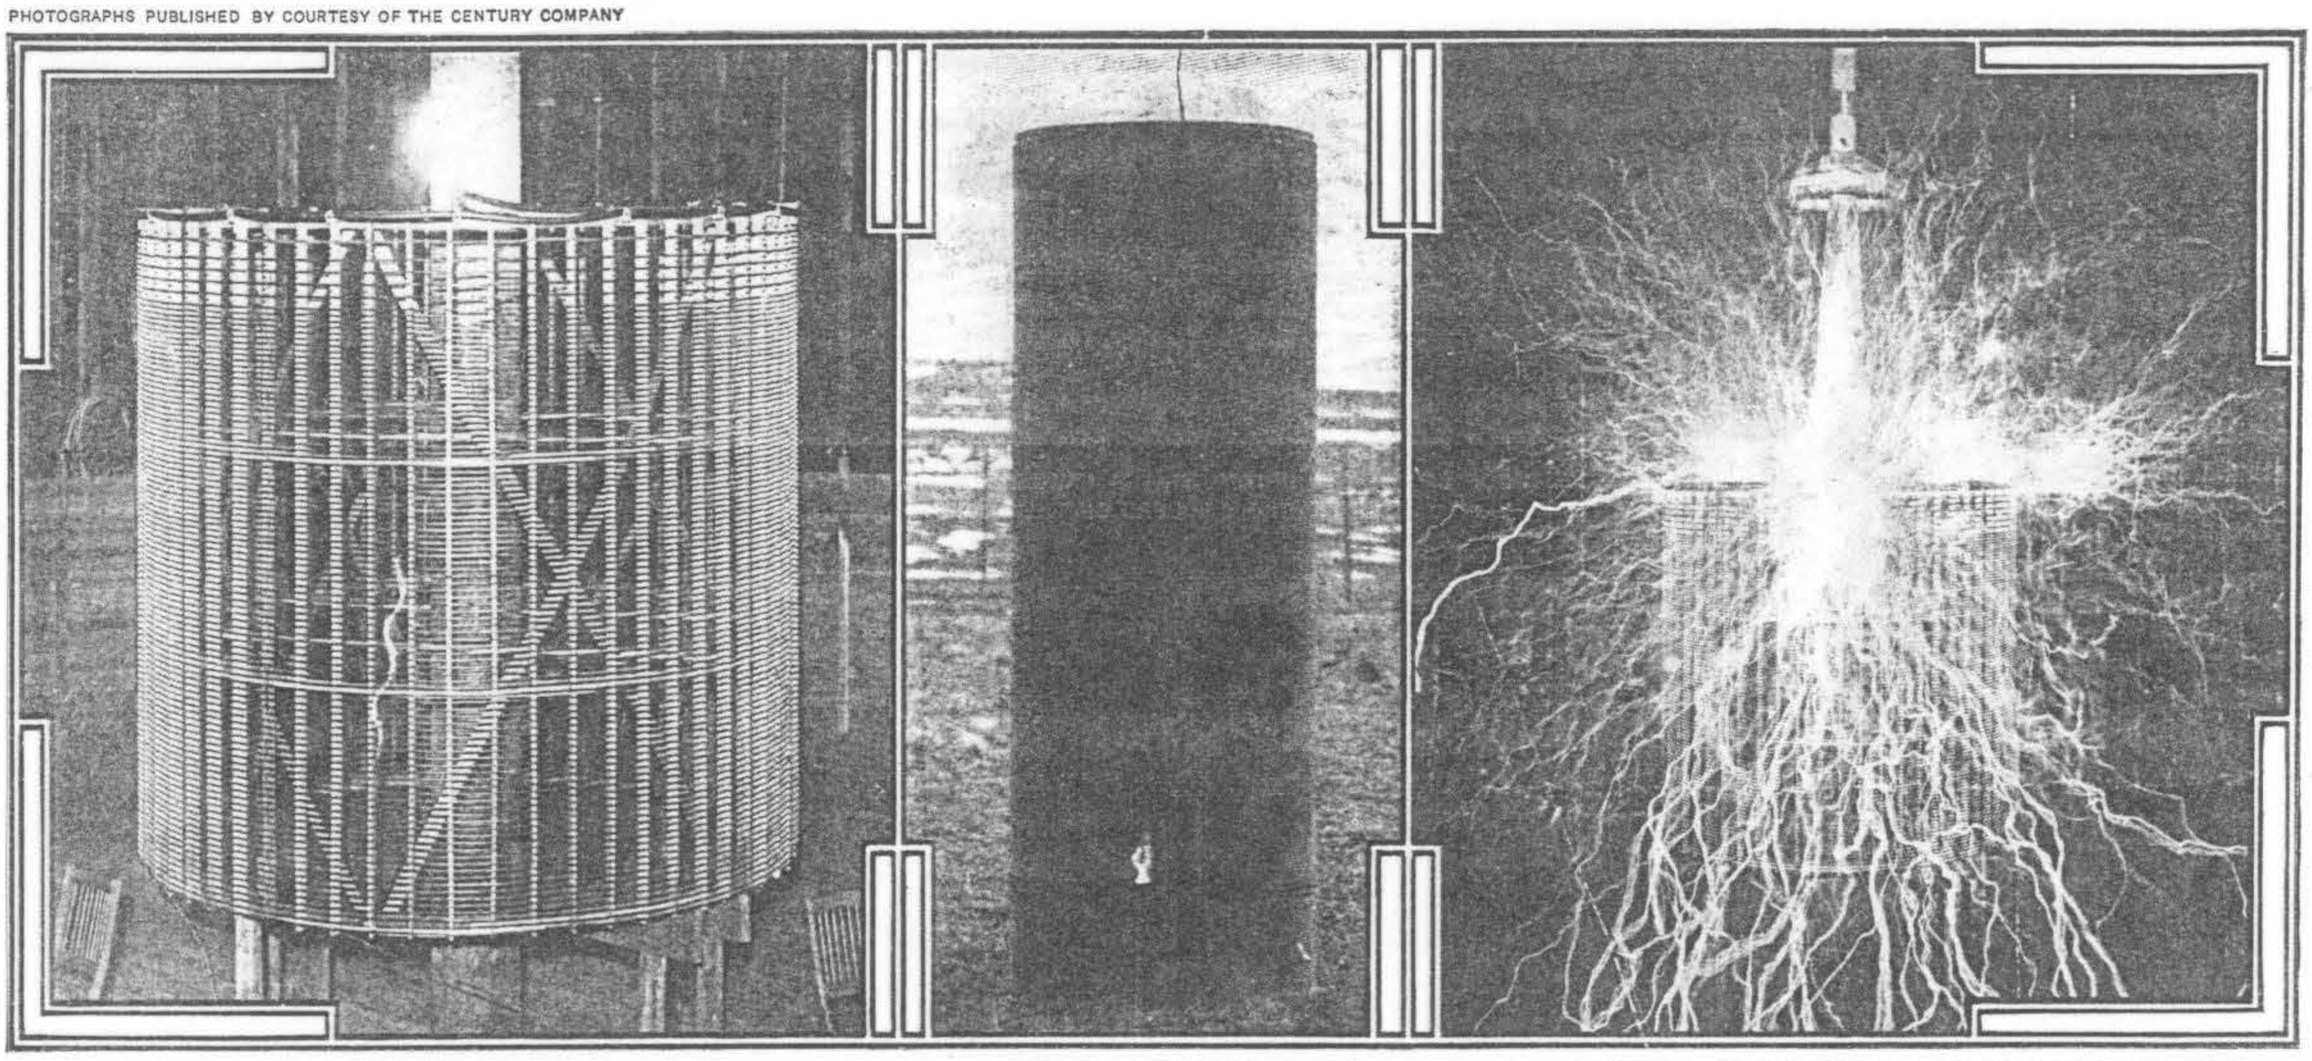
If there were such beings on one of the planets we should know next to nothing about them. Nor is it necessary to go so far in our assumptions, for we can readily conceive that, in the same degree as the atmosphere diminishes in density, moisture disappears and the planet freezes up, organic life might also undergo corresponding modifications, leading finally to forms which, according to our present ideas of life, are impossible. I will readily admit, of course, that if there should be a sudden catastrophe of any kind all life processes might be arrested; but if the changes, no matter how great, should be gradual, and occupied ages, so that the ultimate results could be intelligently foreseen, I cannot but think that reasoning beings would still find means of existence. They would adapt themselves to their constantly changing environment. So I think it quite possible that in a frozen planet, such as our moon is supposed to be, intelligent beings may still dwell, in its interior, if not on its surface.

MR. TESLA'S EXPERIMENT TO ILLUSTRATE THE CAPACITY OF HIS OSCILLATOR FOR PRODUCING ELECTRICAL EXPLOSIONS OF GREAT POWER

SIGNALLING AT 100,000,000 MILES!

Then it is contended that it is beyond human power and ingenuity to convey signals to the almost inconceivable distances of fifty million or one hundred million miles. This might have been a valid argument formerly. It is not so now. Most of those who are enthusiastic upon the subject of interplanetary communication have reposed their faith in the light-ray as the best possible medium of such communication. True, waves of light, owing to their immense rapidity of succession, can penetrate space more readily than waves less rapid, but a simple consideration will show that by their means an exchange of signals between this earth and its companions in the solar system is, at least now, impossible. By way of illustration, let us suppose that a square mile of the earth's surface—the smallest area that might possibly be within reach of the best telescopic vision of other worlds—were covered with incandescent lamps, packed closely together so as to form, when illuminated, a continuous sheet of light. It would require not less than one hundred million horse-power to light this area of lamps, and this is many times the amount of motive power now in the service of man throughout the world.

But with the novel means, proposed by myself, I can readily demonstrate that, with an expenditure not exceeding two thousand horse-power, signals can be transmitted to a planet such as Mars with as much exactness and certitude as we now send messages by wire from New York to Philadelphia. These means are the result of long-continued experiment and gradual improvement.



Some ten years ago, I recognized the fact that to convey electric currents to a distance it was not at all necessary to employ a return wire, but that any amount of energy might be transmitted by using a single wire. I illustrated this principle by numerous experiments, which, at that time, excited considerable attention among scientific men.

This being practically demonstrated, my next step was to use the earth itself as the medium for conducting the currents, thus dispensing with wires and all other artificial conductors. So I was led to the development of a system of energy transmission and of telegraphy without the use of wires, which I described in 1893. The difficulties I encountered at first in the transmission of currents through the earth were very great. At that time I had at hand only ordinary apparatus, which I found to be ineffective, and I concentrated my attention immediately upon perfecting machines for this special purpose. This work consumed a number of years, but I finally vanquished all difficulties and succeeded in producing a machine which, to explain its operation in plain language, resembled a pump in its action, drawing electricity from the earth and driving it back into the same at an enormous rate, thus creating ripples or disturbances which, spreading through the earth as through a wire, could be detected at great distances by carefully attuned receiving circuits. In this manner I was able to transmit to a distance, not only feeble effects for purposes of signalling, but considerable amounts of energy, and later discoveries I made convinced me that I shall ultimately succeed in conveying power without wires, for industrial purposes, with high economy, and to any distance, however great.

EXPERIMENTS IN COLORADO

To develop these inventions further, I went to Colorado in 1899, where I continued my investigations along these and other lines, one of which in particular I now consider of even greater importance than the transmission of power without wires. I constructed a laboratory in the neighborhood of Pike's Peak. The conditions in the pure air of the Colorado Mountains proved extremely favorable for my experiments, and the results were most gratifying to me. I found that I could not only accomplish more work, physically and mentally, than I could in New York, but that electrical effects and changes were more readily and distinctly perceived. A few years ago it was virtually impossible to produce electrical sparks twenty or thirty feet long; but I produced some more than one hundred feet in length, and this without difficulty. The rates of electrical movement involved in strong induction

TRANSMITTING ELECTRICAL ENERGY THROUGH THE EARTH WITHOUT WIRE

AN ELECTRICAL OSCILLATOR DELIVERING ENERGY AT A RATE OF 75,000 HORSE-POWER

apparatus had measured but a few hundred horse-power, and I produced electrical movements of rates of one hundred and ten thousand horse-power. Prior to this, only insignificant electrical pressures were obtained, while I have reached fifty million volts.

The accompanying illustrations, with their descriptive titles, taken from an article I wrote for the "Century Magazine," may serve to convey an idea of the results I obtained in the directions indicated.

Many persons in my own profession have wondered at them and have asked what I am trying to do. But the time is not far away now when the practical results of my labors will be placed before the world and their influence felt everywhere. One of the immediate consequences will be the transmission of messages without wires, over sea or land, to an immense distance. I have already demonstrated, by crucial tests, the practicability of signalling by my system from one to any other point of the globe, no matter how remote, and I shall soon convert the disbelievers.

I have every reason for congratulating myself that throughout these experiments, many of which were exceedingly delicate and hazardous, neither myself nor any of my assistants received an injury. When working with these powerful electrical oscillations the most extraordinary phenomena take place at times. Owing to some interference of the oscillations, veritable balls of fire are apt to leap out to a great distance, and if any one were within or near their paths, he would be instantly destroyed. A machine such as I have used could easily kill, in an instant, three hundred thousand persons. I observed that the strain upon my assistants was telling, and some of them could not endure the extreme tension of the nerves. But these perils are now entirely overcome, and the operation of such apparatus, however powerful, involves no risk whatever.

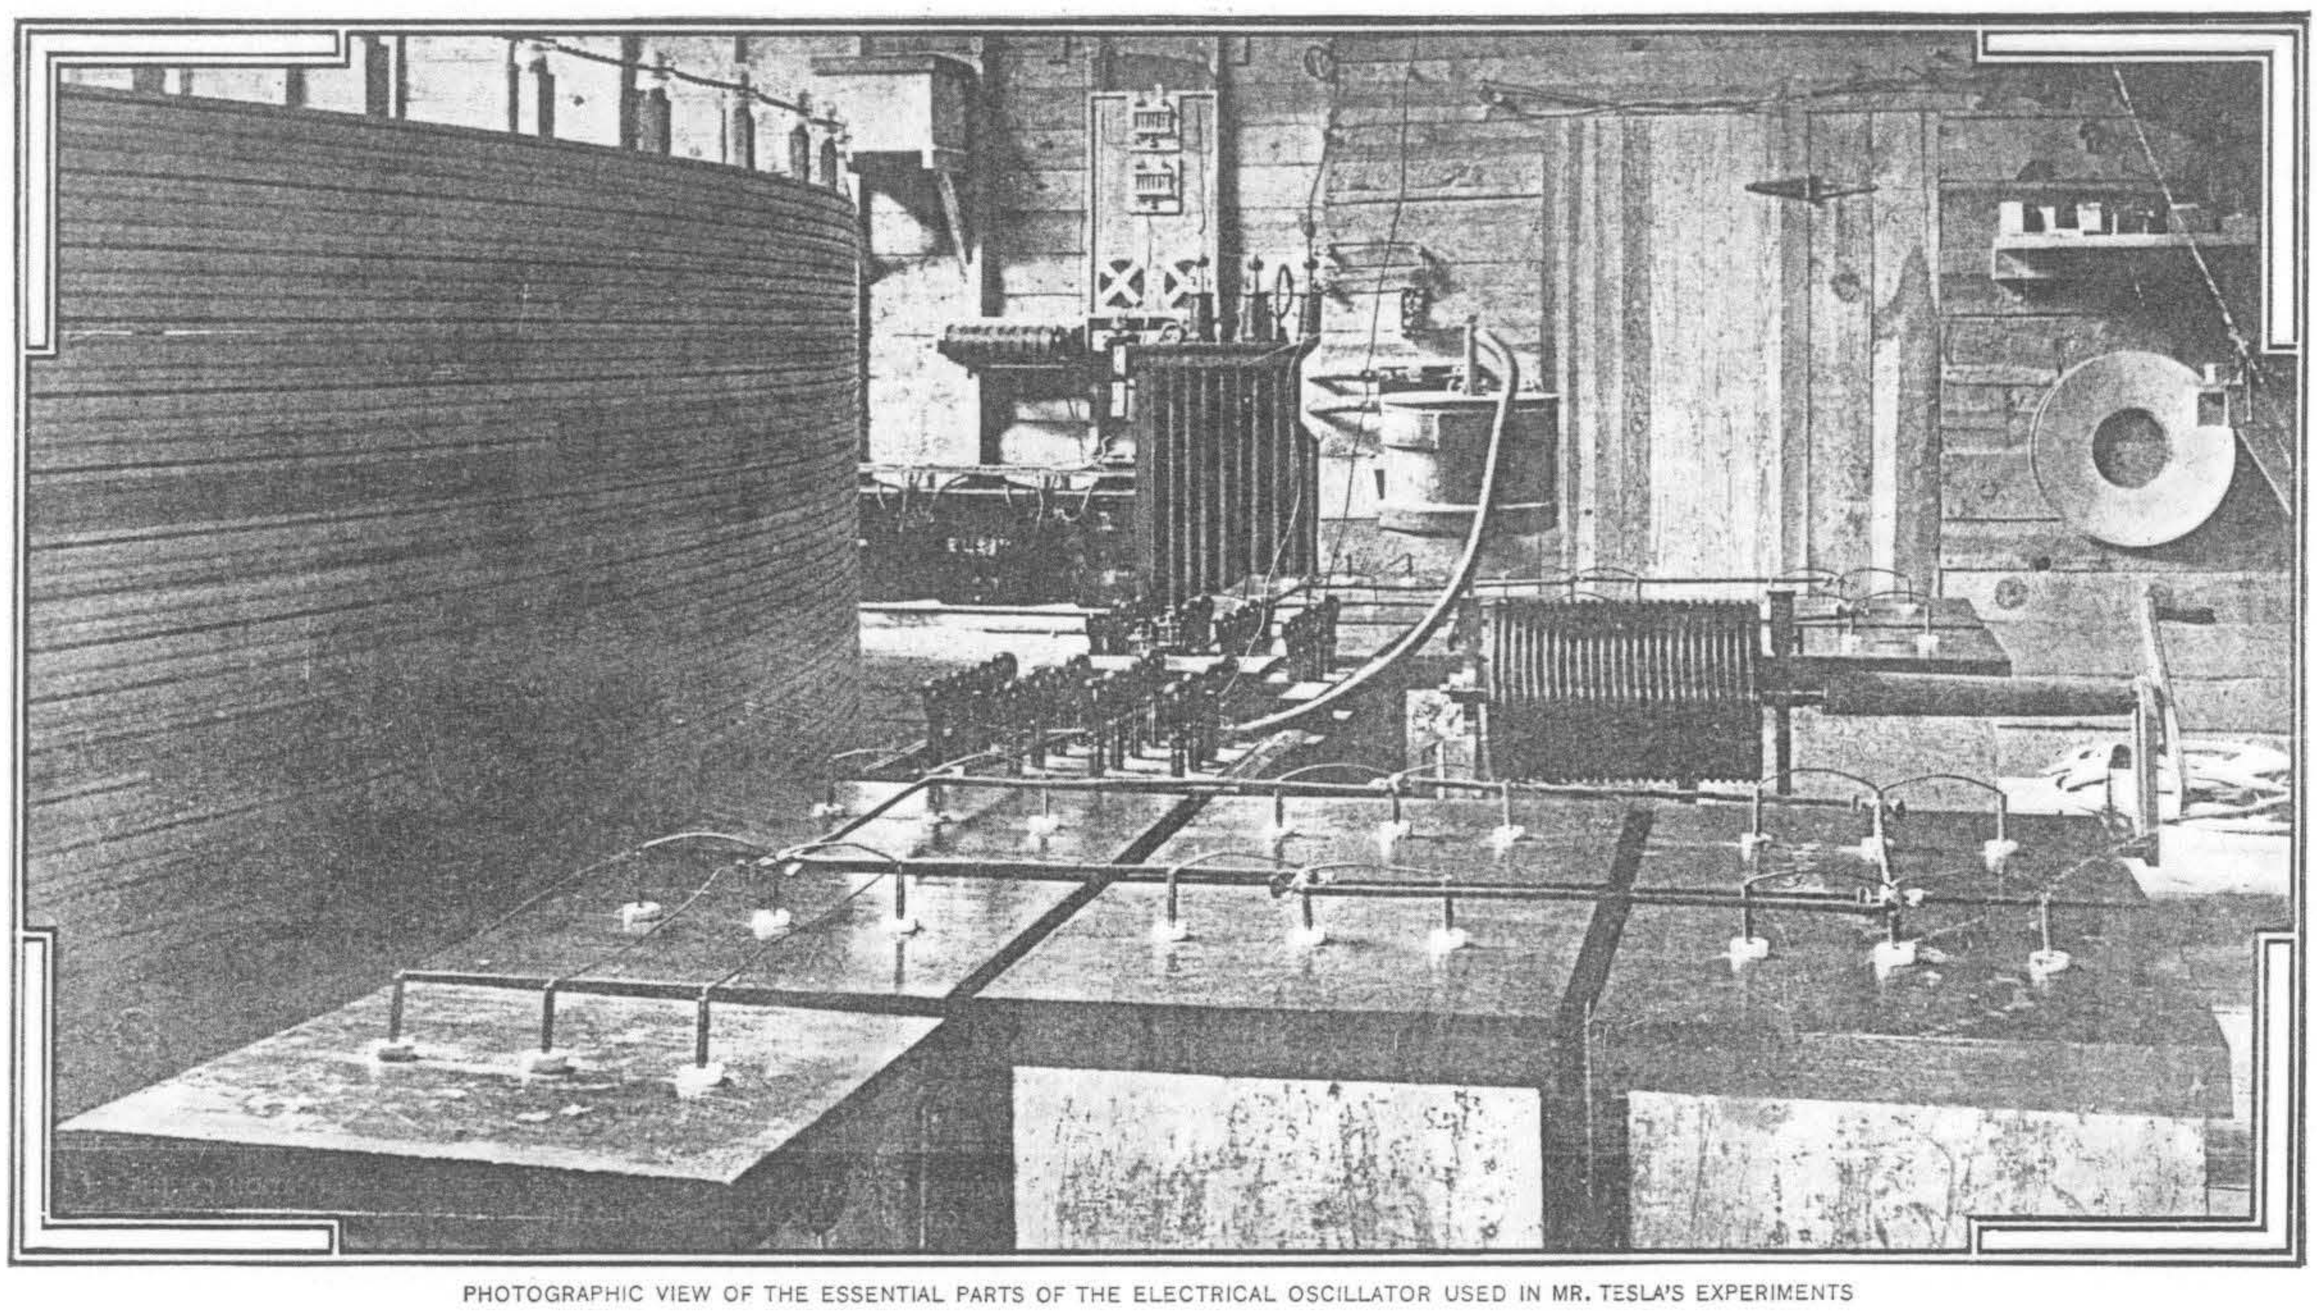
As I was improving my machines for the production of intense electrical actions, I was also perfecting the means for observing feeble effects. One of the most interesting results, and also one of great practical importance, was the development of certain contrivances for indicating at a distance of many hundred miles an approaching storm, its direction, speed and distance travelled. These appliances are likely to be valuable in future meteorological observations and surveying, and will lend themselves particularly to many naval uses.

It was in carrying on this work that for the first time I discovered those mysterious effects which have elicited such unusual interest. I had perfected the apparatus referred to so far that from my laboratory in the Colorado mountains I could feel the pulse of the globe, as it were, noting every electrical change that occurred within a radius of eleven hundred miles.

TERRIFIED BY SUCCESS

I can never forget the first sensations I experienced when it dawned upon me that I had observed something possibly of incalculable consequences to mankind. I felt as though I were present at the birth of a new knowledge or the revelation of a great truth. Even now, at times, I can vividly recall the incident, and see my apparatus as though it were actually before me. My first observations positively terrified me, as there was present in them something mysterious, not to say supernatural, and I was alone in my laboratory at night; but at that time the idea of these disturbances being intelligently controlled signals did not yet present itself to me.

The changes I noted were taking place periodically, and with such a clear suggestion of number and order that they were not traceable to any cause then known to me. I was familiar, of course, with such electrical disturbances as are produced by the sun, Aurora Borealis and earth currents, and I was as sure as I could be of any fact that these variations were due to none of these causes. The nature of my experiments precluded the possibility of the changes being produced by atmospheric disturbances, as has been rashly asserted by some. It was some time afterward when the thought flashed upon my mind that the disturbances I had observed might be due to an intelligent control. Although I could not decipher their meaning, it was impossible for me to think of them as having been entirely accidental. The feeling is constantly growing on me that I had been the first to hear the greeting of one planet to another. A purpose was behind these electrical signals; and it was with this conviction that I announced to the Red Cross Society, when it asked me to indicate one of the great possible achievements of the next hundred years, that it would probably be the confirmation and interpretation of this planetary challenge to us.



Since my return to New York more urgent work has consumed all my attention; but I have never ceased to think of those experiences and of the observations made in Colorado. I am constantly endeavoring to improve and perfect my apparatus, and just as soon as practicable I shall again take up the thread of my investigations at the point where I have been forced to lay it down for a time.

COMMUNICATING WITH THE MARTIANS

At the present stage of progress, there would be no insurmountable obstacle in constructing a machine capable of conveying a message to Mars, nor would there be any great difficulty in recording signals transmitted to us by the inhabitants of that planet, if they be skilled electricians. Communication once established, even in the simplest way, as by a mere interchange of numbers, the progress toward more intelligible communication would be rapid. Absolute certitude as to the receipt and interchange of messages would be reached as soon as we could respond with the number "four," say, in reply to the signal "one, two, three." The Martians, or the inhabitants of whatever planet had signalled to us, would understand at once that we had caught their message across the gulf of space and had sent back a response. To convey a knowledge of form by such means is, while very difficult, not impossible, and I have already found a way of doing it.

What a tremendous stir this would make in the world! How soon will it come? For that it will some time be accomplished must be clear to every thoughtful being.

Something, at least, science has gained. But I hope that it will also be demonstrated soon that in my experiments in the West I was not merely beholding a vision, but had caught sight of a great and profound truth.

PHOTOGRAPHIC VIEW OF THE ESSENTIAL PARTS OF THE ELECTRICAL OSCILLATOR USED IN MR. TESLA'S EXPERIMENTS

Syntonic and Multiple Wireless Telegraphy.

In the Digest of last week a concise account was given of the Slaby system of tuned and multiple wireless telegraphy, which system has recently been the subject of some successful experiments in Germany. As will be seen, the selective or syntonic feature consists first, in corresponding stations working with the same wave length, and in the employment at the receiving station of a vertical wire equal in length to a sub-multiple of the wave length agreed upon. By this means the receiving instrument will not respond to wave signals sent from the same or other stations where this condition is not complied with. Moreover, by a certain disposition of the aerial conductor it is made possible to receive simultaneously at a station messages of different wave length—this part of the system thus corresponding to multiplex wire telegraphy. Another part of the system consists in an "intensifier" arrangement corresponding to the local battery circuit of an ordinary telegraphic system, by means of which the potential of the received wave is increased, resulting in an increased effect on the coherer. The work of Prof. Slaby forms the most important contribution recently made to wireless telegraphy, and the system also appears to be a practical one. In tests made some weeks ago before the German Emperor, simultaneous messages were successfully received from two stations, one eight and the other two and one-half miles distant from the receiving point. The waves from the more distant station had to pass across the city of Berlin and were naturally attenuated by the high buildings and chimneys in its path, which effect, however, was counteracted by the application of the "intensifier" principle.

The work of Dr. Slaby above referred to received considerable prominence in cable newspaper dispatches, and—not unexpectedly—Mr. Nikola Tesla now comes forward with a claim of priority. In a letter to the New York *Sun*, Mr. Tesla says he has read with "deep astonishment" the statements made in his lecture before the Emperor by the Charlottenberg professor, who, moreover, had acknowledged that he—Tesla—is the "father of wireless telegraphy." Mr. Tesla also expresses disappointment that Dr. Slaby does not give him credit "for a beautiful invention which he [Dr. Slaby] calls the 'multiplier.'" "Have I not first described this device," he says, "and given rules for its construction and attunement? Was I not the first to apply it to wireless transmission?" For obvious reasons we have not been able to keep pace with all the numerous newspaper ascriptions to Mr. Tesla of revolutionary discoveries in electrical science, which probably explains our ignorance of the claim that he is the "father of wireless telegraphy," or indeed that the art of wireless telegraphy has in any manner benefited from his labors.

If Mr. Tesla would do what may fairly be asked of a man of his prominence—prepare a paper for the American Physical Society or the American Institute of Electrical Engineers covering the work he has accomplished in this branch—we shall be able to repair our own seeming neglect in not laying before our readers hitherto the record which would entitle him to be called "the father of wireless telegraphy."

Capacity of Electric Conductors.

In our issue of last week we quoted from a letter over the signature of Mr. Nikola Tesla in the New York *Sun* of Jan. 30, in which it is stated that the capacity of a fixed insulator conductor is not a fixed quantity, but varies with the hour of the day, with the season of the year, that it is influenced by moonlight, etc. It is also intimated that in consequence of this newly discovered fact a large part of technical literature will have to be rewritten. May we venture to express our doubts upon these propositions, with all due deference to Mr. Tesla. So far as text books are concerned, they are only stepping stones, and not keystones, in the structure of our

faith. The sooner they have to be cancelled, amended and rewritten, the healthier and more sturdy the growth of the science to which they relate, but the evolution of text books and of the knowledge they disclose must be like all other evolution, in a definite and orderly manner, in obedience to certain rules.

We have every reason to believe that the capacity of the condensers in our laboratories is within certain small limits a definite and constant quantity. The capacity of aerial wires insulated on poles and supported many feet from the ground seems to be a substantially constant quantity from day to day and year to year, provided that the surface of the earth is uniformly conducting. It has long been known—though not, it would seem, by Mr. Tesla—that when the surface of the earth is dry and ill-conducting, the apparent capacity of single wires supported above it is less than when the earth is wet and well-conducting. If, therefore, Mr. Tesla refers to variations of capacity between a fixed aerial conductor and the ground due to variation in the conductivity of the surface soil, he is virtually repeating a known proposition.

Concerning the variation in capacity of a conductor relatively to the earth with elevation above the earth, it is not a discovery that there must be a change of some sort in capacity. The experimental knowledge we possess concerning the capacity of very elevated conductors, is, however, so limited that there is room for valuable technical results to be observed in this direction, and if Mr. Tesla has made reliable observations of this character the science would owe him so much the more for their announcement. We hope that Mr. Tesla will publish any results which he may have obtained, in such form as may be available to electrotechnical workers.

It is quite clear that not only is no substantial technical information imparted to electrical engineers by articles of the nature which Mr. Tesla communicates so frequently to the daily press, but also that it is impossible for an electrical engineer to judge from such articles of the validity of the conclusions which are therein reached. It is quite possible that the apparent capacity of very elevated conductors might vary in a manner not generally appreciated or understood, and yet that the capacity of the ordinary conductors in the neighborhood of good conducting ground should be as fixed and constant a quantity as has always been supposed.

SLABY ON TESLA.—A special cable dispatch of Jan. 30 from Berlin says: "Prof. Slaby, of the Technische Hochschule, said in an interview to-day that he expected to revolutionize telegraphy if he was successful in applying his etheric system, which he calls spark telegraphy, to the present system of transmission by wire. He added that thousands of telegrams could then be transmitted simultaneously by the same wire. He characterized Nikola Tesla's expectations of an enormous reduction in the cost of electric currents as those of a fanatic, and said that the immediate future does not promise an improvement in the cost of conduction."

TESLA'S NEW TELEGRAPH.

AROUND THE WORLD WITH NO WIRE WITHIN EIGHT MONTHS OR SO.

Plants to Be Erected Will Be Not Experimental, but for Commercial Use, the Inventor Says Emphatically, and He Has the Necessary Financial Backing—The Instruments and the Mode of Operation.

Shortly after the New Year Nikola Tesla announced that having spent many of the later years of the nineteenth century in electrical experiments and investigations he purposed, giving to the world in the early years of the twentieth century some of the results in practical and commercial form of these experiments and investigations. Two weeks ago he brought out his "sanitary light," as he calls it. Yesterday he announced through THE SUN that the wireless telegraph --his system of the wireless telegraph—would be at the world's service in about eight months. By this system messages are to be transmitted to any distance on the earth's surface. Some of the machinery is now being constructed, and for the rest of it contracts will soon be awarded.

The chief essentials of Tesla's system are a transmitter and a receiver, with the earth, rather than wires, as the connecting medium. Both transmitter and receiver are rather simple machines or, at any rate, look so on his patents. The transmitter, which is set up at one point, receives the electrical energy from the source of power, intensifies it and sends it through a wire into the earth, through which it passes away in all directions. At a distant point from the transmitter, say in London, for instance, a receiver is set up. This is adjusted so that its vibrations are in unison with the vibrations of the transmitter. Being "in tune," as Tesla calls it, the receiver catches up from the earth the currents from the particular transmitter on the opposite side of the Atlantic, magnifying them many thousand times.

The cost of telegraphing by the wireless system will, Tesla says, be much less than by the cable system and messages may be sent much more quickly. Through the use of certain artifices it will be made impossible for a receiver in Calcutta, for instance, to take up the currents carrying a message from New York to London; and in time of war, one belligerent will not be able to interfere with, or take advantage of, the messages of the other belligerent.

Just where the first wireless telegraph office will be opened in New York Tesla does not care to tell at present. As for the financial end of the enterprise that has been privately arranged, and the inventor was most enthusiastic yesterday in his veiled references to the financial assistance he has received. In telling of the satisfactory outcome of his work on his wireless telegraph system and of his future plans in regard to putting it to commercial use, Mr. Tesla made the following statement to a SUN man:

"I am quite surprised at the lively interest manifested in my announcement to THE SUN that I am about to begin the construction of my plants for telegraphy without wires across the Atlantic. I have been steadily at work on the problem for seven years, and from time to time the advances I have made in the perfection of my apparatus have been noted. Three years ago I had so far progressed as to undertake the transmission with confidence, and had I been myself a wealthy man, I would have certainly attempted it. But I had to depend on financial help from others, and before I could conscientiously approach any one, I had to settle all doubt in my own mind as to the outcome of the experiment. This was one of the reasons for my going to Colorado, where, after eight months of investigation and perfection of my transmitters and receivers, I satisfied myself that, with my system, I could not only transmit messages across the Atlantic, but also across the Pacific Ocean.

"Three distinct experimental evidences of the practicability of my plan were obtained, each of which would have been sufficient to inspire me with confidence of success. One of these evidences was my discovery of the stationary electrical waves in the earth, which I have already published, and which demonstrates in a positive manner that vibratory currents can be transmitted through the terrestrial globe just as through a wire to the greatest distances. Another evidence I obtained by ascertaining the law of variation of the intensity of the effects produced by my transmitter at a distance, which enables me to design the transmitting apparatus for the required performance, just as I can construct a dynamo or steam engine for a given output. The third evidence I obtained by actual measurements of the intensity of the effects through varying distances of from 650 to 700 miles, and this was what may be considered the proof of the pudding.

"The greatest difficulties were encountered in the development of the transmitting apparatus, for not only was it necessary to produce impulses of enormous intensities, but they had to have certain characteristics to make them best suitable for the purpose. Another great trouble was to perfect methods for securing complete privacy and non-interference of messages, for only after this was assured could I hope to make a wireless transmission to great distance a practical success. It is quite easy to tune a circuit, but ordinary artifices were not adequate to giving that degree of safety against extraneous disturbance which was necessary, and a number of new expedients had to be resorted to. These have now been so far perfected that the same privacy is practicable as in transmission over a private wire.

"Another feature of great importance in the commercial exploitation of the system was the simultaneous transmission of a number of messages by the same apparatus, and in this direction I was fortunate enough to find a happy solution, enabling results to be attained which had been heretofore impossible."

"What is meant by tuning of circuits?" Mr Tesla was asked.

"Expressed in popular terms, tuning is the process of adjusting the vibrations of one circuit to those of another. The vibration is chiefly dependent on two quantities, which are designated as capacity and inductance, and in the coarse adjustment either one of these or both may be varied to give to the vibration the pitch required. But finer touches are necessary to insure the best success, and one might say that there is just as much difference between ordinary tuning, according to book instructions, and artistic tuning, as there is between a bar room picture and a painting by Sargent."

"What must a company operating with your system have, in order to transmit messages, for instance, from New York to London?" asked THE SUN man.

"The stations at either side will have to have transmitting and receiving apparatus, which, in substance, will be as I have described in my patents on energy transmission without wires. The essential part of the transmitter is a circuit, which is connected to the ground at one of its ends and to a conducting surface at the other end, and which is carefully adjusted so as to respond freely to the vibrations of the primary source of currents. Under these conditions currents of enormous intensities are produced in the circuit, which pass away through the ground in all directions. The circuit acts just like a pump in an ocean, drawing out and pumping in water rhythmically, creating ripples, which spread in ever widening circles, over the surface of the sea. Suppose the transmitter in New York is controlled by the key of the operator. Each time he depresses the key these ripples spread over the globe and reach London, where a receiving circuit arranged and connected similarly may be located. This receiving circuit is tuned with the greatest care to the vibrations of the transmitter, and just as a heavy pendulum is set swaying by weak impulses properly timed, so the receiving circuit is excited, the received impulses being thus magnified many thousand times. By this process impulses which would be in themselves inadequate to affect the receiving instrument, are rendered perceptible."

"You say that the currents from the transmitter pass through the earth in all directions. If that be true, then at any point on the earth's surface where a receiver is set up, those currents may be caught and messages received. Is that correct?"

"That, generally speaking, is true, but no message can be caught or read except by those receivers which are designed for the purpose. As I have stated before, I have perfected this part of my system to such a degree, that to read a message at some other place than that for which it is intended will be well nigh impossible. Obviously, any number of receiving stations may be provided, which will respond to definite signals or notes of the transmitter, as, for instance, in the transmission of time to the astronomical observatories, in weather reports, or the like, for which purposes I have devised a special apparatus.

"In time of war, could the telegrams sent by one belligerent to a distant point be caught up by receivers stationed in the possessions of the other belligerent, or in any way interfered or tampered with?"

"In such case still more rigorous measures would be adopted to exclude the possibility of the messages being read by others, and I have evolved some plans which would make the privacy absolute. The best the enemy could do would be to set up a powerful transmitter at the most effective place and try to muddle up the messages, but in such case, again, his manœuvre would be without avail, if certain provisions be adopted."

"How about the length of time consumed in transmitting messages by your system as compared with that through the cables?"

"The transmission will be much quicker than through the cables, because the latter are handicapped by what is known as electrostatic capacity. A number of schemes have been proposed to overcome this drawback, but all that I have so far examined are entirely inoperative."

"In the actual transmission of messages may the same apparatus in the way of keys and receivers be used as is employed in telegraphing over cables, and may the Morse code be used?"

"In the beginning I propose to resort to the instruments now used, but I have some plans in this regard which I hope will enable me greatly to increase the speed. The Morse code may, of course, be used."

"Are these plants to be simply experimental or are they to be commercially used? If for commercial use, when do you expect them to be in operation?"

"Most emphatically they are intended for commercial use. I have finished my experiments. I estimate that the work will consume about eight months, but I am prepared to encounter some delays and drawbacks, which always turn up somehow. You know, of course, that this is an engineering undertaking which requires special machinery and a variety of appliances, most of which are novel."

"Where are your first plants to be located?"

"I have determined the site on this side; the other is still under consideration. I prefer not to dwell on these details at present."

"What will be the cost of transmitting messages by your wireless system as compared with the cost of sending messages by the present cables?"

"Of course, it will be much cheaper; first, because of the relatively small cost of the apparatus, and secondly because of the greater speed of tranamission. The greater the distance the greater will be the advantage of the wireless transmission over the cables."

Mr. Tesla was asked whether the new system was to be exploited commercially by a company, by himself alone or by himself and a few friends. He said in reply that this will be wholly left to the judgment of those who furnish the capital. He did not believe in the inventor being his own business manager.

The New York Tribune February 15, 1901

MR. TESLA'S WIRELESS TELEGRAPHY.

HE HOPES TO SEND MESSAGES THROUGH THE EARTH ERE LONG.

Marconi, in England, Slaby, in Berlin, and other foreign electrical experts are attracting a good deal of attention just now by their achievements in wireless telegraphy. But Mr. Tesla is quite willing to have the public remember that he has been studying this subject for several years and as long ago as 1893 outlined a plan from which he hopes to secure great results before the new century is a year old.

There are two apparent points of difference between the Marconi and Tesla systems. The young Italian relies upon the ether to convey his messages, while Mr. Tesla employs the earth as a conduotor. To be sure, Marconi discovered that his apparatus worked better after he connected both transmitter and receiver with the ground, and it is not altogether clear that his first theory concerning the medium which conveys his messages is correct. Then, secondly, the particular form of energy employed by Marconi and Slaby is believed by them to be the so-called Hertz waves, which are not electricity, though produced by electrical apparatus. Mr. Tesla, on the other hand, utilizes true electric waves, of great power and frequency, such as can be generated by his much talked about "oscillator."

The advances which Mr. Tesla says he has made within the last year or two consist of the improvement of the power of his generating devices, and in the perfecting of his receivers, which are so designed as to respond only to messages intended for them. While the latter phrase would seem to describe other men's instruments as well, Mr. Tesla insists that he has developed the "tuning" system far beyond the possibilities reached by any one else, and he hopes to carry it still further. He doubts, for instance, whether Marconi could permit more than six or eight receivers in the range of a transmitter without more than a single instrument picking up a message. But Mr. Tesla believes that out of several hundred of his receivers only the right one will respond to a transmitter.

While on Pike's Peak Mr. Tesla made tests which satisfy him that he can, when the proper plant has been erected, establish communication between this country and Europe with the utmost ease. This conclusion rests largely upon electrical measurements and mathematical computation. There was no actual transmission of a message to a person on the other side of the globe, and hence no reply. But Mr. Tesla hopes to have his apparatus ready within the next eight months to furnish the latter kind of demonstration, and thus revolutionize transatlantic telegraphy.

The New York Herald February 16, 1901

PUTS NO LIMIT ON WIRELESS SYSTEM

Mr. Tesla Asserts His Ability to Send Messages for Thousands of Miles.

DEPENDS UPON VOLTAGE

Inventor Proposes to Connect Balloons at High Altitudes with Stations on the Ground.

CAN TRANSMIT POWER ALSO

HERALD BUREAU,
CORNER FIFTEENTH AND G STREETS, N. W.,
WASHINGTON, D. C., Friday.

Nikola Tesla, who has announced that he will be able to work his system of wireless telegraphy on a commercial scale in about eight months, was granted a patent early last May for his "system of transmitting electrical energy" through the higher strata of air without the use of wires.

Mr. Tesla's application sets forth at length the principles of his invention. In securing electricity for his wireless system he uses the electric "oscillator" previously patented by him. He asserts that the electric power produced in this manner has characteristics all its own. When radiated through the air at a pressure of millions of volts it transforms the atmosphere into a conductor of electricity, and if the voltage be high enough the electricity will be carried through the air for thousands of miles.

SENDING THROUGH HIGH STRATA.

A peculiarity of this phenomenon, Mr. Tesla says, is that by increasing the electrical pressure only slightly the distance that the electrical power will travel through the air is increased very greatly. He asserts that by increasing the electric power only fifty per cent the distance the electricity was carried through the air was increased sixfold. The electric energy is conducted most readily through the highly rarefied strata existing, say, at an altitude of five or six miles above the earth.

Mr. Tesla purposes, therefore, to send up a stationary balloon at the point from which he will send his power, and another at the point where it will be received. From each balloon he would hang a "terminal," consisting of a large disk. These disks would be connected by wire with stations on the ground.

In the transmission of power by this system Mr. Tesla would generate his electricity at a high pressure in his "oscillator," and would then pass it through a transforming apparatus, consisting of a primary and a secondary coil. From there the power, at a pressure of millions of volts, would be carried by a wire to the terminal suspended from the balloon. The electricity, radiating from it, would be conducted through the atmosphere to the second terminal, suspended from a balloon. The distance between these two could be indefinite, says Mr. Tesla. If the voltage be high enough, it would be possible to conduct the power through the air for thousands of miles.

FOR POWER PURPOSES ALSO.

From the receiving terminal, the power, which would be collected through the medium of the suspended disk, would be brought down to the receiving station by means of a wire. There it would be transformed by means of double coils. Telegraphic messages would then be rendered intelligible by ordinary methods.

In his claim Mr. Tesla says that not only messages can be sent in this manner, but that it is possible to transmit electricity for power purposes as well.

The New York Sun February 16, 1901

A TESLA WIRELESS DEVICE.

THE SYSTEM OF TELEGRAPHY PATENTED BY HIM ON MAY 1, 1900.

He Describes It as a System for Transmitting Electrical Energy Through the Higher Strata of the Air—Balloons to Be Used at the Sending and Receiving Stations.

WASHINGTON, Feb. 15.—The files of the Patent Office show that a patent was granted Nikola Tesla on May 1, 1900, for his system of transmitting electrical energy through the higher strata of air without the use of wires. His application sets forth at length the principles of his invention. In securing electricity for his wireless system he uses the electric oscillator, patented previously by him. He asserts that the electric power produced in this manner has characteristics all its own. When radiated through the air at a pressure of millions of volts, it transforms the atmosphere into a conductor of electricity, and if the voltage be high enough the electricity will be carried through the air for thousands of miles. A peculiarity of this phenomenon, he says, is that by increasing the electrical pressure only slightly the distance that the electrical power will travel through the air is increased very greatly. He asserts that by increasing his electric power only 50 per cent. the distance that the electricity is carried through the air is increased six fold. His electric energy is conducted much more readily through the more highly rarefied strata, existing say at an altitude of five or six miles above the earth.

He proposes, therefore, to send up a stationary balloon at the point from which he will send his power and another at the point where it will be received. From each balloon he will hang a "terminal," consisting of a large disc. These discs would each be connected by wires with the stations on the ground.

In the transmission of power by this system he would generate his electricity at a high pressure in his "oscillator" and would then pass it through a transforming apparatus, consisting of a primary and a secondary coil. From there the power, at a pressure of millions of volts, would be carried by a wire to the terminal suspended far up in the sky from the balloon. The electricity radiating from it would be conducted through the atmosphere to the second terminal suspended from a balloon. The distance between these two could be indefinite, says Tesla. If the voltage be high enough it would be possible to conduct the power through the air for thousands of miles. From the receiving terminal, the power which would be collected through the medium of the suspended disc would be brought down to the receiving station by means of a wire. There it would be transformed by means of double coils. Telegraphic messages would then be rendered intelligible by ordinary methods. In his claim Tesla says that not only messages can be sent in this manner, but that it is possible to transmit electricity for power purposes as well.

The New York Sun February 17, 1901

ARE THEY TESLA'S AGENTS?

Boston Has a New Theory to Account for the Men Camping Out in a Tent There.

BOSTON, Feb. 16.—It is now believed that the two men who have lived in a tent on Huntington avenue the last two weeks, and whose mysterious actions have caused much comment, are agents of Tesla. When a tall pole, sixty feet high, was put up a week ago and a number of wires were attached to a glass bottle, which was fastened to the top, it was believed that the men would endeavor to coax electricity from the clouds to heat the tent. To-day more wires were fastened to the pole and the men were working on something on the inside, which appears to be a huge battery.

This gives rise to the theory that it will be one of Tesla's relaying stations for his wireless telegraphy. One of the men who occupies the tent was asked to-night if he was an agent of Tesla, but he refused to commit himself, saying, "I may be and I may not be."

The New York Journal And Advertiser February 22 1901

TESLA READY TO TRY TRANSATLANTIC TALK.

His Assistant Starts from London for Portugal, and Tells How He Will Set Up Apparatus for Wireless Messages to America.

(Special Cable to the New York Journal and Advertiser.)

London, Feb. 21.—James Galbraith, a New York electrician from Tesla's Works, left London to-night for Lisbon with electrical apparatus for use in connection with a test of transatlantic wireless telegraphy. Galbraith said to the Journal correspondent:

"I am establishing a receiving station on or about the fortieth parallel. Tesla, at a point exactly opposite on the New England Coast, will try to set up communication.

"Tesla has not yet seen fit to disclose his system or the details of the transmitting and receiving apparatus, but the system is simple, like all great discoveries.

"Briefly, Tesla is satisfied that the ether is the conductor of all force in space, but is not a conductor unless set in agitation in the direction to be travelled. He discovered that the ether can be set vibrating in a straight line in any distance in an area unrestricted to length but circumscribed in circumference. Suppose a shell to be fired from Philadelphia to Lisbon, the path of the shell, if filled with vibrating ether, would represent Tesla's conductor.

"He proposes to establish with one set of apparatus a slender bridge of ether all aquiver with vibrations across the Atlantic. Here is the conductor. Over it he will transmit as over a cable or wire electrical currents, whose vibrations being infinitely slower than those of ether will pass over it as over a road. That is the essence of Tesla's theory.

"I am permitted to say nothing of the marvellous apparatus which will perform this scientific miracle. If, at my station, I find myself communicating with Tesla over the ether conductor, then, at that moment, space will be no longer untraversable; the very heavens may be opened up, for it is thus he purposes to bridge the gulf to Mars."

Tesla and Wireless Telegraphy.

THROUGH the New York *Sun,* Tesla announced last week that he is about to begin the construction of a plant for telegraphing without wires across the Atlantic Ocean, and that he estimated the work of preparation will consume eight months, adding, however, "but I am prepared to encounter some delays and drawbacks which always turn up somehow." From a statement in the same journal, it appears that the system to be employed was the subject of a patent issued to Tesla in May of last year. In looking over our files we find that two patents on "apparatus for transmission of energy" were issued to Tesla last spring, one dated March 20, and the other May 15; the latter is the one referred to by the *Sun.* We reproduce the following analyses of the patents from our issues of March 31 and May 26, 1900, respectively:

The patent dated March 20 (application filed Sept. 2, 1897), relates to the production at one point of an electrical pressure of such character and magnitude as to cause thereby a current to traverse elevated strata of the air between the point of generation and a distant point at which the energy is to be received and utilized. As illustrated, the apparatus consists of a generator supplying current to the primary of a transformer; the secondary consists of a coil of many turns and is connected at one side to the earth and at the other side to a terminal of large surface, maintained at a high elevation by such means as a balloon. The receiver duplicates this apparatus, except that instead of a generator being in one circuit of the transformer, receiving devices such as lamps and motors take its place.

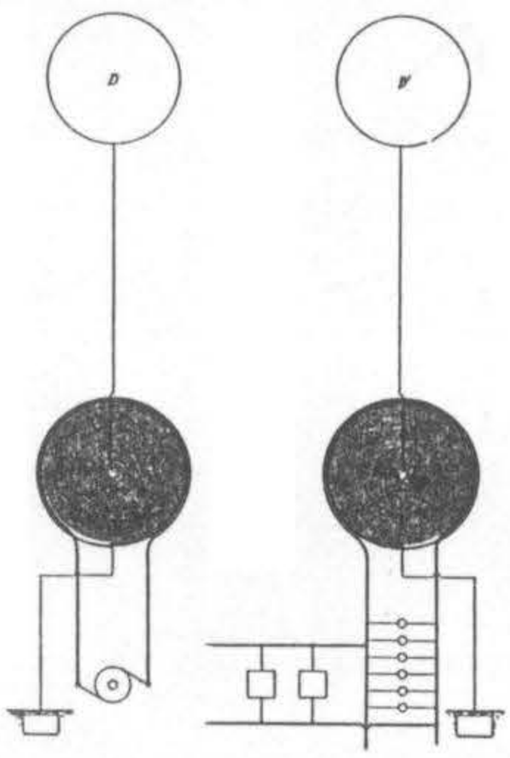


DIAGRAM OF TESLA APPARATUS.

The transformer consists of a coil of very large diameter wound in spiral form, either with or without a magnetic core. The inventor claims that this furnishes a practical method or system of transmission of energy through natural media without the use of wires.

The patent of May 15 (application filed Feb. 19, 1900), is on "apparatus for transmission of electrical energy." Referring to the accompanying illustration, which is a duplicate of that appearing in the patent of March 20, *DD'* are terminals of large surface maintained by such means as a balloon at a high elevation, the elevation depending upon the amount and quality of the work to be performed, the condition of the atmosphere, and also by the character of the surrounding country. The aerial conductors to these terminals are connected to the secondary of a spiral coil, the other end of the coil being connected to earth.

It is stated that the length of the thin wire in each of these coils should be approximately one-quarter of the wave length of the electric disturbance in the circuit, this estimate being based on the velocity of the propagation of the disturbance through the coil itself and the circuit with which it is to be used. For example, if the rate at which the current traverses the circuit including the coil be 185,000 miles per second, then the frequency of 925 miles per second would maintain 925 "stationary moves" in a circuit of 185 miles long, and each wave would be 200 miles in length. For such a low frequency, a secondary 50 miles in length would be used.

As will be noted from the illustration, the primary of the transmitting coil is supplied with a current by a dynamo, and the large coil of the receiver is connected with a circuit including lamps and motors. It is stated that the phenomenon involved in the apparatus is one of true conduction, and not to be confounded with the phenomena of electrical radiation which have heretofore been observed, and which from the very nature and mode of propagation will render practically impossible the transmission of any appreciable amount of energy to such distances as are of practical importance. The specification states that if the potential is sufficiently high and the terminals of the coil be maintained at the proper elevation where the atmosphere is rarefied, the stratum of air will serve as a conducting medium for the current produced, and the latter will be transmitted through the air "with, it may be, even less resistance than through an ordinary conductor."

SCIENCE BREVITIES.

"UNLESS, we are entirely wrong in our premises," says *The Electrical World and Engineer*, "we think Mr. Tesla is mistaken in his ideas of the mechanism of transmitting electric radiant energy from one planet to another. We hope that Mr. Tesla will publish a precise description of the phenomena which he observed, and which led him to suppose that ultra-terrean causes were at work. From his well-known experimental skill, a description of his observations before some scientific body would doubtless be extremely interesting. Our readers can not but agree to some extent with the editorial article in the New York *Tribune*, which, speaking for the lay public, ventures to say: 'It is to be regretted that the first news of the incident was not given to a scientific society of standing, rather than to a philanthropic organization or an ordinary newspaper.'"

TESLA'S WIRELESS TELEGRAPHY.

Long distance wireless telegraphy, if we may believe the current story of its latest developments, is about to take an enormous stride both in its reach and its rapidity, for we are shortly to be in possession of a means of wireless telegraphic communication across the Atlantic, by which we can send messages at considerably greater speed than is possible by the present cable. The feat is to be accomplished by the assistance of that "oscillator" with which the name of Nicola Tesla is so well identified. We are, all of us, fairly well familiar with the Marconi system in which Hertzian waves are utilized, the transmission of currents being aerial, or to speak more correctly ethereal. Mr. Tesla, however, manipulates his recently discovered "stationary electrical waves in the earth" by setting up "vibratory currents which can be transmitted through the terrestrial globe, just as through a wire, to the greatest distances."

According to public reports, Mr. Tesla during the past year or so has been devoting his time chiefly to the improvement of his generator and receiver. He claims to have so far perfected the system that by means of proper "tuning" he can direct his messages infallibly to any particular receiver. It seems that the primary purpose of his recent Pike's Peak experiments was a series of elaborate tests, the result of which satisfied Mr. Tesla that when a suitable plant is built, he can establish wireless electrical communication between the old and the new world. The system, as described in interviews with the author, involves the production of electrical vibrations of enormous frequency, a transmitter which receives the current, intensifies it, and sends it to the earth, through which it flows in every direction. A receiver which is adjusted so that its vibrations are in tune with those of the transmitter is set up, say in London, Paris or Berlin, picks up the vibrations, and intensifies them so that they become decipherable at the receiving station. These electrical vibrations are recoverable at any spot on the surface of the globe, provided that the Tesla receiver be at hand to pick them up, and intensify them to a point at which they may be read.

Talking With the Planets*

By Nikola Tesla

The idea of communicating with the inhabitants of other worlds is an old one. But for ages it has been regarded merely as a poet's dream, forever unrealizable. And yet, with the invention and perfection of the telescope and the ever-widening knowledge of the heavens, its hold upon our imaginations has been increased, and the scientific achievements during the latter part of the nineteenth century, together with the development of the tendency toward the nature ideal of Goethe, have intensified it to such a degree that it seems as if it were destined to become the dominating idea of the century that has just begun. But in this age of reason it is not astonishing to find persons who scoff at the very thought of effecting communication with a planet. First of all, the argument is made that there is only a small probability of other planets being inhabited at all. This argument has never appealed to me. In the solar system, there seem to be only two planets—Venus and Mars—capable of sustaining life such as ours; but this does not mean that there might not be on all of them some other forms of life. Chemical processes may be maintained without the aid of oxygen, and it is still a question whether chemical processes are absolutely necessary for the sustenance of organized beings. My idea is that the development of life must lead to forms of existence that will be possible without nourishment and which will not be shackled by consequent limitations. Why should a living being not be able to obtain all the energy it needs for the performance of its life-functions from the environment, instead of through consumption of food, and transforming, by a complicated process, the energy of chemical combinations into life-sustaining energy?

Some ten years ago, I recognized the fact that to convey electric currents to a distance it was not at all necessary to employ a return wire, but that any amount of energy might be transmitted by using a single wire. I illustrated this principle by numerous experiments, which, at that time, excited considerable attention among scientific men.

This being practically demonstrated, my next step was to use the earth itself as the medium for conducting the currents, thus dispensing with wire and all other artificial conductors. So I was led to the development of a system of energy transmission and of telegraphy without the use of wires, which I described in 1893. The difficulties I encountered at first in the transmission of currents through the earth were very great. At that time I had at hand only ordinary apparatus, which I found to be ineffective, and I concentrated my attention immediately upon perfecting machines for this special purpose. This work consumed a number of years, but I finally vanquished all difficulties and succeeded in producing a machine which, to explain its operation in plain language, resembled a pump in its action, drawing electricity from the earth and driving it back into the same at an enormous rate, thus creating ripples or disturbances which, spreading through the earth as through a wire, could be detected at great distances by carefully attuned receiving circuits. In this manner I was able to transmit to a distance, not only feeble effects for purposes of signalling, but considerable amounts of energy, and later discoveries I made convinced me that I shall ultimately succeed in conveying power without wires, for industrial purposes, with high economy, and to any distance, however great.

To develop these inventions further, I went to Colorado in 1899, where I continued my investigations along these and other lines, one of which in particular I now consider of even greater importance than the transmission of power without wires. I constructed a laboratory in the neighborhood of Pike's Peak. The conditions in the pure air of the Colorado Mountains proved extremely favorable for my experiments, and the results were most gratifying to me. I found that I could not only accomplish more work, physically and mentally, than I could in New York, but that electrical effects and changes were more readily and distinctly perceived. A few years ago it was virtually impossible to produce electrical sparks twenty or thirty feet long; but I produced some more than one hundred feet in length, and this without difficulty. The rates of electrical movement involved in strong induction apparatus had measured but a few hundred horsepower, and I produced electrical movements of rates of one hundred and ten thousand horsepower. Prior to this, only insignificant electrical pressures were obtained, while I had reached fifty million volts. But the time is not far away now when the practical results of my labors will be placed before the world and their influence felt everywhere. One of the immediate consequences

---

*Collier's Weekly.

will be the transmission of messages without wires, over sea or land, to an immense distance. I have already demonstrated, by crucial tests, the practicability of signalling by my system from one to any other point of the globe, no matter how remote, and I shall soon convert the disbelievers.

I have every reason for congratulating myself that throughout these experiments, many of which were exceedingly delicate and hazardous, neither myself nor any of my assistants received an injury. When working with these powerful electrical oscillations the most extraordinary phenomena take place at times. Owing to some interference of the oscillations, veritable balls of fire are apt to leap out to a great distance, and if any one were within or near their paths, he would be instantly destroyed. A machine such as I have used could easily kill, in an instant, three hundred thousand persons. I observed that the strain upon my assistants was telling, and some of them could not endure the extreme tension of the nerves. But these perils are now entirely overcome, and the operation of such apparatus, however powerful, involves no risk whatever.

As I was improving my machines for the production of intense electrical actions, I was also perfecting the means for observing feeble efforts. One of the most interesting results, and also one of great practical importance, was the development of certain contrivances for indicating at a distance of many hundred miles an approaching storm, its direction, speed and distance traveled. These appliances are likely to be valuable in future meteorological observations and surveying, and will lend themselves particularly to many naval uses.

It was in carrying on this work that for the first time I discovered those mysterious effects which have elicited such unusual interest. I had perfected the apparatus referred to so far that from my laboratory in the Colorado mountains I could feel the pulse of the globe, as it were, noting every electrical change that occurred within a radius of eleven hundred miles.

I can never forget the first sensations I experienced when it dawned upon me that I had observed something possibly of incalculable consequences to mankind. I felt as though I were present at the birth of a new knowledge or the revelation of a great truth. Even now, at times, I can vividly recall the incident, and see my apparatus as though it were actually before me. My first observations positively terrified me, as there was present in them something mysterious, not to say supernatural, and I was alone in my laboratory at night; but at that time the idea of these disturbances being intelligently controlled signals did not yet present itself to me. The changes I noted were taking place periodically, and with such a clear suggestion of number and order that they were not traceable to any cause then known to me. I was familiar, of course, with such electrical disturbances as are produced by the sun, Aurora Borealis and earth currents, and I was as sure as I could be of any fact that these variations were due to none of these causes. The nature of my experiments precluded the possibility of the changes being produced by atmospheric disturbances, as has been rashly asserted by some. It was some time afterward when the thought flashed upon my mind that the disturbances I had observed might be due to an intelligent control. Although I could not decipher their meaning, it was impossible for me to think of them as having been entirely accidental. The feeling is constantly growing on me that I had been the first to hear the greeting of one planet to another. A purpose was behind these electrical signals; and it was with this conviction that I announced to the Red Cross Society, when it asked me to indicate one of the great possible achievements of the next hundred years, that it would probably be the confirmation and interpretation of this planetary challenge to us.

Since my return to New York more urgent work has consumed all my attention; but I have never ceased to think of those experiences and of the observations made in Colorado. I am constantly endeavoring to improve and perfect my apparatus, and just as soon as practicable I shall again take up the thread of my investigations at the point where I have been forced to lay it down for a time.

At the present stage of progress, there would be no insurmountable obstacle in constructing a machine capable of conveying a message to Mars, nor would there be any great difficulty in recording signals transmitted to us by the inhabitants of that planet, if they be skilled electricians. Communication once established, even in the simplest way, as by a mere interchange of numbers, the progress toward more intelligible communication would be rapid. Absolute certitude as to the receipt and interchange of messages would be reached as soon as we could respond with the number "four," say, in reply to the signal "one, two, three." The Martians, or the inhabitants of whatever planet had signalled to us, would understand at once that we had caught their message across a gulf of space and had sent back a response. To convey a knowledge of form by such means is, while very difficult, not impossible, and I have already found a way of doing it.

163 MILES AN HOUR ON ELECTRIC ROAD

Germany Hopes To Be First in Field with Ideal Railway of Future.

FROM BERLIN TO ZOSSEN

Cars Now Building and Will Be Running Before the End of the Year.

KAISER WILHELM INTERESTED

Experts Here Say They See No Difficulties in the Way of Attaining Such a Speed.

That Germany is making big strides in the direction of the development of electrical railways is shown in a report which has just reached this country.

During the present year a railroad, with electricity as the motive power, will be in construction, the report says, from Berlin to Zossen, on the military line, and it is hoped that trains will develop a speed of 155 miles an hour.

This news was contained in a report sent to Washington by Richard Guenther, the United States Consul General in Frankfort. Under date of January 16 he wrote:—

> It is reported from Berlin, under date of January 14, 1901, that the railway of the future was the subject of discussion at an audience which Privy Councillor Rathenau, superintendent of the works of the General Electricity Company, has recently had with the Emperor. The Emperor expressed himself as being in favor of a complete change of the entire railway service.
>
> Mr. Rathenau gave the Emperor detailed information, emphasizing the necessity of constructing electrical railways for direct and rapid connection between Berlin and the principal cities of the German empire. For the purpose of furthering this project a number of prominent industrial and banking firms formed some time ago a society for investigation. The deliberations of this society will probably result in the opening for traffic during the current year of an electric railway the Secretary of War has placed at the disposal of the society—namely, the military line from Berlin to Zossen.
>
> It is hoped that a speed of from 125 to 155 miles per hour can be attained with cars of which one will be built by the General Electricity Company and one by the firm of Siemens & Halske. By raising the speed, which now averages thirty-seven miles per hour for fast trains, to 155 miles per hour, and by despatching the cars singly, the ideal railway of the future will have been reached.

EXPERTS ARE IMPRESSED.

Electricians in this country, and especially those who are concerned in the construction of railways, were much interested in this report yesterday. Nikola Tesla, who has not given much thought to the practical operation of railroads, said:—

> While I am not acquainted with the details of the project, I heartily commend the use of electricity for the propulsion of passenger trains. There are two ways in which it may be made available for this purpose without considering the storage battery. Either electricity is supplied to the cars, as by the third rail system, or it is generated on the train itself. The latter plan has been tried in France by Heilmann, and I consider it a rational departure.
>
> It can be readily shown that by adopting a proper steam engine and dynamo a train can be propelled with greater speed by the electricity generated than by the direct application of steam. The same considerations also apply to the ocean liners, and the adoption of mutiphase motors driven by steam turbines would materially increase the economy of propulsion of ocean liners and also the speed. The first departure of this kind will be a signal success, and I believe that at a time not distant the idea will be carried out.
>
> I conjecture, however, that the plan contemplated in Germany involves the supply of electricity in some way to the trains from central stations. In this manner, unquestionably, the greatest speed is attainable, as the amount of energy is not limited by the weight of the cars.

BEGINNING ALREADY MADE.

A. M. Young, of No. 100 Broadway, is an expert in electrical railway construction. He is a leading spirit in the Albany and Hudson Railroad and Power Company, which operates a third rail road extending from Hudson to Albany, a distance of thirty-five miles. On this line passenger and freight trains are run at an average speed of thirty-five or forty miles an hour, while a speed of sixty miles has been attained. Mr. Young said:

> It would not surprise me in the least to see a speed of 155 miles an hour attained on an electric railway. It all depends on the construction, of course. In this country I expect to see electric trains running at a speed of 100 miles an hour regularly, and that before long, too.

Charles W. Price, the editor of the Electrical Review, said:—

> I see no reason why 150 miles an hour should not be covered by an electric train. It is entirely feasible, and, indeed, speaking with experts some time ago on this very subject, they said 200 miles an hour would not be impossible.

Other men in positions to speak authoritatively spoke well of the project, and asserted that electricity was the motive power of the future.

Tesla and Wireless Telegraphy.—Announcement has been made in the daily papers, apparently by Mr. Tesla's request, or at any rate with his sanction, that he is prepared to telegraph across the Atlantic without wires. Assertions regarding remarkable discoveries by Mr. Tesla have been so numerous of late and so lacking in material confirmation that the scientific press has come to allow them to pass unnoticed, save by a word, here and there, of sarcastic comment. The daily papers treat the various pronunciamentos each after its kind, the yellow journals with weird pictures and big headlines, the more serious ones with skeptical paragraphs. Exactly what the inventor believes that he is prepared to do may be learned from the following, which *The Sun* (New York) publishes as a leading editorial (February 14):

"*The Sun* is authorized to state that the plans for the machinery of wireless telegraphy to signal across the ocean have been completed and a site for the plant selected by Nikola Tesla, and that the project will at once be actively begun. It is estimated that the time required to perfect the apparatus will be about eight months. We have received inquiries of late as to Mr. Tesla's place among inventors, and as to his credentials to fame. We don't know fully about those things, but we do know that it is Tesla who has given the world what is perhaps the most precious invention of the time, the electrical transmission of power, and we have seen the letter in which Professor Slaby, of Berlin, calls him the 'father of wireless telegraphy.' Will his gorgeous vision, described above, be realized? We don't know. So we must let doubt and incredulity gnaw upon the bare statement."

The attitude of the technical press is generally that of the electrical paper which recently remarked editorially that scientific men must be excused from giving opinions regarding announcements made through the medium of the daily press, and that when Mr. Tesla reads a paper on his alleged discoveries before some scientific body, it will be time enough to consider them seriously.

The daily newspaper reader of the last two months must have been impressed with the numerous and varied announcements of electrical experiments and developments of electrical phenomena credited to Nikola Tesla. It will be interesting to consider these announcements en bloc.

Mr. Tesla began the new year with his twentieth-century greeting to the National Red Cross society, in which he asserted that his delicate instruments at his mountain laboratory in Colorado had been unquestionably affected by electrical influences of planetary origin. Mr. Tesla believes that communication may possibly be carried on between the earth and Venus or Mars by using an enormous delivery of electrical energy, but lasting each time only a fraction of a second. He has been led to this conclusion, he says, by his ability to confine electrical currents of a pressure of 50,000,000 volts and to produce electrical movements up to 110,000 horsepower, and by other experimental results and investigations.

Together with the development of machinery for the production of powerful effects, Mr. Tesla has also perfected novel methods for detecting feeble electrical actions, which, he feels confident, will be important in a number of lines of scientific research.

Of special scientific interest is the announcement that the inventor has found electrical capacity, heretofore generally regarded as a constant, to be variable. He reached this conclusion after a series of experiments at different altitudes in Colorado, from which he was led to conclude that capacity varies with the height above sea level, with the relative height of the capacity with respect to the bodies surrounding it, with the distance of the earth from the sun, and with the relative change of the circuit with respect to the sun, caused by the diurnal rotation of the earth.

Next came the announcement by Mr. Tesla of great improvements in his system of tube lighting, which is said to give the nearest approach to daylight of any artificial illumination yet invented. The lamp is composed of a rectangular spiral of glass tubing containing rarefied gases which emit the radiations when submitted to an extremely high-frequency current.

While waiting for "a number of improvements that must be made before the new light can be generally introduced," scarcely a fortnight had passed before still another startling announcement was made. This time it was to the effect that "the plans for the machinery of wireless telegraphy to signal across the ocean have been completed and a site for a plant selected by Nikola Tesla, and that the project will at once be actively begun." Eight months is said to be the time required to perfect the apparatus, and pertinent to the announcement came a later report from London, stating that an agent of Mr. Tesla was en route to Lisbon to establish a receiving station on the Portuguese coast, which is to be placed in communication with a transmitter located on the New Jersey coast. Accounts differ as to the system to be used for this long-distance, wireless telegraphy. According to one, Mr. Tesla proposes to utilize electrical waves in the earth, by the use of which, with proper apparatus, he believes a wireless transmission of signals to any point on the globe is practicable. This system has been said by some to be the one that will be used in communicating under the ocean. Other accounts refer to a patent granted to Nikola Tesla about a year ago for a system of transmitting electrical energy through the higher strata of air without the use of wires.

An interesting factor that figures in all the Tesla experiments and investigations is the use of an "oscillator." This instrument, which has been evolved after considerable study and years of experiment is at the basis of all the recent developments of Mr. Tesla, and will, so the inventor asserts, accomplish many more wonders in the production of light, in telegraphy and telephony, and in the transmission of power.

Mr. Tesla has been criticized by more prosaic electrical men for raising expectations in the mind of the public which cannot be realized—for talking much and accomplishing little, in other words. His projects are certainly bold in conception and vast in extent. If any of the schemes originating in his fertile brain, and which have been "sprung" with such bewildering rapidity in the last few weeks, should actually, in practice, measure up to the claims made for it, it will be an achievement that will equal or surpass, perhaps, Mr. Tesla's work in the electrical power-transmission field a dozen years ago. In the meantime the electrical journals and all other observers must simply await developments with fair and unbiased minds.

MARVELLOUS RAY IS PRODUCED FROM A NEW ELEMENT.

Renders All Transparent Substances Luminous in the Dark—May Create a Greater Stir Than the X-Ray.

Will Prove a Sure Test for Diamonds and Promises to Be of Great Value to Wireless Telegraphy.

Washington, March 7.—A wonderful discovery has been made in Berlin which will create as much of a stir in the scientific world as did the Roentgen ray.

An element has been discovered by which all transparent substances, by the use of a certain ray, can be made to shine in the dark. By these rays it is possible to distinguish between genuine and artificial diamonds in the dark.

The discovery may also revolutionize the science of wireless telegraphy. The mysterious light by which these wonders can be performed is an element of the Becquerel rays, so called after the French chemist who discovered them.

News from Our Consul at Frankfort.

The news of this discovery came to the State Department from Richard Guenther, the United States Consul at Frankfort, and is published in the consular reports of this date.

Mr. Guenther, writing on January 31, says:

"A new technical journal, Kirchhoff's Technische Blaetter, to be issued within a few days, will contain an interesting article concerning the latest rays.

"In 1895 a French chemist discovered rays emanating from the element uranium which possessed properties similar to the Roentgen rays. They were called Becquerel rays, after their discoverer. But while the discovery of Roentgen aroused great interest in the whole civilized world and led to radical changes in medical diagnosis, the Becquerel rays were employed only in a minor way in physical laboratories, and an assertion by the French scientist Demarcays that they were not emitted from uranium, but from a new element, made no impression.

Important Experiments in Berlin.

"Recent experiments by the Berlin High School of Technology have proven this assertion—that a new element is responsible for the Becquerel rays—and the interesting fact has been observed that these rays render almost every transparent substance luminous in the darkness.

"These rays make it possible to tell genuine diamonds from artificial ones in the dark. This will prove of great practical importance in testing. The experiments have also resulted in obtaining, for the first time, larger quantities of the new element, which has demonstrated that rays emanating from a larger quantity make the air such a conductor of electricity that it is hoped this property can be utilized in wireless telegraphy.

"Experiments for this purpose are being made in the Berlin institution, but the deepest secrecy is maintained concerning them. It is stated that the results will soon be laid before the Emperor, which seems to indicate that the discovery is regarded as one of great importance."

Tesla's Views on the Discovery.

"All this is interesting, if true," was the opening remark of Professor Nikola Tesla, last night, as he proceeded to comment on the above dispatch.

"I am aware of the Becquerel results," he said, "and also of the discoveries of Currie with respect to the properties of uranium and polonium. These discoverers in presenting their results at that time conjectured that some other element might be responsible for the phenomenon observed.

"I do not believe that this discovery will be useful in wireless telegraphy. As a matter of fact, I think that telegraphy with rays in general is of little practical value. The Hertzian telegraphy will soon be abandoned, as experiments have shown it to be limited to short distances, and that, for other reasons, it is incapable of any valuable application for practical commercia use.

"In my papers on the Lennard and Roentgen rays, which were published in the Electrical Review two years ago, I advanced a theory which is now beginning to be appreciated by scientific men. I contended that all sources of radiant energy, including the sun and bodies at an appreciably high temperature, throw off minute particles of matter. I explained that this matter—as was evident from my experiments—was of some primal form, being split up in particles much smaller than ordinary atoms."

TESLA OR HOLDEN.

COLORADO SPRINGS people feel rather kindly toward Nicola Tesla because his greatest discovery or invention eventuated in this city.

If there are people in Mars, they certainly showed most excellent taste in choosing Colorado Springs as the particular point on the earth's surface with which to open communications. In fact, we may feel assured that if the mystical "One—two—three," which Tesla says may have been impulsed from Mars, could be translated from the planetary code, it would read "How is the weather in Colorado Springs?" or something equally localized.

Unfortunately other cities and other scientists do not feel this same consideration towards Mr. Tesla. Professor Holden, for instance, formerly director of the Lick observatory, in a current magazine, says:

"Mr. Nicola Tesla has announced that he is 'almost confident' that certain disturbances of his apparatus arise from electric signals received from some source beyond the earth. They do not come from the sun, he says; hence they must be of planetary origin, he thinks; probably from Mars, he guesses. It is a rule of sound philosophizing to examine all probable causes for an unexplained phenomenon before invoking improbable ones. Every experimenter will say that it is 'almost' certain that Mr. Tesla has made an error and that the disturbances in question come from currents in our air or in the earth. How can any one possibly know that unexplained currents do not come from the sun? The physics of the sun is all but unknown as yet. At any rate, why call the currents 'planetary' if one is not quite certain? Why fasten the disturbances of Mr. Tesla's instrument on Mars? Are there no comets that will serve the purpose? May not the instruments have been disturbed by the Great Bear—or the Milky Way—or the Zodiacal light?

"There is always a possibility that great discoveries, in Mars and elsewhere, are at hand. The triumphs of the science of the past century are striking proof. But there is always a strong probability that new phenomena are explicable by old laws. Until Mr. Tesla has shown his apparatus to other experimenters and convinced them as well as himself, it may safely be taken for granted that his signals do not come from Mars."

As a scientific guesser Professor Holden is not up to the Tesla Colorado Springs altitude. Mr. Holden believes in little or no water in Mars, a temperature far below the freezing point, little or no air, polar caps composed of frozen carbon dioxide, and "canals" that are in reality long cracks or crevasses in the planet's outer crust.

Frankly, we prefer the Tesla guess to that of Holden. It is a good rule in inventional science, "When you're going to tell one, tell a good one," and men have become great by observing the rule.

The man in the moon is gone and even H. G. Wells cannot bring him back, but we refuse to give up Mars. If the selection of Colorado Springs, as a point of superior knowledge where Martian signals would be most likely to be noticed and understood, is not a sign of superior intelligence, what more could be expected?

For the present, we stand by Tesla, and we have no doubt that ere long he will not only catch the repetition of his one-two-three message, but that he will be able to announce to the Martians the quotations and sales of the Colorado Springs mining stock exchange.

"FLIPPANT DISPARAGEMENT" OF MR. TESLA.

A NEW YORK daily—*The Sun*—complains that other papers utter "flippant remarks of disparagement" regarding Mr. Nikola Tesla's recent inventions. In commenting on this, *The Electrical World and Engineer* observes that the reason for this disparagement lies in the nature of things. It says that modern electrical inventors are generally diffuse in their efforts from the fact that opportunities to win new triumphs present themselves so abundantly in every direction that the most enduring energy and the highest genius are in danger of dissipation without net results. And this is the reason why the public once in a while gets impatient with the inventor and says rude things. *The Electric World and Engineer* continues:

"The tide of this flippant disparagement has been rising high of late, possibly because Mr. Tesla, with the onrushing enthusiasm of a man who sees things ahead to be done and is fertile in expedients for doing them, inclines to discuss them as tho they were already disposed of. With men of this stamp of intellect it will be so to the end, and it would be a prosaic world of mediocre achievement if it were otherwise. Just at present Mr. Tesla and his brilliant fellow countryman, Dr. Pupin, have their names associated in the public mind with new means of communicating across the ocean, and the newspapers, as the popular sources of scientific information, are full of the subject—a thing we heartily prefer to seeing the same columns filled with murder cases. But it is certain, in advance, that before they get through both Messrs. Pupin and Tesla will encounter a good deal more of 'flippant disparagement.' What is now being heralded as a novelty in each instance has been known to the electrical community for some time past, as we show in reproducing our articles of nearly a year ago; and probably before the goal is reached there will be several successive outbursts of sensational writing, followed by more of the 'flippant disparagement.'"

Obviously, the writer goes on to say, the tasks of telegraphing to Europe without wires or telephoning to Europe with a "loaded" cable are serious problems, but the impatient public does not realize that such things may linger unaccomplished many years to come, without any fault on the part of those who are striving to bring them to pass. He adds:

"In Mr. Tesla's case the injury done him by the jokes and jibes one finds in almost every paper picked up is the more severe because so much is promised in his name without his direct personal sanction. There seems no way to stop this abuse of confidence, from which Mr. Edison has also suffered to such an extent that a shotgun is his preferred reception for the average reporter. But just now Mr. Tesla holds the center of the sensational stage, and the talk about him is all the looser for the reason that it has so little that is tangible behind it as food. He has read no scientific papers before the societies for years, and, since his monumental series of patents on polyphase work, has taken out extremely few patents. We can recall only one or two in recent years. Hence the gossip that always besets a great genius has little to feed upon save the wild and absurd stories to which few of the authors hesitate even at signing Mr. Tesla's own name. In this way, as all such men discover, the lot of the genius trying to crack the nuts of modern civilization is not much better than that of his predecessors treated as lunatics or witches. And this 'flippant disparagement' falls hardest upon those who are not drawing-room inventors with drawing-board inventions."

The New York Herald March 22, 1901

MR. TESLA IS CONFIDENT.

Says His Wireless Telegraphy Invention Will Be Practically Tested Within Six Months.

PITTSBURG, Pa., Thursday.—Nikola Tesla is in Pittsburg placing a contract with the Westinghouse Electric Company for the manufacture of certain mechanical devices to be used in his experiments in wireless telegraphy across the Atlantic Ocean. Mr. Tesla says the success of his enterprise is more assured now than ever and that within the next six months his invention will be given a practical test. He hopes to establish the proof that it is not beyond the range of possibility to establish communication across the ocean without the aid of wires.

The New York Tribune March 22, 1901

WIRELESS TELEGRAPHY ACROSS OCEAN.

Pittsburg, March 21.—Nikola Tesla, the inventor, is in Pittsburg placing a contract with the Westinghouse Electric Company for the manufacture of certain mechanical devices to be used in his experiment on wireless telegraphy across the Atlantic Ocean. Mr. Tesla states that the success of his latest enterprise is more assured now than ever before, and within the next six months his invention will have a practical test. He hopes to prove that it is not beyond the range of possibility to establish communication across the ocean without the aid of wires.

WESTERN ELECTRICIAN

EVERY SATURDAY.

PUBLICATION OFFICES:

510 Marquette Building, - CHICAGO.

TELEPHONE, MAIN 1746.

Eastern Office, 148 Times Building, New York.

Trade Supplied by Western News Co.

COPYRIGHT.—Not only the title but the *entire contents* of each number of the WESTERN ELECTRICIAN are copyrighted. This paper is entered at the Chicago postoffice as mail matter of the second class.

SUBSCRIPTION, in advance, postage prepaid, $3.00 for a full year of 52 numbers; in clubs of four or more, $2.50, with free extra copy for eight subscriptions; foreign countries, $5.00 a year; single copies, 10 cents. When change of address is requested, the **old address** as well as the new should be given.

CORRESPONDENCE relating to electricity or any of its practical applications is cordially invited, and the co-operation of all electrical thinkers and workers earnestly desired. Clear, concise, well written articles are especially welcome; and communications, views, news items, local newspaper clippings, or any information likely to interest electricians, will be thankfully received and cheerfully acknowledged.

ADVERTISING.—THE WESTERN ELECTRICIAN—**the only general electrical paper published in the West**—thoroughly covers a territory *exclusively its own.* THIS IS A CLAIM WHICH CAN BE MADE BY NO OTHER ELECTRICAL JOURNAL IN THE UNITED STATES. Electrical merchants and manufacturers *desiring western trade* will appreciate the UNEQUALED VALUE of this journal as an advertising medium in its special field. Advertising rates are moderate, and will be furnished on application.

Astronomers do not seem to take kindly to Mr. Tesla's hypothesis that the inhabitants of Mars may be transmitting electrical signals to Earth. Edward S. Holden, formerly director of Lick Observatory, in a recent article in McClure's Magazine, is disposed to be sarcastic: "Mr. Nikola Tesla has announced that he is 'almost confident' that certain disturbances of his apparatus arise from electric signals received from some source beyond the earth. They do not come from the sun, he says; hence they must be of planetary origin, he thinks; probably from Mars, he guesses. It is a rule of sound philosophizing to examine all probable causes for an unexplained phenomenon before invoking improbable ones. Why fasten the disturbances of Mr. Tesla's instruments on Mars? Are there no comets that will serve the purpose? May not the instruments have been disturbed by the Great Bear—or the Milky Way—or the Zodiacal Light? Until Mr. Tesla has shown his apparatus to other experimenters and convinced them as well as himself, it may safely be taken for granted that his signals do not come from Mars." Mr. Holden is perhaps unnecessarily severe on Mr. Tesla; but, unfortunately, the electrical inventor has invited criticism of this sort by the vague, mystical way in which he chose to make public announcement of the disturbances on which his assumption is based.

ELECTRICAL MAGIC BY GREAT WIZARDS

"Miracles" Shown in Matter of Fact Way by American Institute of Electrical Engineers.

BARRELS OF TALK ON TAP FROM PIANO WIRE

Nikola Tesla and His Audience Cheer Thomas A. Edison, Who Gives Encouragement to His Successor in the Field of Invention, Who Makes the Deaf Hear.

Ray! Ray! Ray!
C—O—L—U—M—B—I—A.
Edison.

With such hearty welcome was "the Wizard of Menlo Park" received when he entered the lecture room of Havemeyer Hall, at Columbia University last night.

Nikola Tesla was giving experimental demonstrations with an electric oscillator when he saw Mr. Edison entering. His own greeting had been generous and hearty. When he saw the greatest of all American inventors Mr. Tesla stopped his work and grasped Mr. Edison's hand, which he shook as he led him to a seat. The great audience appreciated the courtesy of the younger man and responded with cheers for both.

The American Institute of Electrical Engineers held what it was pleased to call a "conversazione" at Columbia University last night. In reality it was an electrical exposition, and the most complete ever known in America. Fully two thousand guests had been invited, and few of those that received invitations failed to attend. The Engineering Building and Havemeyer Hall were given over to the electrical engineers and their guests, and every room in the two great buildings was used.

Matter of Fact "Miracles."

While there was nothing exhibited that was absolutely new, there were on exhibition inventions of which the public has only barely heard. "Miracles" were performed in a matter of fact way that left the beholders too dazed to do more than exclaim. Many of the wonders in operation are of too technical a nature to appeal powerfully to the layman in electric matters. Others are so practical that their value is easily understood.

Professor Waldemar Poulsen's telephonograph was exhibited in the Engineering Building, by Messrs. Lemvig Fog and Emil S. Hagemann, of Copenhagen, Denmark, and Mr. William A. Rosenbaum, of New York. This exhibition attracted the enthusiastic attention of all who saw it, and none was louder in praise than Mr. Edison, who gave great credit to the inventor for his work.

It was Jules Verne who told of conversation being frozen into the air to be heard when the weather moderated. While the Frenchman's dream has not yet been realized, Professor Poulsen has succeeded in packing into an electrically charged piano wire a conversation that may be drawn out much as one draws wine from a cask.

The apparatus, as exhibited last night, consists of a brass drum, eleven by five inches, upon which is wound piano wire. Resting upon the wire is a tiny electro magnet, which is connected to a carbon telephone transmitter, two cells of battery and preferably an induction coil.

Speech Put on Tap.

When the transmitter is spoken into, it acts as a tap on the battery, causing currents of varying strength, in proportion to the strength of the sound waves, to pass through the electro magnet. The current causes the magnet transversely to magnetize the steel wire as the drum resolves, and the magnetic lines of force are permanently recorded therein.

After the steel spiral is filled—which operation takes about 39 seconds, and permits the recording of 100 to 120 words—the tiny magnet is placed in its original position and connected with a Bell receiving telephone. The cylinder is again revolved, and as the magnetized steel wire passes before the poles of the electro-magnet it forms a species of magneto-electric generator, giving out currents of electricity of a strength and direction corresponding to the magnetization of the steel wire, which correspondingly affect a Bell telephone held to the ear, and reproduce the sounds and words originally spoken with absolute fidelity.

In addition, there was shown the band form of telephonograph and a dictation machine for office use. The band form gives the machine a practical value, as it makes it possible to extend the dictation almost indefinitely. The record is wiped out at the will of the operator, or retained permanently. There is no waste of material. The telephonograph is not yet considered perfect by its inventor, who is constantly at work upon it. The reproduction is similar to the sound of the telephone, the buzzing of the phonograph being obviated.

Aerodrome Pictured in Flight.

In the same room with the telephonograph was exhibited a remarkable collection of aeronautical pictures, comprising photographs shown for the first time, of Professor S. P. Langley's aerodrome in actual flight. Dr. Alexander Graham Bell took a photograph which shows the aerodrome in the air at least one hundred feet from the earth. At the time the picture was taken the machine made a successful flight of more than three thousand feet. The velocity attained was twenty-five miles an hour in a course that was constantly taking the aerodrome "up hill."

Peter Cooper Hewitt in another room of the Engineering Building exhibited high candle power lighted the room, using ordinary 115-or vapor. One large tube lamp of 1,000 candle power lighted the room, using ordiary 115-volt direct current. The room was perfectly lighted, remarkable color effects being produced at the will of the exhibitor. At times an effect so ghastly as to affect the nerves of many was produced. By the use of another apparatus Mr. Hewitt showed the relation of voltage to the length and the diameter of the tubes used.

Where the Deaf Heard.

On the third floor of the Engineering Building Mr. K. Hutchison exhibited the akouphone and the akoulallon, the microtelephonic instruments of his invention, by means of which he makes the deaf hear.

A class from the New York Institution for the Instruction of the Deaf and Dumb were present to illustrate the value of the akouphone. They were selected because of the fact that they are the most hopelessly deaf of all in the institution. Among them was Orris Benson, who has been deaf and blind since birth.

Benson has had five hours of training with the akouphone and is now somewhat accustomed to it. He listened to music from a phonograph, and when the sensation of sound first penetrated his brain he threw up his "talking hand" and told his teacher, who was with him, that the music sounded sweeter to him than it ever had before. Later he held a short conversation with Mr. Hutchison.

"Hello!" said the young inventor.

"Hello!" responded the boy whose life had so long been mute. His voice was hollow and metallic, but his enunciation was not bad.

"Can you say 'mamma' and 'papa'?"

"Mamma, papa," came back from Benson, who divided the words into syiables, as does a talking doll.

"Are you a bad boy?"

Benson shook his head. For a moment he studied, then replied:—

"Bad boy—no."

Other members of the class were eager to test the akouphone. When they heard music or words their faces changed in expression, losing that set condition of features that marks those whose ears are deaf.

For hours the room in which Mr. Hutchison exhibited his invention was crowded. Mr. Edison and Mr. Tesla were there, and complimented the young inventor for producing the instrument.

Telegraph Picture Machine.

Mr. H. R. Palmer exhibited a fac-simile picture telegraph in operation. This system is similar to that which has been successfully used in transmitting pictures and sketches over long distances, employing ordinary telegraph circuits.

Dr. Michael I. Pupin exhibited his original apparatus used in developing the recent invention by which he made it possible to telephone long distances under the ocean. Dr. Pupin's system consists in the location of inductance coils in the line at distances which are small fractions of a current wave length.

Wireless telegraphy, as worked out for the use of the United States government, was exhibited and explained in connection with a field telephone and telegraph kit used in the Philippine campaigns.

Professor Elihu Thomson exhibited a new rotary electrical apparatus consisting of an iron sphere heavily electroplated with copper and mounted so that it may revolve on any axis or in any plane. Surrounding this sphere are three coils in planes at right angles to each other. By suitably energizing these coils with polyphase current the sphere may be made to revolve on any axis or in any direction, or it may be said to illustrate a three dimension polyphase system.

These are only a few of the many things that were exhibited and explained. In the lecture room Mr. Tesla gave demonstrations at nine o'clock and at ten o'clock. Each time he had large audiences that marvelled at the wonders he performed, though few of them were new. With the room darkened Mr. Tesla walked about brandishing long glass tubes which flashed in a manner resembling phosphorescence that was not entirely canny.

In one hand he carried what seemed like an ordinary glass globe, fifteen inches in diameter. Suddenly a flash of electricity appeared many feet from the demonstrator, and the globe glowed as though it were filled with living fire. Again the room was darkened, and from what appeared to be an ordinary insulated wire sparks shot in every direction, filling the atmosphere for yards around with fire that drove away curious persons who had crowded too close to the demonstrator.

Mr. Tesla apologized for the failure of many of his experiments, as being due to flaws in his apparatus developed after it had been installed.

THE latest great application of natural force to a useful purpose, in which it is announced that Nikola Tesla is especially interested, is an electrical process for purifying water, says the Baltimore "Herald." The system contemplates, it must be understood, not the shaking of a few millions of unhealthy microbes out of a few gallons of water. Mr. Tesla deals in no such small schemes as that. The plan, when made to work, will be expected to purify the inflow of the open rivers that contribute to the supply of large cities. Instead of swallowing with every glassful of the murky beverage which flows from the faucet a large percentage of odorous protoplastic germs, the electrified water of Mr. Tesla may be expected to possess the sparkle and sweetness of the aqueous fluid that flows from the mountain rocks. He could confer no greater boon upon humanity. Let us hope this time for practical results.

WESTERN ELECTRICIAN

EVERY SATURDAY.

Vol. XXVIII. CHICAGO, APRIL 20, 1901. No. 16

The Institute Conversazione.

In the dictionary a conversazione is defined as an assembly for conversation, "particularly on literary or scientific subjects." But the gathering at Columbia University, New York, on the evening of April 12th was that and more, being also an exhibition of one evening's duration of the latest advances in the science and art of electricity. It was held by the American Institute of Electrical Engineers, with the co-operation of the university authorities, and was a brilliant success. The effort to present electrical features of real novelty was satisfactorily carried out, and the attendance was worthy of the exhibits and demonstrations, including such men as Edison, Tesla, Elihu Thomson, Sprague, Bell and Pupin. The affair was held in the Engineering building and Havemeyer Hall, the latter being devoted exclusively to Tesla's demonstrations. In all there were 32 special exhibits. A collation was served on the third floor of the Engineering building. The committee of arrangements consisted of W. S. Barstow, chairman, and Edward Caldwell, W. J. Hammer, R. T. E. Lozier, F. B. Crocker, T. C. Martin, C. W. Rice and George F. Sever. The reception committee embraced a long list of well-known names, with Carl Hering as chairman and R. W. Pope as secretary. Following are brief accounts of exhibits.

Pupin's Improvement in Long-distance Telephony.

Professor M. I. Pupin of Columbia University was in attendance and explained to visitors the original apparatus used in developing his recent invention for the improvement of long-distance land and ocean telephony, consisting in the location of inductance coils in the line at distances which are definite small fractions of a current-wave length. This apparatus was shown in the basement of the Engineering building.

Tesla's Experiments.

In Havemeyer Hall, Nikola Tesla performed startling and suggestive experiments with his oscillator—experiments remarkable to see, yet impossible adequately to describe. An interesting feature of the Tesla demonstration was the high tribute paid Tesla by Edison's presence at his demonstration, for Mr. Edison's reluctance to attend functions of all sorts is well known. The entrance of Edison was the signal for tremendous cheering on the part of those present, and Tesla's smiling and evident appreciation of the high compliment paid him by the older inventor was by no means the least interesting feature of the evening.

As is often the case where highly scientific demonstrations of an impromptu nature are essayed, and with a short time for preparation or test of apparatus after transportation, Mr. Tesla had to suffer his disappointments. In the midst of his most remarkable experiments, and at a point where he had hoped forcibly to illustrate certain remarkable phenomena relative to the transmission of energy without wires, well known to himself, but it is safe to say, new to the majority of those present, the transformer on the city electric-lighting system, that had been tapped or temporarily installed by the college authorities to furnish Mr. Tesla his main supply of current gave out. The manly and patient manner in which Mr. Tesla endured what must have been a most trying ordeal won him the sympathy of every practical scientific man present. The fact, too, that he had worked throughout the entire preceding night and had brought to Havemeyer Hall an astonishing amount of heavy yet delicate and intricate apparatus, earned him the thanks of everyone present for his effort, as he smilingly put it, "not to instruct, but to amuse." Fortunately for Mr. Tesla, however, he was enabled to make an exhibition of high-frequency induction effects and of high-tension discharges of a highly interesting character. Edison's entrance and later that of Tesla were greeted with cheers by the Columbia students. Tesla explained that he was going to use an electric oscillator to produce wave vibrations which were to be discharged in various parts of the room by means of a large transmitting cable. The brilliancy of the electric light from a large coil was made to decrease and diminish by Tesla rubbing his hands along the sides of the coil.

Geissler tubes were made fluorescent, and a beautiful effect was produced by waving vacuum tubes charged with the electric current.

The later experiments partook of the nature of the results obtained by induction currents. A glass moon was lighted from a huge wire coil, the current passing through the air as in wireless telegraphy. Tinfoil was heated from the center of the coil. When the coil was short-circuited, the foil heated so quickly that the demonstrator dropped it with smothered exclamations. By far the most spectacular performance was the last. A huge, flat coil, 10 feet high, was constructed in the front of the room and the current turned on in full force. Sparks leaped six feet in all directions from the end of the wire, and the heat was so intense that the insulation began to burn. The audience felt uncomfortable and Tesla smothered the flames, remarking that "It's just nothing."

FIG. 1. THE INSTITUTE CONVERSAZIONE.—PICTURE-TELEGRAPH MACHINE AT CHICAGO END OF CIRCUIT.

Palmer and Mills' Picture Telegraph.

H. R. Palmer's and Thomas Mills' "facsimile picture telegraph" was one of the exhibits. This instrument is worked on a system whereby half-tone pictures, sketches, handwriting and the like can be transmitted over long distances by employing ordinary electrical circuits.

An attempt was made to send and receive pictures to and from Chicago, the instrument on exhibition having been connected with long-distance telephone wires, but the experiment failed this time, although the efficacy of the appliance has previously been demonstrated over long distances. The explanation for the failure was that the induction in the underground cables in New York caused the trouble.

It is not claimed that this apparatus is entirely perfected for commercial use nor that it involves any new principle in picture transmission, the idea being to utilize synchronously revolving cylinders, the one at the transmitting end having the picture on a prepared zinc plate treated with an insulating compound to break the circuit of a metallic stylus in contact with it. At the receiving end is a duplicate machine, in which, however, a pen takes the place of the stylus and produces, on a sheet of paper on the receiving cylinder, the outlines or dots transmitted by the electrical impulses of the transmitting cylinder. Automatic synchronizing apparatus is provided. In the experiment arranged for the Institute Mr. Palmer was at the New York end and Mr. Mills in Chicago. The accompanying picture (Fig. 1) shows the instrument set up in a room at the Quadrangle Club of the University of Chicago and was taken on the evening of April 12th, at the time of the test. Mr. Mills, one of the inventors, is in the chair in the foreground, with an assistant at his left. The machines will be exhibited at the Pan-American Exposition by the International Electrograph company of Cleveland, of which Mr. Palmer is president.

Poulsen's Telephoncgraph.

Poulsen's telephonograph was exhibited by Lemvig Fog and Emil S. Hagemann of Copenhagen, Denmark, and Mr. William A. Rosenbaum of New York. This exhibition attracted the enthusiastic attention of all who saw it, and none was louder in praise than Mr. Edison, who gave great credit to the inventor for his work. The apparatus, as exhibited, consists of a brass drum, 11 by five inches, upon which is wound piano wire. Resting upon the wire is a tiny electromagnet, which is connected to a carbon telephone transmitter, two cells of battery and preferably an induction coil. When the transmitter is spoken into, it acts as a tap on the battery, causing currents of varying strength, in proportion to the strength of the sound waves, to pass through the electromagnet. The current causes the magnet transversely to magnetize the steel wire as the drum revolves, and the magnetic lines of force are permanently recorded therein. After the steel spiral is filled—which operation takes about 39 seconds, and permits the recording of 100 to 120 words—the tiny magnet is placed in its original position and connected with a Bell receiving telephone. The cylinder is again revolved, and as the magnetized steel wire passes before the poles of the electromagnet it forms a species of magneto-electric generator, giving out currents of electricity of a strength and direction corresponding to the magnetization of the steel wire, which correspondingly affect a Bell telephone held to the ear and reproduce the sounds and words originally spoken with absolute fidelity. In addition, there was shown the band form of telephonograph and a dictation machine for office use. The band form gives the machine a practical value, as it makes it possible to extend the dictation almost indefinitely. The record is wiped out at the will of the operator, or retained permanently. There is no waste of material. The telephonograph is not yet considered perfect by its inventor, who is constantly at work upon it. The reproduction is similar to the sound of the telephone, the buzzing of the phonograph being obviated.

Hewitt's Mercury-vapor Lamp.

One of the most remarkable exhibits, due largely to its importance as bearing upon the future of the incandescent electric light was that of Mr. Peter Cooper Hewitt. With a knowledge of the present efficiency of ordinary types of arc and incandescent lamps and also that of such lamps as the Nernst, Mr. Hewitt's record with his mercury-vapor lamp, operating at 74 volts with three amperes, consuming a total of 222 watts and giving 700 candlepower, or, in other words, giving light at the rate of 0.32 watt per candle, measured horizontally at right angles to the tube—such a result as this means something to the electric-lamp industry. Mr. Hewitt was naturally very solicitous that those present should use the ammeters and voltmeters for themselves, and many verified the tests. This mercury-vapor lamp operates on ordinary 115-volt, constant-potential circuits and gives a most peculiar light, which will doubtless subject it to some criticism. In this lamp, it was explained, a gas is used as the illuminating medium, instead of a filament or a carbon pencil,

as in other electric lamps. Mr. Hewitt's gas is mercury vapor. The lights are long and cylindrical in shape. At the bottom of each lamp is some mercury, from which, when the current of electricity has been run through it, there issues the vapor referred to. The current is transmitted to the mercury direct. The most peculiar colored light is emitted from the tubes. It is half purple, half green. This, according to the explanation of the exhibitor, is a disadvantage, but it can be obviated by the use of counteracting colored shades. The reason the crowd seemed to be especially interested in the long tubes was the fact that everybody who came into the room had his or her features so distorted that the skin of the face appeared to be covered all over with ghastly, violet-colored eruptions. The lips that came under the light seemed purplish gray, the pupils of the eye lost their natural hue, whatever it had been, and assumed a greenish tinge.

Ryan and Phelon's Radiographing of Alternating-current Waves.

Professor Harris J. Ryan of Cornell University and Professor J. O. Phelon exhibited a most valuable application of a Braun tube in radiographing of alternating-current waves. This is a method for securing stationary and continuous diagrams or cards of alternating-current values, which are conveniently recorded by means of a simple form of pantagraph, that is run over the luminous diagram and operates a lead-pencil.

Hutchison's Akouphone.

M. R. Hutchison exhibited two instruments known as the akouphone and akoulalion, and which are intended to make the deaf hear. W. H. Van Tassel of the New York Institute for the Deaf and Dumb brought eight of the deafest boys in the institution for experimental purposes. One lad was born deaf, dumb and blind. He was led to the apparatus and the earpieces fixed over his head.

The operator spoke into the akouphone, which is described as a microtelephonic instrument, so constructed as to reproduce and largely intensify sounds and still preserve their quality. The boy jumped when words were spoken, showing the novelty of all sound to him. When the word "hello" was repeated many times he made an effort to repeat the sound, with only partial success. A phonograph was attached to the receiver and band music was played. A faint smile appeared on the boy's face and he spelled out the word music with his fingers to his preceptor. He began to keep time with his hands and his face was soon wreathed with smiles. He resisted when the cap was removed from his head. Mr. Van Tassel said experiments with the akouphone on another inmate of the asylum had resulted in great success.

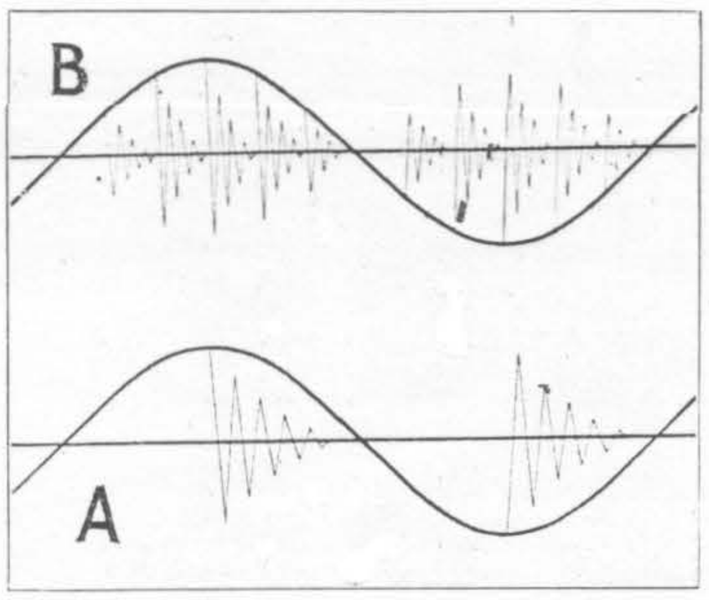

FIG. 3. THE INSTITUTE CONVERSAZIONE.—ANDREWS' SPARK EXPERIMENTS.

Elihu Thomson's Apparatus.

Professor Thomson showed a dynamo static machine, containing a small direct-current motor, the windings of which are tapped and connected to two rings, giving a primary alternating current for the operation of a step-up transformer, which gives a secondary current of about 20,000 volts, being capable, however, of regulation through a wide range. The tops of the alternating-current waves of high potential obtained from this secondary transformer are used to charge a number of glass-plate condensers in parallel. The rotating frame synchronously driven with the motor makes the connection to the condensers periodically and in synchronism with the alternating current. The connection by the rotating frame is alternately in parallel and in series, condenser plates being charged to 15,000 volts and with 10 in parallel, giving 150,000 volts when connected in series. The machine therefore furnishes from low-pressure direct current, high-potential discharges of definite polarity at the discharged terminals.

A new rotary electrical apparatus, consisting of an iron sphere heavily electroplated with copper and mounted so that it may revolve on any axis or in any plane, was also exhibited by Professor Thomson. Surrounding this sphere are three coils in planes, at right angles to each other. By suitably energizing these coils with polyphase current, the sphere may be made to revolve on any axis or in any direction, or it may be said to illustrate a three-dimension polyphase system. This apparatus illustrates the principles of the gyroscope and Bohnenberger sphere.

A third device was an illuminated disk mounted on a shaft free to rotate and having applied to it in special ways alternating-current magnetic fields, the rotations of the disk involving interesting paradoxes.

Andrews' Spark Experiments.

The following experiments were made by Mr. W. S. Andrews to determine some features of a high-frequency spark, the apparatus being energized from an alternating-current lighting circuit of 118 volts and 58 cycles. For convenience of observation.

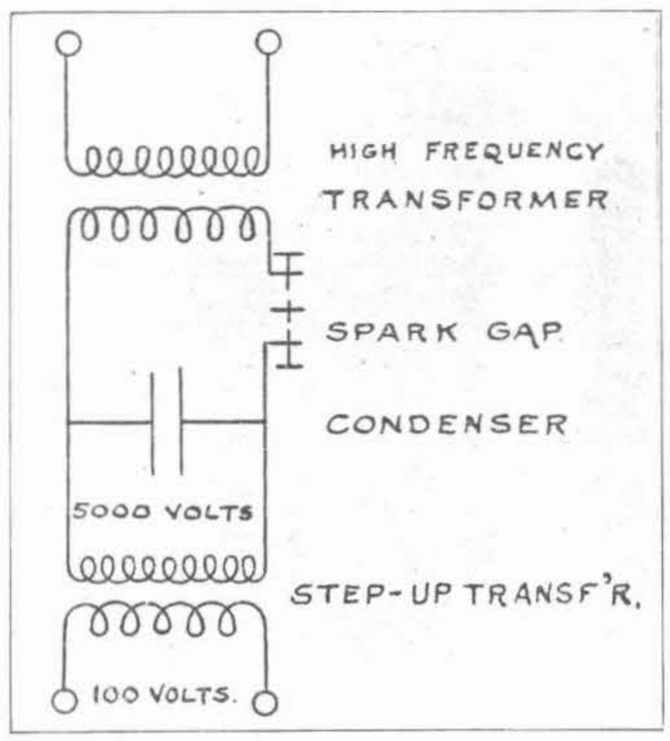

FIG. 2. THE INSTITUTE CONVERSAZIONE.—ANDREWS' SPARK EXPERIMENTS.

the spark was passed through a glass tube having a bore of about 0.25 millimeter. The current was conducted into the tube by wires inserted in the ends, leaving an air gap about five inches long inside the tube, the ends of which were not sealed. The tube was revolved while illumined by the discharge, the optical effect being a circle of bright radial lines. Under these conditions, the number of primary radii is obviously determined by the ratio between the alternations and the speed of rotation, but the characteristics of the primary radii may be changed by manipulation of the apparatus.

Referring to the theoretical diagram of high-frequency apparatus shown in Fig. 2, when the spark gap is set at a certain length and the potential of the transformers adjusted, so that the condenser discharge will only just arc across it, the radii will appear as single lines, indicating that the condenser discharges only once during a half wave. See (A), Fig. 3. If the primary potential is now increased, or if the spark gap is shortened, the single radii will be seen to open out like a fan into two or more lines, thus indicating a corresponding number of condenser discharges during each half wave. See (B), Fig. 3.

To obtain permanent records of the different effects, photographs were taken. Fig. 4 shows a snap exposure of the high-frequency sparks during two half waves. Fig. 5 shows a star produced when the tube was revolved at 430 revolutions per minute. During each half revolution eight compound radii were formed in each half of the circle, corresponding to eight half waves in a 58-cycle current.

"It would be difficult, if not impossible," says Mr. Andrews, "to record any purely high-frequency oscillations by the present method, as a sufficiently high speed of rotation could not be attained. The results described, however, appear to present a clear proof that each half wave may be the source

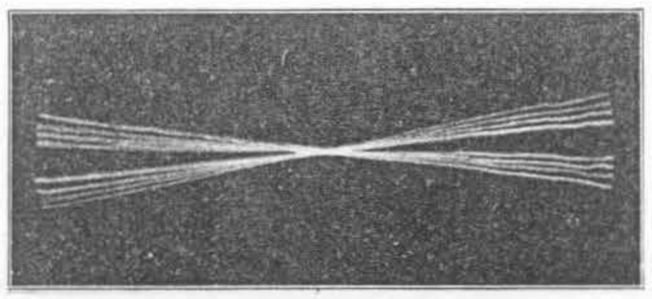

FIG. 4. THE INSTITUTE CONVERSAZIONE.—ANDREWS' SPARK EXPERIMENTS.

of a number of groups of high-frequency oscillations. It therefore follows that an arc across a high-potential circuit containing inductance and capacity ruptures itself instantly, so that, if the voltage is high enough, it can occur repeatedly during each half wave."

Nernst Lamps.

Mr. William J. Hammer exhibited European "Nernst" and other electric lamps. These lamps were shown in operation during the evening. Mr. Hammer also showed his personal collection of photographs from Hiram Maxim of his flying machine and also of his own trip in a balloon from Paris, while he was, some years ago, Mr. Edison's representative at the Paris Exposition.

Storage Batteries.

Mr. Herbert Lloyd exhibited Chloride accumulators. Cells of a special form, designed for traction purposes, as used on the Thirty-fourth street cross-town line, New York city, were shown; also oxide cells for vehicle purposes and specimen plates.

Frank Perret, J. A. Barrett and W. H. Meadowcroft exhibited a storage battery made on a unit system, whereby cells of different sizes are built up of universal units of definite capacity. Purely Planté formation is used. No oxidizing agents are employed and nothing but pure lead, sulphuric acid and water are made use of for the process of construction.

Mr. A. S. Hubbard showed the Gould storage battery as follows: (1) Positive and negative plates, having a small amount of active material, which have gone through a series of charges and discharges at half-hour and twenty-minute rates; (2) an automobile battery cell with a "spinning," giving 450 square inches of surface per pound of lead; (3) a positive and negative plate of automobile type of cell; (4) an unformed plate with delicate "spinning," giving 144 square inches per cubic inch of lead. The feature of the battery is the increase of superficial area of the plate obtained by spinning or grooving with rotary knives, which force the lead up between them, forming ribs and grooves of any desired dimensions. Each rib is made independent by tying the ends with the main cross-bars, and not depending on any center conductor or support, thus giving a low internal resistance.

Mr. Elmer A. Sperry displayed types of storage battery for automobile work, with diagrams of discharge curves.

Clarke Synchronism and Phase Indicator.

A synchronism and phase indicator for indicating when two alternating-current machines are in synchronism and the phase relations of their electromotive forces was the exhibit of Mr. Charles L. Clarke. It is also applicable for showing the lag of a current behind the electromotive force, either in the same or another circuit, provided they have equal frequencies, and also for showing the phase relations of currents of the same frequency. The instrument, as exhibited, which is intended for use in lighting and power stations, consists of two synchronous alternating-current motors, which respectively drive two stroboscopic disks, the stroboscopic image formed opposite a scale indicating when the generators respectively supplying current to the motors are in synchronism, or nearly so, and, in the latter case, which of the generators is running at the greater polar speed. When the generators are in synchronism, the stroboscopic image is stationary, and its position relative to the scale indicates the degree to which the electromotive force of one generator leads or lags behind the electromotive force of the other.

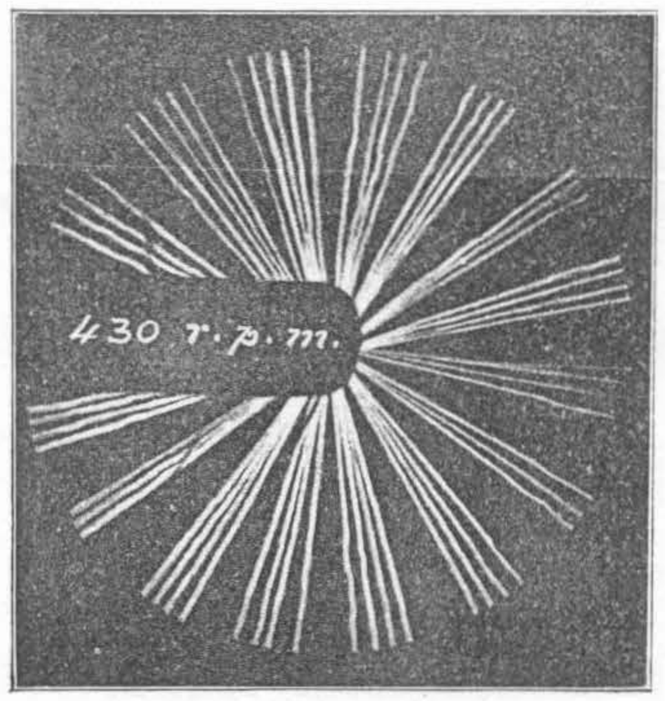

FIG. 5. THE INSTITUTE CONVERSAZIONE.—ANDREWS' SPARK EXPERIMENTS.

Miscellaneous Exhibits.

Mr. Otto T. Louis showed an electric furnace consisting of several terracotta cylinders, about two inches in diameter and one-half inch thick, around which is wound platinum wire of 22 B. & S. gauge. The wire is put on in four circuits, so that, as the resistance increases with the heat, the circuits may be thrown from series to parallel. The cylinders have longitudinal and vertical motions, and are held in position by clamps. Mr. Louis also had an ohmmeter for making direct measurements from 10,000 to 10,000,000 ohms and a 55-centimeter Wimshurst influence machine.

Other exhibits may be mentioned as follows:

Mr. E. V. Baillard.—Faradmeter and bridge for measuring low resistances.

Professor George F. Barker and Professor Arthur W. Goodspeed.—Radiographs.

Mr. A. F. Clift.—Telpherage system for the transportation of freight in small bulk, express matter, mail, etc., by means of an electric motor traveling

upon an overhead cable obtaining current by rolling contact with a lighter wire above.

Dr. Francis B. Crocker.—Magnetic liquids, with apparatus in operation for showing the magnetic properties of liquids and for measuring their permeability.

Mr. H. P. Davis.—Two switchboard panels, showing principally a phase-shifting transformer, a power-factor indicator, a synchronizer, an alternation meter and various new indicating and integrating instruments.

Professor W. S. Franklin.—Magnesia arc lamp (an electrolytic lamp on the Nernst principle, operating on 1,000 volts).

Dr. William E. Geyer.—Incandescent-lamp experiments. (Experiments employing incandescent lamps on circuits containing self-induction and capacity).

Mr. Caryl D. Haskins.—Power-factor indicator, showing relation between real and apparent energy in an alternating-current circuit, and single-coil astatic instruments, which, instead of using four coils, employ only one.

Professor Frank A. Laws.—Radiographs of alternating-current wave forms and oscillatory discharges, made by the use of cathode-ray tubes of the Braun pattern.

Colonel Samuel Reber, U. S. A.—Wireless telegraphy in operation, employing methods and improvements as worked out for the use of the United States government; also field telephone and telegraph kit used in the Cuban and Philippine campaigns.

Mr. Martin P. Rice.—New X-ray apparatus, employing a modified form of Wehnelt interrupter.

Mr. L. T. Robinson.—Wave-form indicator, consisting of a small synchronous motor in connection with suitable commutating devices, and used for determining the wave shapes of alternating current.

Mr. H. F. Sanville.—Copper-splicing machine, consisting of a portable and self-contained splicing press, with independent pump and flexible hose, used for making a solderless splice in wires and cables, forming a cold weld. This machine has an ability to give a pressure of 20 tons per square inch in the weld.

Mr. E. T. Schoonmaker.—Floating magnetic field.

Mr. Fitzhugh Townsend. — Alternating-current wave tracer. (In this device the contact is made during one-half of the period in contradistinction to the instantaneous-contact method ordinarily employed.)

A FRENCH OPINION OF TWO AMERICAN INVENTORS.

IT has recently been announced by Thomas A. Edison that by means of his magnetic ore-separator he has been able to separate hematite from magnetite, thus making it profitable to work enormous European ore deposits that do not pay with present methods and potentially blasting America's supremacy in the manufacture of steel. A representative of *The World* (New York) recently interviewed Eugene Schneider, head of the Creusot Iron Works, the most important rail, locomotive, and gun factory in France, on this subject, and reports to his paper that Mr. Schneider and his chief mining engineer expressed themselves skeptically regarding the new discovery. Mr. Schneider said:

"What is the use of discussing Edison's advertising dreams? He has no special knowledge of metallurgy, and the problems he claims to have solved have engrossed scientists all over the world.

"Let Edison occasionally do what he claims he can do and then we will be willing to give him attention. But Edison's tactics, like Tesla's, consist of finding what difficulty puzzles scientists and announcing that their own genius is about to solve it. But when the time comes neither realizes his glowing promises.

"Let it be said once and for all that real scientists all over the world consider Edison and Tesla a pair of humbugs.

"What has Edison discovered except the phonograph, which was a chance discovery and not the result of scientific perspicacity? Not electrical incandescence, for that was really invented in Germany; nor the biograph, which was discovered here by Lumiere, nor anything of real importance.

"On the other hand, has Tesla destroyed the Spanish fleet, as promised, or telephoned across the ocean, or lighted houses without wires, or entered into communication with the planet Mars?

"It is a perfect wonder that the American public, with its quick sense of humor, has not long ago shamed these two cheeky pretenders into silence."

The American technical weekly, *Electricity*, which quotes the above interview, has the following to say regarding it:

"Assuming that the above is a correct report of the interview, we think the head of the Creusot Iron Works has committed a grievous error in referring in the way he did to two such men as Edison and Tesla.

"That Edison is not a scientist every one will agree, but, on the other hand, he has given to the world invention after invention of untold value, the Frenchman's statement to the contrary notwithstanding. He did more toward perfecting incandescent electric lighting than any other investigator, invented the phonograph and gave to the world the quadruplex system of telegraphy, to say nothing of the three-wire system, the low-resistance dynamo, and innumerable other devices which have benefited the world to a greater or less extent.

"As regards Nikola Tesla, the gentleman quoted states that he is no scientist. In this we beg to differ with him, for altho it must be acknowledged that Tesla has only given the world one important invention, he is such a deep scientist and looks so far into the future that he is a century before his time. In other words, some of Tesla's ideas, which are considered by the general public as visionary dreams, will be actual facts a hundred years hence. When, therefore, a foreigner undertakes to belittle in the language quoted above two such well-known investigators and inventors as Edison and Tesla, it may safely be attributed to a feeling of envy on his part."

SYNTONIC WIRELESS TELEGRAPHY.*

BY GUGLIELMO MARCONI.

The very rapid advances which have been made in the art of telegraphy through space continue to attract much attention to this fascinating subject. What was stated yesterday to be impossible has now become possible, and what we regard as almost insurmountable difficulties may be removed in the immediate future. The number of experimenters working in this field has increased, as, many workers, who, some time ago, had little or no faith in the practical utility of wireless telegraphy, have now changed their minds and are taking up the subject. I believe it to be necessary, before I proceed to deal with the subject, to state that in my opinion a large amount of inaccurate and misleading information is being from time to time published upon it in the daily and even in the scientific press. I shall endeavour to correct some of the mis-statements which have been made.

As the title of my Paper implies, it is my intention first to describe fully the efforts I have made in order to tune or syntonise the wireless system, efforts which I am glad to say have been crowned with complete success. I also wish to mention something of the difficulties encountered in promptly publishing the results (whether successful or otherwise) obtained in the course of my experiments. A commercial concern, such as the one with which I am working, does not exist solely for the advancement of science, but especially for the purpose of securing a pecuniary return to those who have braved risks and undertaken sacrifices in assisting and forwarding the necessary experimental work. It is often considered possible that certain new methods and results may, if prematurely published before being fully patented, be utilised by persons whom I might call business rivals, thus preventing those who have borne the initial cost of the first tests from benefiting in a fair measure. I am, therefore, frequently prevented from promptly publishing the methods by which I have obtained interesting results. By quoting the dates of the British patent specifications and other publications, I hope to be able to establish, to a certain extent, the dates at which the various systems or methods were worked out. It may probably surprise some of you when I mention how comparatively long ago some of the patents which I shall discuss to-night were applied for and perfected.

Last winter I had the honour of describing before the Royal Institution of Great Britain most of the success obtained up to that date in communicating by means of my system from one place to another. It is my desire in this Paper to give a description of the further progress made, with special reference to the results obtained by tuning or syntonising the installations. So long as it was possible to work only two installations within what I may call their sphere of influence, a very important limit to the practical utilisation of the system was imposed. With simple vertical wires, as shown in Fig. 1A and Fig. 2, connected directly to the coherer and spark gap at the receiver and transmitter, as used by myself before 1898, no really satisfactory tuning was possible. It was, however, possible to obtain a certain selection of signals if various stations in the vicinity used vertical wires differing very considerably in length. Thus two stations communicating over a distance of, say, 5 miles and using wires 100ft. long, would not interfere with the signals transmitted by the other two stations, say 2 miles from the first, which were using aerials only 20ft. long, and communicating over a distance of about 1 mile. The new methods of connection which I adopted in 1898, *i.e.* (see Fig. 8), connecting the receiving aerial directly to earth instead of to the coherer, and by the introduction of a proper form of oscillation transformer in conjunction with a condenser so as to form a resonator tuned to respond best to waves given out by a given length of aerial wire, were important steps in the right direction. I referred extensively to this improvement in the discourse delivered before the Royal Institution on Feb. 2, 1900, and my first British patent specification referring thereto was applied for on June 1, 1898, No. 12,326, and published in due course. This mode of connection was also discussed by the technical press.*

It is remarkable that eminent scientists and engineers, such as Prof Slaby and G. Kapp, who have been good enough to discuss my work on wireless telegraphy, should be so badly informed on the subject in general as not to know that this method and many other improvements on my original system have been in use by myself and my assistants for several years. I wish to give you an illustration of what I mean. In a Paper on "Tuned or Multiple Wireless Telegraphy," by Prof. Slaby, of Charlottenburg, read on Dec. 22, 1900, and published in a special number of the *Elektrotechnische Zeitschrift*, he stated: "Up to the present the following method has been followed without exception:—The receiving wire was *suspended insulated and attached at the lower end to the coherer*, the other pole of which was connected to earth."

Again, G. Kapp, in an editorial review in the same publication, states:—"According to the Slaby d'Arco system and *in opposition to the Marconi system the receiving wire is earthed.*" The inaccuracy of these statements is very apparent if we compare them with the description given by myself nearly three years previously in the British patent applied for, as I have remarked, on June 1, 1898, published in July, 1899, and openly discussed by the scientific press of this and other countries a long time previous to the date of Slaby's Paper. At line 7, page 1, of my description, will be found the following passage: "According to this invention the conductor (aerial) *is no longer insulated, but is connected to earth* through the primary of an induction coil, whilst the ends of the imperfect contact (or coherer) are connected to the ends of the secondary one of the connections passing through a condenser." As you will notice, nothing is said in this patent of the necessity of insulating the vertical wire of the receiver. If the system described here had not been used by me I very much doubt whether we should have succeeded in maintaining communication with the East Goodwin lightship during 1899, in maintaining communication across the English Channel that same year during the meeting of the British Association at Dover, and in supplying the Admiralty in the course of the year 1900 with 32 installations, all of which passed an official 100 kilometre test (most of the distance being over land) at the rate of about three installations per week.

Leaving this subject for the present, I shall endeavour to describe the various steps made in the development of my syntonic system. I realised a long time ago that one great difficulty in achieving the desired effect was caused by the action of the transmitting wire. A simple straight rod in which electrical oscillations are set up forms, as is well known, a very good radiator of electrical waves. If this was in the beginning an advantage, by allowing signals to be received with a small amount of energy over considerable distances, it proved later to be one of the chief obstacles in the way of obtaining good resonance in the receiver. Now, as Dr. Fleming points out so clearly in his Cantor lectures on "Electrical Oscillations and Electric Waves," delivered before this Society in November and December of last year, there is in connection with this part of the subject one point of great interest. "Both theoretical and experimental research show that in the case of conductors of a certain form the electric oscillations die away with great rapidity." In all what we call good radiators, electrical oscillations set up by the ordinary spark discharge method cease, or are damped out very rapidly, not necessarily by resistance, but by electrical radiation removing the energy in the form of electric waves. Many mechanical analogies can be quoted which will point out the necessity of designing a persistent oscillator, in order that syntony may become apparent in properly tuned resonators. Acoustics furnish us with numerous examples of this fact, such as the resonance effects produced by the well-known tuning-fork experiment. Other illustrations of this principle may be given, *e.g.*, if we have to set in motion a heavy pendulum by means of small thrusts or impulses, these must be timed to the period of oscillation of the pendulum, since otherwise its oscillations will not acquire any perceptible amplitude. An illustration of this fact occurred to me some time ago while I was watching the ringing of

* Paper read before the Society of Arts, May 15.

* See *The Electrician*, Vol. XLIII., p. 48; also Vol. XLIV., pp. 555–556.

great bells in an Italian cathedral. As most of you probably know, the bells in many churches in Italy, as elsewhere, are rung from the bottom of the tower by means of ropes attached to the bells. The largest bells weigh several tons, and it usually requires two men to work for perhaps two minutes on the ropes before the combined effect of their pulls is sufficient to get the bell to attain an amplitude large enough to cause the hammers to strike. I observed on the occasion to which I allude that it required for each bell a number of well-timed pulls on the ropes in order to get them to swing, the larger bells requiring impulses further apart, *i.e.*, of a lower frequency, than the smaller ones. It is perfectly obvious that if the pulls on the ropes had been wrongly timed it would have been impossible with the same amount of power to ring the bells. The same kind of effect happens in a very small fraction of a second (instead of several minutes) when we try to induce electrical oscillations in a good resonator. If the form of this resonator be such as to cause it to be a persistent vibrator, *i.e.*, one in which the electrical oscillations are not rapidly damped by resistance or radiation of waves, then it is necessary for us to employ a number of properly timed electrical oscillations radiated from a persistent oscillator tuned to the period of the resonator we desire to affect.

As I pointed out before, a transmitter consisting of a vertical conductor as shown in Fig. 1 is not a very persistent oscillator.. Its electrical capacity is comparatively so small and its capability of radiating waves so great, that the oscillations which take place in it must be considerably damped. In this case receivers or resonators of a considerably different period or pitch will respond and be affected by it. From the results obtained it would seem as if the transmitter were sending out a great variety of electric waves, resembling therefore a source of white light, and that each resonator picks out and responds to its own particular wave length. This view, however, is incorrect ; the fact that, given certain conditions,

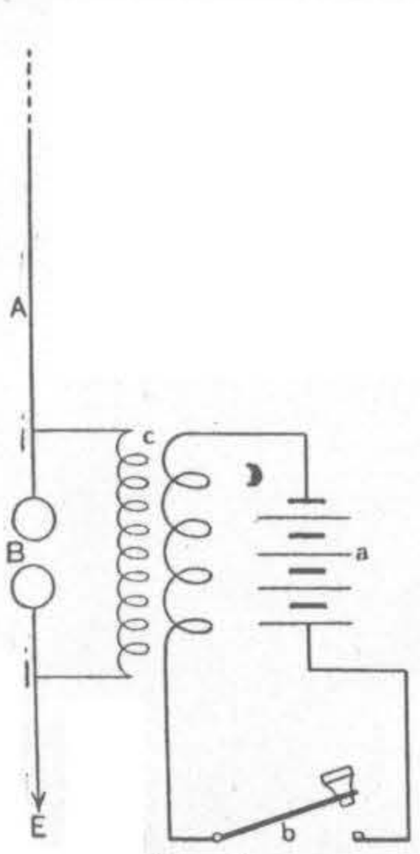

FIG. 1.

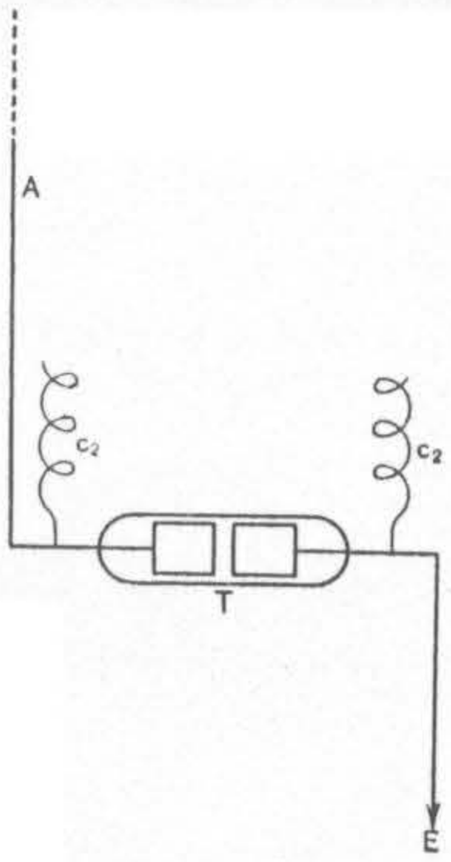

FIG. 2.

various resonators will respond, even if their period be different from the natural period of oscillation of a transmitter, is to be accounted for by the consideration that all the energy of the transmitter is radiated in only one or two swings, with the result that oscillations may be induced in resonators of different periods, whilst, if the same amount of energy be distributed in a great number of individual feeble impulses, their combined effect can only be utilised or detected by a resonator tuned so as to respond to their particular frequency. The tuned resonator will not then respond to the first two or three oscillations but only to a longer succession of properly timed impulses, so that only after an accumulation of several swings does the E.M.F. becomes sufficient to break down the insulation of the coherer, and cause a signal to be recorded.

Notwithstanding the disadvantages for obtaining electrical tuning, attributed to the form of transmitter shown in Fig. 1, selection of messages is possible when using, say, two or three transmitters having wires of considerably different lengths, and the induction coil or oscillation transformers on the receivers wound with varying lengths of wire in their secondary circuits, in order to cause them to be in tune or resonance with the length of wave of the transmitted oscillations, as pointed out in my British patent, No. 12,326, dated June 1, 1898. At page 1, line 19, this reads : "It is desirable that the induction coil should be in tune or syntony with the electrical oscillations transmitted, the most appropriate number of turns and most appropriate thickness of wire varying with the length of wave transmitted." The following experiment, which has been successfully tried, proves this point. At St. Catherine's, Isle of Wight, we had a transmitting station having a vertical wire 45 metres long, and at sea, 10 miles from our receiving station at Poole, a ship with transmitting wire of 27 metres. It is, therefore, obvious that the wave length of the electric oscillations radiated from St. Catherine's differed considerably from that radiated from the ship. Now, if at the receiving station at Poole we connected to a vertical wire two receivers, one having an induction coil with secondary in tune with the length of wave emitted by St. Catherine's and the other with that emitted by the 27-metre feet wire on the ship, if St. Catherine's and the ship transmit simultaneously two different messages, these will be picked up at Poole, and each message will be reproduced distinctly on its receiver. I pointed out in a patent specification dated Dec. 19, 1899, No. 25,185, page 2, that the best results are obtained when the length of wire of the secondary of the induction coils is equal to the length of the vertical wire used at the transmitting station, therefore the length of the secondary of the receiving induction coils was made equal to that of the transmitting wire. (Something of the same kind has been lately noticed by Prof. Slaby in what he calls an extension wire.)

These results, although in a way satisfactory, did not appear to my mind a complete solution of the problem. I found it impossible to obtain the two messages at the receiving station if the two transmitting stations were placed at equal distances from it. The following considerations may perhaps explain this failure. If the 27-metre transmitting wire was placed at the same distance from Poole as the 45-metre one, *i.e.*, 31 miles, the waves emitted by the 27-metre wire would be too weak when they reached Poole to affect the receiver. On the other hand, if the 45-metre transmitter was placed at 10 miles from the receiver, then the waves radiated by it would be so strong as to affect the receiver, tuned to respond to the 27-metre transmitter, and blur its signals.

It thus became apparent that some different form of less damped radiator was necessary in order to obtain more practical and more useful results. I carried out a great number of experiments by adding

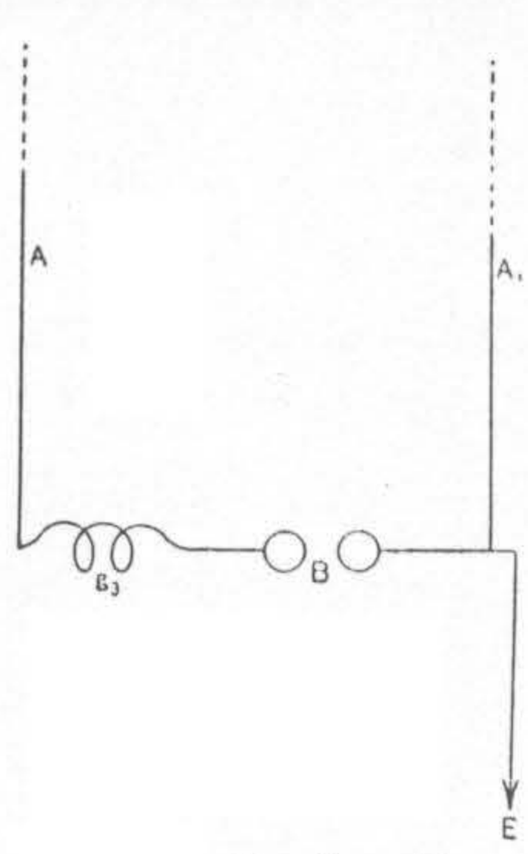

FIG. 3.

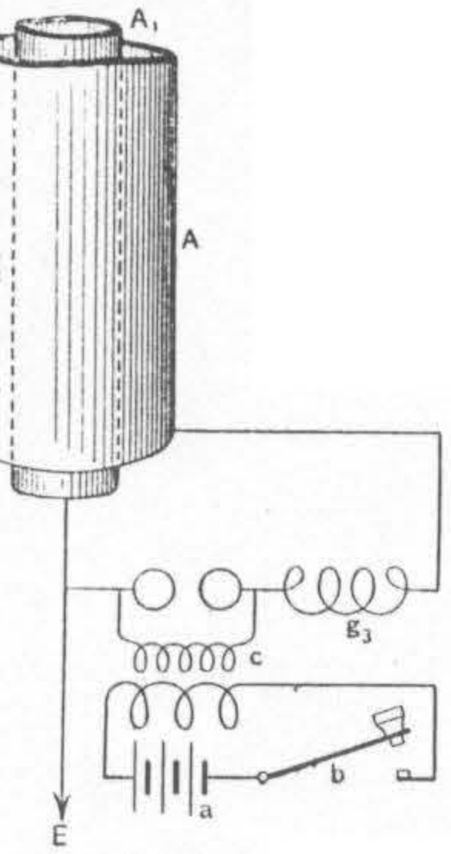

FIG. 4.

to the radiating and receiving wires inductance coils, on a principle similar to that suggested by Lodge in his 1898 patent (No. 29,069), but without obtaining any satisfactory results. The failure was probably due to the fact that the electrical capacity of the exposed conductors became too small in proportion to their inductance. I then tried various methods for increasing the capacity of the radiating system. The first and obvious mode of effecting this is by an augmentation in the size of the exposed conductor, but this method is not entirely satisfactory, in consequence of the circumstance that an increased surface means increased facility for radiating the energy during the first oscillations, and also because large plates or large exposed areas are impracticable on board ship, and are always difficult to suspend and maintain in good position during windy weather. The way out of the difficulty was discovered by adopting the arrangement shown in Fig. 3. Here we have an ordinary vertical radiator placed near an earthed conductor, the effect of the adjacent conductor being obviously to increase the capacity of the electrical radiating wire without in any way increasing its radiative power, and, as I had expected, syntonic results were not difficult to obtain with such an arrangement. Mention of this method has been made by Capt. Ferrie, one of the members of the French Commission which was present at the tests carried out across the English Channel in 1899, in a Paper on wireless telegraphy. See Paper "Etat Actuel et Progrès de la Telegraphie Sans Fil," read before the Congrès International d'Electricité, Paris, 1900.* Satisfactory results were obtained, and I was encouraged to continue my researches in order to improve the system. Early in 1900 I obtained very good

* See *The Electrician*, Oct. 26. 1900, p. 22 ("Electrician" Publishing Co.).

results with the arrangement shown in Fig. 4. This arrangement is fully described in a British patent application applied for by myself on March 21, 1900, No. 5,387. In it the radiating and resonating conductors take the form of a cylinder, the earthed conductor being placed inside. This form of radiating and receiving areas is much more efficient than the one I have previously described. One necessary condition of this system is that the inductance of the two conductors should be unequal, it being preferable that the large inductance should be joined to the non-earthed conductor. I presume that, in order to radiate the necessary amount of energy, it is essential that there should be a difference in phase of the oscillations in the two conductors, as otherwise their mutual effect would be to neutralise that of each other. In the first experiments mentioned by Capt. Ferrie this was obtained by simply using an earthed conductor shorter than the radiating or resonating one. When I used an inductance between the spark-gap or oscillation producer and the radiating conductor, I found it possible to cause the electrical period of oscillation of the receiving cylinder to correspond to that of one out of several transmitting stations, from which one alone it would receive signals. The results obtained by this system have been remarkable. By using cylinders of zinc only 7 metres high and 1·5 metres in diameter, good signals could easily be obtained between St. Catherine's, Isle of Wight, and Poole (distance 31 miles), these signals not being interfered with or read by other wireless telegraph installations worked by my assistants or by the Admiralty in the immediate vicinity. The closely adjacent plates and large capacity of the receiver cause it to be a resonator possessing a very decided period of its own, *i.e.*, it becomes no longer apt to respond to frequencies which differ from its own particular period of electrical oscillation, nor to be interfered with by stray ether waves, which are sometimes probably caused by atmospheric disturbances, and which occasionally prove troublesome during the summer. It seemed very remarkable to me during my first

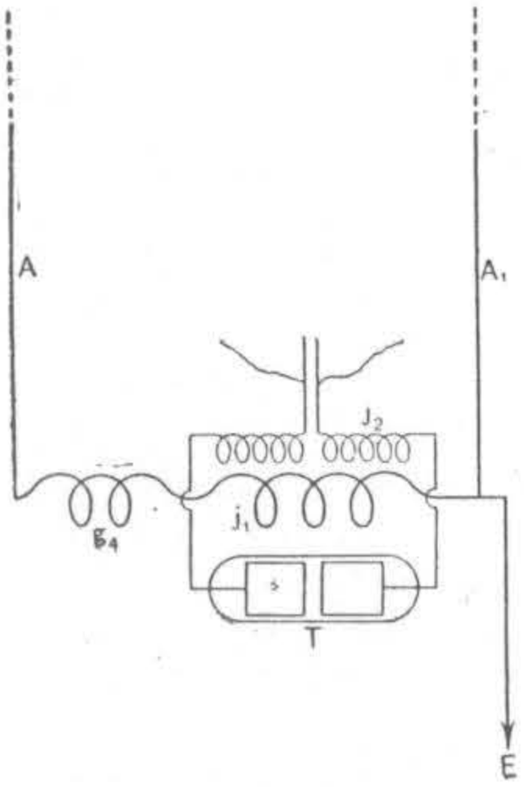

FIG. 5.

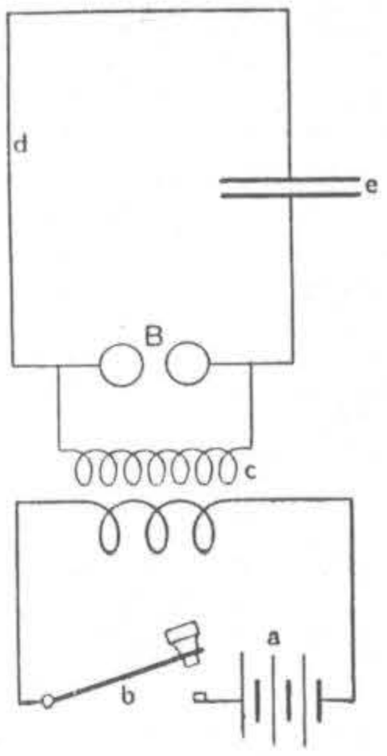

FIG. 6.

test that an arrangement similar to that shown in Fig. 4 should prove to be a good radiator and should enable such a considerable distance to be achieved with cylinders of so moderate a height. It is probable that the great majority of the electrostatic lines of force pass directly from one cylinder to the other, but it must be also true that a certain number leave the outer part of the external cylinder, exactly as in the case of an ordinary radiator. The receiver is not shown in the sketch, but consists of similar cylinders to those used for transmitting the receiving induction coil or oscillation transformer, being placed where the spark-gap is shown in Fig. 4. The capacity of the radiator due to the internal conductor is, however, comparatively so large that the energy set in motion by the spark discharge cannot all radiate in one or two oscillations, but forms a train of slowly damped oscillations, which is just what is required. A simple vertical wire, as shown in Fig. 1, may be compared with a hollow sphere of thin metal which, when heated, would cool very rapidly, and the concentric cylinder system with a solid metal sphere, which would take a very much longer time to cool. Mr. W. G. Brown suggested, in a patent specification dated July 13, 1899, No. 14,449, the use of two conductors of equal length joined to each side of the spark-gap, but he did not describe the inductance in series between them and the spark-gap, which, according to my experience, is absolutely essential for long-distance work. Another very successful syntonised transmitter and receiver system was the outcome of a series of experiments carried out with the discharge of Leyden jar circuits. Taking for granted that the chief difficulty with the old system, as shown in Fig. 1, lies in the fact, as already stated, that the oscillations are very dead beat, I tried by means of associating with the radiator wire a condenser circuit, which was known to be a persistent oscillator, to set up a series of persistent oscillations in the transmitting vertical wire.

An arrangement as shown in Fig. 6, which consists in a circuit containing a condenser and a spark-gap, constitutes a very persistent oscillator. Prof. Lodge has shown us how, by placing it near another similar circuit, it is possible to demonstrate interesting effects of resonance by the experiment usually referred to as that of Lodge's syntonic jars. But, as Lodge points out,* "A closed circuit such as this, is a feeble radiator and a feeble absorber, so that it is not adopted for action at a distance." I very much doubt if it would be possible to affect an ordinary receiver at even a few hundred yards. It is very interesting to notice how easy it is to cause the energy contained in the circuits of this arrangement to radiate into space. It is sufficient to place near one of its sides a straight metal rod or good electrical radiator. The only other condition necessary for long-distance transmission is that the period of oscillation of the wire or rod should be equal to that of the nearly closed circuit.

Stronger effects of radiation are obtained if the radiating conductor is partly bent round the circuit, including the condenser (so as to resemble the circuits of a transformer). I first constructed an arrangement as shown in Fig. 14, which consists of a Leyden jar or condenser circuit, in which is included the primary of what may be called a Tesla coil, the secondary of which is connected to the earth or aerial conductor. The idea of using a Tesla coil to produce the oscillations is not new. It was tried by the Post Office officials when experimenting with my system in 1898, and also suggested in a patent specification by Dr. Lodge, dated May 10, 1897, No. 11,575, and by Prof. Braun in the specification of a patent dated Jan. 26, 1899, No. 1,862. My idea was to associate with this compound radiator a receiver tuned to the frequency of the oscillations set up in the vertical wire by the condenser circuit. My first trials were not successful, in consequence of the fact that I had not recognised the necessity of attempting to tune to the same period of

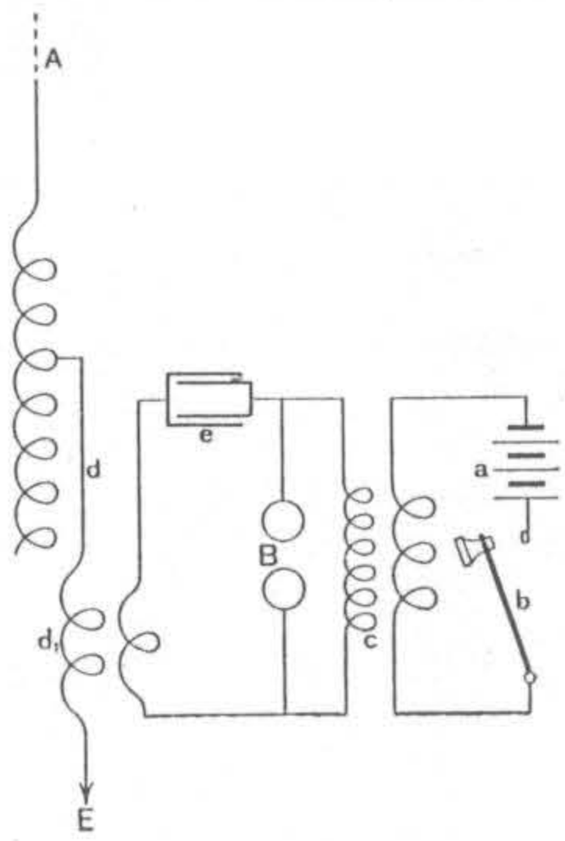

FIG. 7.

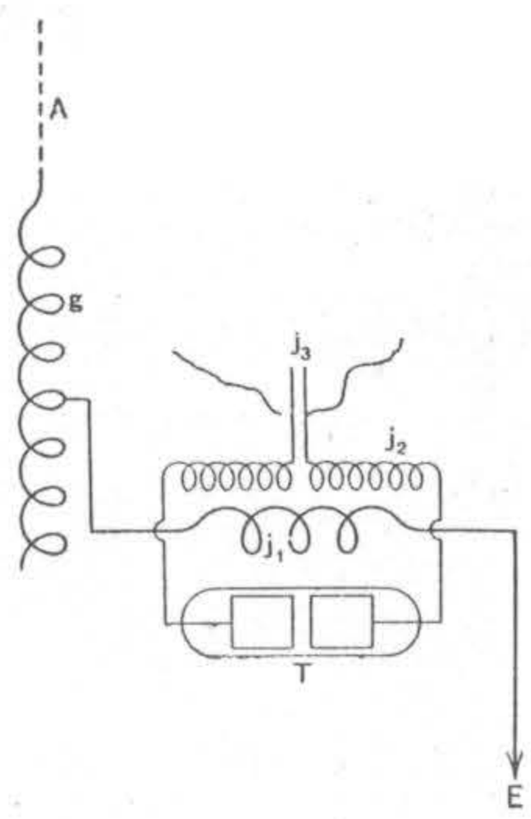

FIG. 8.

oscillation (or octaves) the two electrical circuits of the transmitting arrangement (these circuits being the circuit consisting of the condenser and primary of the Tesla coil or transformer, and the aerial conductor and secondary of the transformer). Unless this condition is fulfilled, the different periods of the two conductors create oscillations of a different frequency and phase in each circuit, with the result that the effects obtained are feeble and unsatisfactory on a tuned receiver. The syntonised transmitter is shown in Fig. 7. The period of oscillation of the vertical conductor A can be increased by introducing turns, or decreased by diminishing their number, or by introducing a condenser in the series with it. The condenser C in the primary circuit is constructed in such a manner as to render it possible to vary its electrical capacity. The receiving station arrangements are shown in Figs. 8 and 9. Here we have a vertical conductor connected to earth through the primary of a transformer, the secondary circuit of which is joined to the coherer or detector. In order to make the tuning more marked, I place an adjustable condenser across the coherer in Fig. 9. Now, in order to obtain the best results, it is necessary that the free period of electrical oscillations of the vertical wire primary of transformer and earth connection should be in electrical resonance with the second circuit of the transformer, which includes the condenser. I stated that, in order to make the tuning more marked, I placed a condenser across the coherer. This condenser increases the capacity of the secondary resonating circuit of the transformer, and in the case of a large series of comparatively feeble but properly timed electrical oscillations being received, the effect of the same is summed up until the E.M.F

* "The Work of Hertz," by O. J. Lodge, page 7.

at the terminals of the coherer is sufficient to break down its insulation and cause a signal to be recorded.

In order that the two systems, transmitter and receiver, should be in tune, it is necessary (if we assume the resistance to be very small or negligible) that the product of the capacity and inductance in all four circuits should be equal. A more complete and detailed description of this system is given in a British patent granted to me, dated April 26, 1900, No. 7,777. I have recently found that Prof.

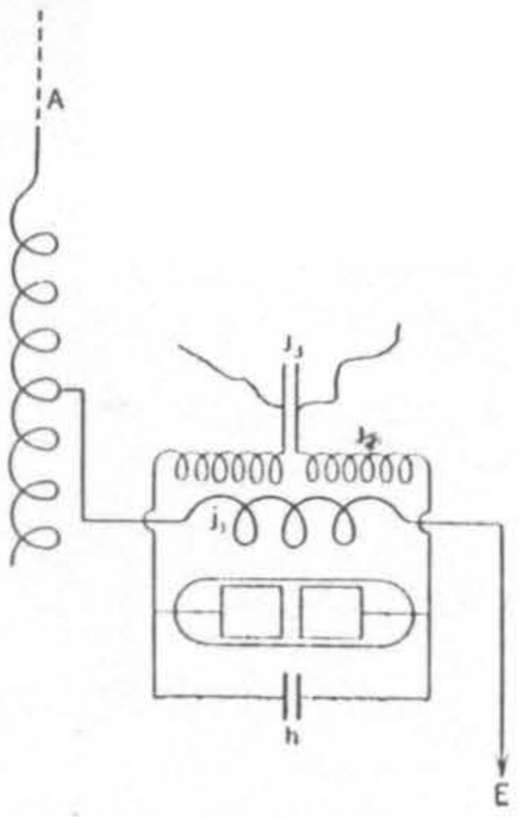

FIG. 9.

Braun has recognised the necessity of tuning the circuits of the transmitter and receiver when using a Tesla coil in order to obtain syntonic effects, but I am not aware that such a proposal was published prior to the description given in the above-mentioned patent.

Although little difficulty has been encountered in measuring the capacity used in the various circuits, the measurement or calculation of the value of the inductance is not so easy. I have found it impracticable by any of the methods with which I am acquainted

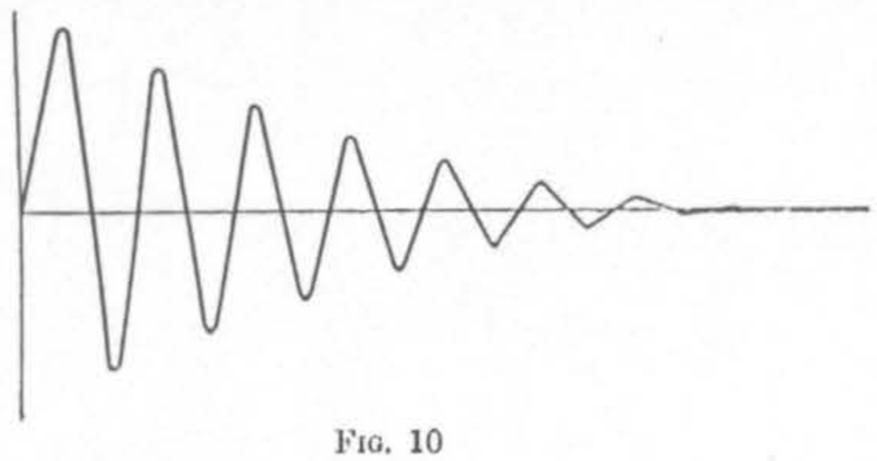

FIG. 10

directly to measure the inductance of, say, two or three small turns of wire. As for calculating the inductance of the secondary of small transformers, the mutual effect of the vicinity of the other circuits and the effects due to mutual induction greatly complicate the problem.

Experiments have confirmed the fact that the receiving induction coils having the secondary wound in one layer and at a certain distance, say 2mm. (to cause the capacity to be so small as to be negligible), have a time period approximately equal to that of a vertical conductor of equal length

FIG. 11.

(see patent granted to G. Marconi, dated Dec. 19, 1899, No. 25,186). If, therefore, we are using an induction coil having a secondary 40 metres long on the receiver, I should use a vertical wire 40 metres long at both transmitting and receiving stations. By so doing I have the two circuits at the receiving station in tune with each other, and I only have to adjust the capacity of the condenser at the transmitter, which can easily be done, either by means of a condenser having movable plates that can be slid, more or less, over each other, or by adding or removing Leyden jars.

If we start with a very small capacity which we gradually increase, a value of the capacity will be reached which will cause signals to be recorded on the receiver. Supposing the receiving system to be within the sphere of action of the transmitter, then the signals will be strongest when the capacity of the condenser is of a

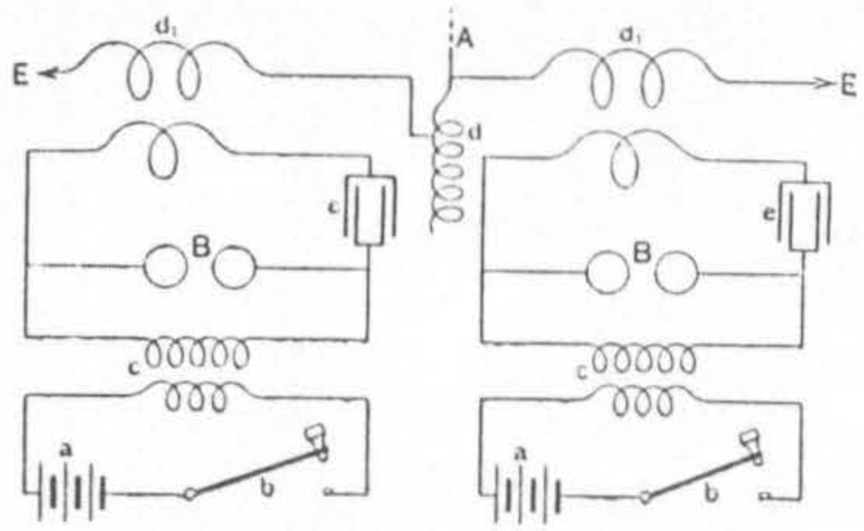

FIG. 12.

certain value. If we still increase the capacity, the signals will gradually die away, whilst if we go on increasing the capacity, and, at the same time, add inductance to the aerial, to keep it in tune with the condenser jar circuit, we are still radiating waves, but these do not affect the receiver. If, however, at the receiving station we

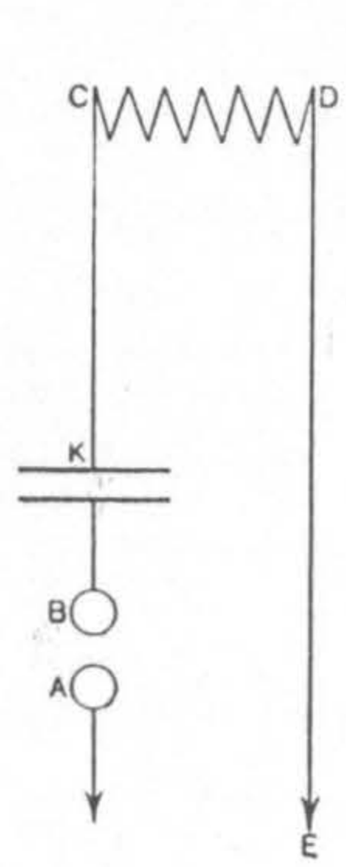

FIG. 13.

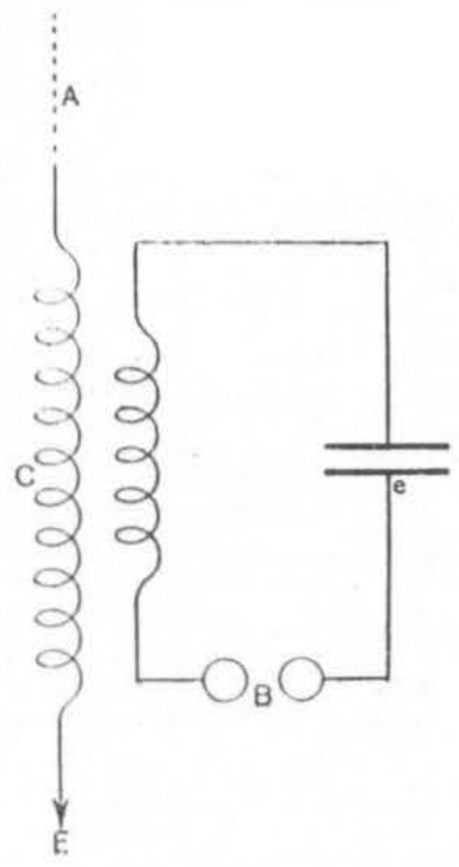

FIG. 14.

add inductance or capacity to the wire A, Fig. 9, and also to the ends of the secondary of J 2, we find ourselves able to receive messages from the transmitter although we are utilising waves of a different frequency.

(To be concluded.)

SYNTONIC WIRELESS TELEGRAPHY.*

BY GUGLIELMO MARCONI.

(*Concluded from page 175.*)

It is easy to understand that if we have several receiving stations, each tuned to a different period of electrical vibration, and of which the corresponding inductance and capacity at the transmitting station are known, it will not be difficult to transmit to any one of them without danger of the message being picked up by the other stations for which it is not intended. But, better than this, we can connect to the same vertical sending wire, through connections of different inductance, several differently tuned transmitters, and to the receiving vertical wire a number of corresponding receivers. Different messages can be sent by each transmitter connected to the same radiating wire simultaneously, and received equally simultaneously by the vertical wire connected to differently tuned receivers. This result, which I believe to be quite novel, I showed to several friends of mine, including Dr. Fleming, F.R.S., in the summer of last year, and to an Admiralty Commission. Dr. Fleming has made mention of the results I showed him, in a letter to *The Times*, dated Oct. 4, 1900, and in his Cantor lectures delivered before the Society of Arts in November and December, 1900. A further improvement has been obtained by the combination of the two systems. In this case the cylinders are connected to the secondary of the transmitting transformer, and the receiver to a properly tuned induction coil, and all circuits must be tuned to the same period as already described. (See Fig. 16.)

The tuning of the receiver to respond to the period of the transmitter, as used in the old form of transmitter shown in Fig. 1, or in the new one shown in Fig. 7, has enabled results to be obtained over considerable distances with moderate heights. As already published by Dr. Fleming in the letter above referred to, signalling has been successfully carried out over a distance of 50km. with a cylinder only 1·25 metres high, 40in. in diameter. This has led to the possibility of constructing portable apparatus for army purposes which should be of great service in the field. I have succeeded in constructing a complete installation on a steam motor car. On the roof of the car there is placed a cylinder which can be lowered when travelling, its height being only 6 or 7 metres, and by this means communication has been easily carried out with a syntonised station over a distance of 31 miles. A 25cm. spark induction coil worked by accumulators and taking about 100 watts is used for transmitting, and the accumulators can be re-charged by a small dynamo worked by the car motor. I believe such an appliance might have been of use to the besieged garrisons in South Africa and China. A strip of wire netting laid on the ground is sufficient for earth connection, and by dragging it along communication can be established even when the car is travelling. I have recently obtained as good results by not using any "connection" to earth, but only utilising in lieu of earth the electrical capacity of the boiler of the motor car. I also find that signals can be transmitted a considerable distance with the cylinder in a horizontal position.

Last spring I recognised the desirability of carrying out tests between stations situated at much greater distances apart than had been attempted heretofore.† A station was established at the Lizard, Cornwall, and on the first attempt communication was effected with St. Catherine's, Isle of Wight, over a distance of 186 miles, which, I believe, is the record distance over which signals have been sent through space without wires. It is interesting to observe that signals were obtained over this distance with the transmitting apparatus as shown in Fig. 1, or with the arrangement shown in Fig. 7, provided always that a suitable resonating induction coil was employed at the receiving station. The amount of energy used for signalling over this distance is not more than 150 watts, but experiments with a larger amount of energy will shortly be carried out. In the case of the 186 miles transmission, the aerial conductor consisted of four parallel vertical wires 1·50 metres apart, 48 metres long, or in a strip of wire netting of same length. It is interesting to note that in order to communicate between my stations at Poole and St. Catherine's (distance 31 miles) with the same amount of energy and the same kind of aerial wire this must be 20 metres high to obtain signals of about the same strength as those obtained between the 186-mile stations with the 48-metre aerials. This goes to confirm many other results previously obtained, which indicate that with a parity of other conditions the distance varies with the square of the height of the vertical conductors at the two stations. I have always found this law fulfilled, if the height of the conductors at the two stations is approximately equal, although an attempt has been made recently to throw doubt upon its correctness.

You will admit that the progress achieved in syntonic space telegraphy must have enormously increased its field of application and usefulness, since a very great number of non-interfering stations can now be worked in the immediate vicinity of each other. It will probably be of interest if I give you a few examples of the progress made in the practical utilisation of my system. An eminent electrician recently expressed a doubt whether there was at present a single circuit worked commercially on a practical system of wireless telegraphy.* If earning a revenue from working installations can be termed a commercial working, even such an incomplete list of these as time will now permit me to give you, and which are now all in permanent working order, may be sufficient proof that a beginning at least has been made in the commercial utilisation of the system.

In March, 1900, there were in use in the Royal Navy in South African waters, five installations of my system. The Admiralty was apparently well satisfied with its working, since in May of last year they decided to extend its adoption to 32 more ships and land stations. The conditions of the contract were that each apparatus before being accepted should be satisfactorily worked by naval signalmen between two ships anchored at Portsmouth and Portland, over a distance of 62 miles, a considerable portion of which—*i.e.*, 18 miles—lies over land, with intervening hills, and the height of aerial wire was specified not to exceed on each ship 49 metres. The apparatus was delivered in a comparatively short time, no sets having been found unsatisfactory. The apparatus supplied to the Admiralty is, so far, all of the old pattern—*i.e.*, the non-syntonised system; and I have been informed that messages have been transmitted and received by naval signalmen between ships more than 160km. apart. It sometimes occurs that the unfamiliarity of the operators with the particular kind of apparatus used caused unsatisfactory results to be obtained, but I believe this trouble will soon disappear. I am glad to be able to state that arrangements are being made to instal my new syntonic apparatus upon several of His Majesty's ships. I believe that in no other navy in the world is wireless telegraphy being worked regularly over such considerable distances. My system is also used for communication between the Borkum riff and Borkum lightship in Germany, where an ordinary commercial charge is made for messages received from ships, and it is employed, further, on the Nord Deutscher Lloyd's mail steamer "Kaiser Wilhelm der Grosse."

According to an official report of the imperial postal authorities of Oldenburg, the total number of commercial wireless telegrams transmitted from and to the lightship between May 15 and the end of October amounted to 565, and of these 518 came from ships at sea, whilst 47 were transmitted to ships. Of the 518 telegrams, 35·7 per cent. were addressed to the North German Lloyd and 64·3 per cent. to other shipping firms. The installations are worked by ordinary operators in a most satisfactory manner, and on one occasion, assistance was obtained for a man who was taken suddenly ill on the Borkum riff, and it was thus made possible to hand him over promptly for medical treatment on shore.

The system has been in operation at La Panne, near Ostend, and on the Belgian mail steamer, "Princess Clémentine," which plies to Dover. With a height of only 22 metres on the ship it has been found practicable to communicate from Dover Harbour to La Panne, 43 miles away, and this installation has proved of value in saving life and property. Thus, recently, a barque was wrecked on the Rattel bank. The "Princess Clémentine," which happened to pass near, at once sent a message to Ostend, and, before leaving, was able to tell the shipwrecked sailors that assistance was on the way. The men were all saved.† On another day, coming within sighting distance of the Ruytingen lightship, situated about 15½ miles from Dunkirk, the captain of the "Princess Clémentine"

* Paper read before the Society of Arts, May 15.

† See *The Electrician*, Feb. 15, 1901, p. 609.

* See *The Electrician*, Nov. 30, 1900, page 211, and editorial article, page 205.

† See *The Electrician*, March 15, 1901, p. 267.

observed that he was being signalled. It appears that the lighting apparatus of the Ruytingen had got out of order. The captain of the mail packet immediately despatched a message, which was received by the installation at La Panne, and repeated to the lighthouse department at Dunkirk. A crew immediately set out for the lightship and effected the necessary repairs, and the great inconvenience and danger of the lightship not being able to have the lights in order was averted.

Another instance of the usefulness of the wireless telegraphy in an emergency was furnished when the "Princess Clémentine" herself went ashore on the Belgian coast during a fog. Within a few minutes of the accident news of it was telegraphed from the stranded ship to Ostend, with the result that a tug was at once despatched to her assistance, and she got off at the next high tide. So successful has the installation of wireless telegraphy been on the

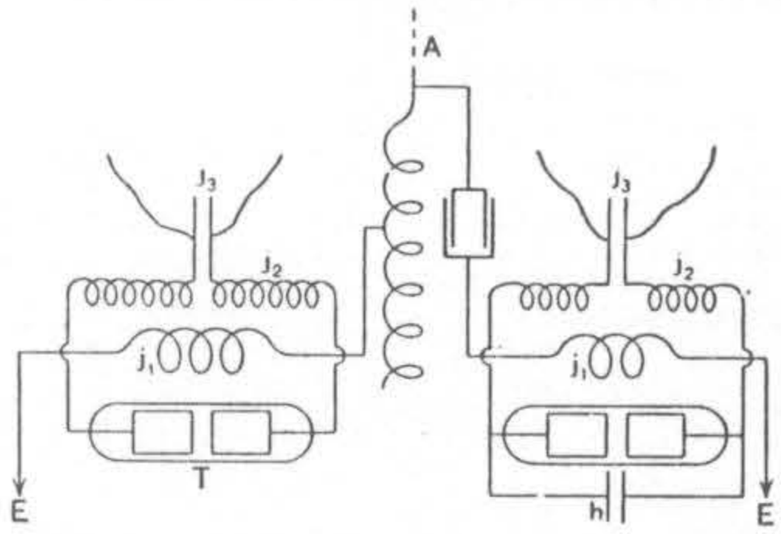

FIG. 15.

mail steamer "Princess Clémentine," between Dover and Ostend, that similar apparatus is to be fitted on the other vessels of the same fleet.

The system has been in use, furthermore, since March 1 last for ordinary commercial telegraphy between the Sandwich Islands, where a regular charge is made for the same. An installation has also been successfully carried out by my assistants for the French Government between Antibes, in France, and Corsica, a distance of 124 miles.

As has already been published in the daily papers, much use has been made of my system in the Navy during the voyage of the Duke and Duchess of Cornwall and York to Australia.

I have tried lately to ascertain how near a tuned transmitter which is radiating waves of a certain frequency must be to a receiver

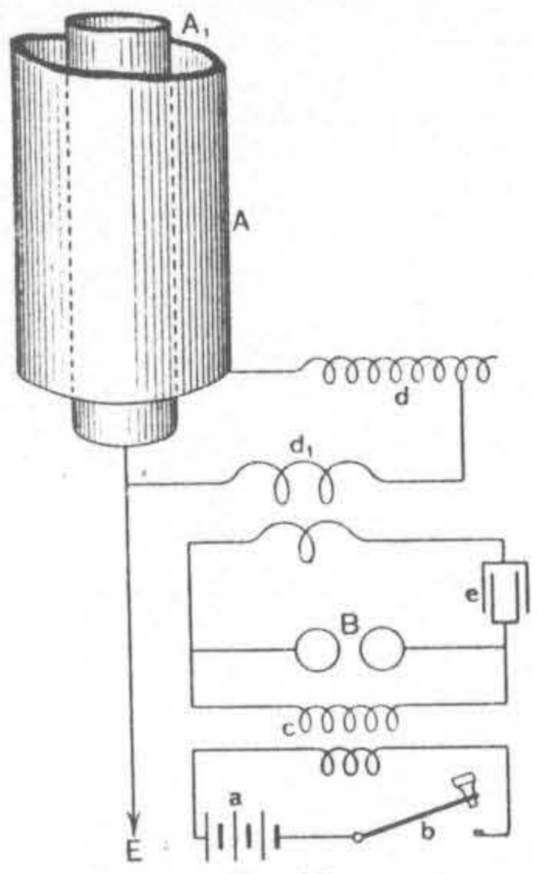

FIG. 16.

tuned to a different frequency in order that the said receiver shall be affected. I find that if we are working with oscillations which differ very considerably in period, a transmitter capable of sending signals 31 miles to a tuned receiver will not affect a non-tuned one at 50 metres. If the periods of oscillation of the two tunes are more similar to each other, then the non-tuned receiver may be affected even at several kilometres.

Considerable use is still made of the non-tuned system at my experimental stations, in order to be able to communicate with ships fitted with what I call the old system, and also in order to be able to communicate with the naval station at Portsmouth.

Before concluding, I wish to say a few words on a method proposed by Prof. Slaby, and with which I have also carried out some experiments. As transmitter, Slaby uses an arrangement as shown in Fig. 13, which consists of a vertical conductor, in which is interposed a condenser K and a spark-gap B. The top of the wire is not free, but is connected to earth through an inductance CD and a wire E. At the receiving station the arrangement shown in Fig. 17 is employed. It consists in a vertical conductor DC, connected to earth at C, which should be the nodal point of the waves induced in the wire DC, where there is joined another wire, termed an extension wire, of equal length. In this case Slaby places an apparatus which he calls a "multiplicator," connected to the coherer between the end of the extension wire and the earth, or by another arrangement (Fig. 17); he uses a loop wire FGHDCE, the multiplicator being placed between E and F in series with the extension wire J. By means of this arrangement, Slaby, on Dec. 22 of last year, showed the reception of two different messages sent from two transmitting stations situated at unequal distances from the receiving station to be possible, one station being at 4km. and the other at 14km., thus obtaining a result which may be considered similar to that obtained by me some months previously over larger distances (see Prof. Fleming's letter in *The Times* of Oct. 4, 1900). The information given in Slaby's Paper, as published in the *Elektrotechnische Zeitschrift*, is exceedingly incomplete. We are not told what was the amount of energy used for the transmission nor the height of the vertical conductor at the receiving station or at the transmitting station at the Aberspree Kablewurks. We are told that the transmission wire was suspended between the chimney shafts. Very little information is given as to the appliance which Dr. Slaby calls a multiplicator. G. Kapp, who is probably acquainted with the details of Slaby's work, commenting on this Paper of his, calls the instrument in question "an especially wound induction coil ('induction-spule') the function of which is to increase the E.M.F. of the oscillations at the ends of the coherer." Upon reading this for the first time, I assumed that the multiplicator was an oscillation transformer performing the function of those described in my patent dated June 1, 1898, and also described in my Royal Institution lecture of Feb. 2, 1901. As I subsequently, however, discovered, Prof. Slaby, referring to the multiplicator, states :—"This apparatus in its most simple form consists of a wire coil of a determined shape and form of winding,

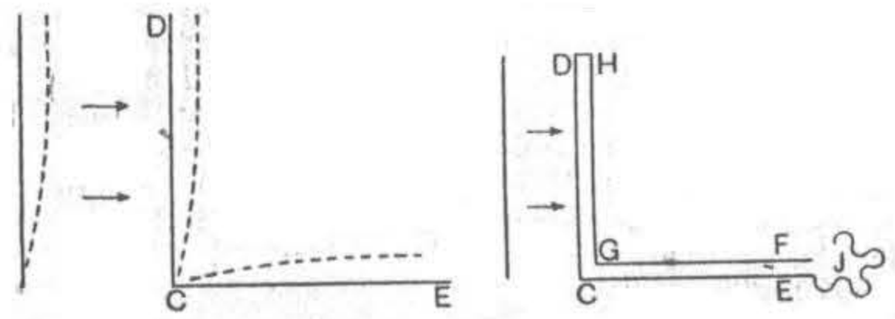

FIG. 17.

which depends upon the length of the wave. . . . I might call this apparatus, unknown to my knowledge up to the present, a multiplicator. It is not to be confounded with a transformer, as it has no secondary winding."

This statement appears to me very ambiguous, as I always have understood that what we call transformers need not have a distinct secondary winding. An appliance called an auto-transformer was used by the Westinghouse Company for regulating the E.M.F. supplied to house lighting installations, which consisted in a single winding, a certain number of turns acting inductively on the adjacent ones. (See "The Alternate-Current Transformer," by J. A. Fleming, Vol. II, pp. 187, 188.) One of the first transformers ever made is shown in the work above referred to, Vol. II., pp. 6 and 7. At page 6 we read :—"Page really made the first experiment in auto-induction and showed that different parts of the same conductor might act as primary and secondary circuits to each other, if in contiguity."

I installed the apparatus described by Slaby at Niton, Isle of Wight, and at Poole, using wires 35 metres high, but with the receiving wire earthed at C (Fig. 17) of the loop I could receive nothing although I tried various frequencies of oscillation. It is, however, probable that I might have received, had I been working over much shorter distances than 50km., as Slaby did in his demonstration, or had I used a greater height of wire. By using, however, my method of connection—*i.e.*, introducing between the vertical wire and earth an oscillation transformer having its circuits tuned to the frequency given by an ordinary vertical radiating conductor of length equal to the Slaby wire AC. I succeeded by means of extremely sensitive coherers in obtaining communication. I then tried the following experiment :—I took down the earth wire ED, and the inductance DC, and used only the conductor AC insulated, with the condenser in circuit for transmitting. An enormous strengthening of the signals at the receiver was immediately obtained, which obviously means a greater ease of working, and the possibility of obtaining signals over greater distances. The reasons which demonstrate that a closed circuit, such as is employed by Slaby, must be a poor radiator, are obvious to those who have studied and read the classical works published since the time of Hertz's experiments.

Dr. Slaby, however, states that the inductance at the top of his loop confines the oscillations to the vertical part AC. If this be the case, the frequency of these local oscillations cannot be equal to that of the whole circuit ACDE, which it has been stated was so easy to calculate, if the translations of Slaby's Paper I am relying on are correct. I believe that, notwithstanding the inductance CD, a considerable amount of energy must pass to earth through the earth wire, which acts as a leak uselessly dissipating energy which should be radiated into space in the form of ether waves. If these conclusions are correct, I am not at all clear as to what necessity there is for employing the earthed conductor ED and the inductance. It is not necessary for obtaining syntonic effects from transmitting stations placed at unequal distances from the receiver, as this can be obtained when using the primitive form of transmitter shown in Fig. 1; and Slaby has not yet described how to obtain different messages from transmitters situated at equal distances from the receivers, which is much more difficult in my experience; nor does it appear possible, with the method he describes, to transmit various messages at the same time from one sending wire as can be done with the system I have just explained. The distance obtained with the closed transmitting arrangement must be comparatively small.

As I have already stated, communication over a distance of 300km. is now being maintained with my system, but I am not aware of anything approaching even 100km. being achieved with the loop transmitter. It may be said that long distances of transmission are not necessarily an advantage, but I notice that the Navy wants long-distance apparatus supplied to it. I have also tried connections similar to Slaby's extension wire in the receiver, but I find that the real sifting out of waves is done in the oscillation transformer, although sometimes it may be desirable to increase the period of oscillation of the aerial conductor by adding inductance to it, or at other times to decrease its period by placing a suitable condenser in series with it. I trust it will not be thought that I wish in any way to minimise the importance of Slaby's work. I only wish to get at the facts and to draw a discussion on a very interesting subject.

Time does not permit me to refer to a great number of experiments upon which I am now engaged, or which have been carried out by others, but I hope on a future occasion to describe better results. I have come to the conclusion that the days of the non-tuned system are numbered. The ether about the English Channel has become, in consequence of great wireless activity, exceedingly lively, and a non-tuned receiver keeps picking up messages or parts of messages from various sources which very often render unreadable the message one is trying to receive. I am glad to say, however, that I am now prepared with syntonic apparatus suitable for commercial purposes. And, as my final word on the general subject for the present, let me say that those who are responsible for the recent development of wireless telegraphy into a practical science cannot fail to find great satisfaction in the reflection that, as already life has been saved that without this discovery would have been lost, so, in the future, apart from its manifold commercial possibilities, valuable as these are, humanity is likely to have before very long to recognise in telegraphy through space without connecting wires the most potent safeguard that has yet been devised to reduce the perils of the world's sea-going population.

DISCUSSION.

Dr. FLEMING, F.R.S., said that as he had been permitted to be a little behind the scenes, and had seen some of the apparatus before it was made public, he was able to entirely confirm Mr. Marconi's statements with regard to his experiments. A very great stride forward had been made in syntonic telegraphy. The subject was not a new one—in fact, a large number of patents had been taken out in connection with it, most of which, however, embodied more hope than experience. In spite of the fact that there were so many claims of priority in the matter, he had the strongest possible conviction that Mr. Marconi was the first person to actually achieve a true syntonic telegraphy with electric waves. He had done that in virtue of having followed out to their logical issue the fundamental scientific principles of the subject which he had so clearly grasped, one of which was the essential distinction between the radiative and the non-radiative circuit. Many inventors and patentees had professed to have obtained syntonic telegraphy with a simple open aerial insulated radiator of the Marconi type. Although it was possible to produce a kind of bastard syntonic telegraphy by that means, it was not possible to produce true syntonic telegraphy, because the aerial simply produced a sort of etheric impulse or explosion, and not a true train of waves. It was just as possible to produce true syntonic telegraphy by those means as it would be to cause one whip to crack by cracking another near to it. When a closed circuit was taken, which was a powerful absorber of electric energy and associated with a radiative circuit, a means was obtained for producing a true train of waves. If those two circuits were tuned together a great improvement was effected on anything previously accomplished. Mr. Marconi had not only constructed a receiver capable of receiving trains of waves, but also capable of not receiving those not adapted to it. No train of waves would act upon his syntonic receiver except those which had a particular period. An analogy might be found in a cork floating on water, which would be bobbed up and down by any wave, long or short, which went over it; but a heavy log of wood floating on the water and tethered to the bottom of the sea by a spiral spring would only be caused to bob up and down by waves having one particular period. The former corresponded to a simple coherer, and the latter to a syntonic receiver of the kind described in the Paper. He quite agreed with Mr. Marconi that the days of the non-syntonic telegraphy were numbered, because no one would chose a receiver capable of being affected by every vagrant wave when such an instrument as Mr. Marconi's latest form of receiver was available. Among the possibilities which lay in front of the invention was that it would be immediately possible to provide the Admiralty and the Post Office with instruments having an Admiralty or Post Office frequency, and to register frequency just as a telegraphic address was registered, so that no one else could use that particular frequency. He had had the privilege of riding on the motor car described by the reader of the Paper, and, when many miles from home, they were able to communicate with their hotel and order their lunches. In conclusion, he offered his warmest congratulations to Mr. Marconi on the immense strides he had made in the improvement of his initial invention.

Capt. KENNEDY, R.E., said he wished to explain, in common justice to Mr. Marconi, some of the points connected with the operation of the system in South Africa. A scheme was suddenly conceived and hastily executed of sending apparatus and assistants to instal the system at Durban. But instead of setting it up at that port, it was sent to the Front. No poles were available, and the attempts to substitute kites and balloons were unsuccessful. For want of labour and proper materials progress was slow, and eventually the work was stopped. On arriving in Natal, on the first opportunity, he handed the whole system over to Captain Percy Scott, who worked it most satisfactorily on board the ships at Durban up to the time he left South Africa. The operations in Cape Colony were entirely experimental, and would have succeeded had they been given a fair chance.

The CHAIRMAN (Prof. Ayrton) in proposing a vote of thanks to Mr. Marconi for his admirable Paper, said that, after listening to what wireless telegraphy had already done in saving life and ships, they realised why the reader of the Paper, although so young, had acquired fame; why he had won that more substantial reward which sometimes went with fame, but often did not, and also grasped why he had earned what should be dearer to him than fame or wealth—the gratitude of all peoples for having so courageously developed a new sense for the world. Although still far away, he thought they were gradually coming within thinkable distance of the realisation of a prophecy he ventured to make four years ago, of a time when, if a person wanted to call to a friend he knew not where, he would call in a loud, electro-magnetic voice, heard by him who had the electro-magnetic ear, silent to him who had it not. "Where are you?" he would say. A small reply would come, "I am at the bottom of a coal mine, or crossing the Andes, or in the middle of the Pacific." Or, perhaps, in spite of all the calling, no reply would come, and the person would then know his friend was dead. Let them think of what that meant, of the calling which went on every day from room to room of a house, and then think of that calling extending from pole to pole—not a noisy babble, but a call audible to him who wanted to hear and absolutely silent to him who did not; it was almost like dreamland and ghostland—not the ghostland of the heated imagination cultivated by the Psychical Society, but a real communication from a distance based on true physical laws. On seeing the young faces of so many present he was filled with green envy that they, and not he, might very likely live to see the fulfilment of his prophecy.

Mr. MARCONI, in reply, thanked Dr. Fleming for his kind remarks. To him he was also indebted for valuable advice on many subjects he did not understand, and in which Dr. Fleming's theoretical knowledge was of great value. In reference to Captain Kennedy's remarks, he wished to give an explanation. When the war broke out in South Africa he was asked whether he could send his apparatus out there. His associates, in reply, made two proposals: (1) To send apparatus for work at the Front, and (2) between shore stations and the transports at Durban. The proposal of using the apparatus at the Front was not accepted by the War Office at the time. The apparatus was sent out without poles because he was informed they would be found at Durban. On the arrival of his assistants in South Africa they pluckily volunteered to go to the Front, thinking the system might be worked with advantage to the English army; but, on reaching the front, poles could not be obtained by which to raise the wires. At that time, according to his old-fashioned system, this was absolutely necessary. Captain Baden-Powell came to the rescue with some well-designed kites, and signals were transmitted about 18 miles. Although the system was never used during operations in South Africa, it was not the fault of the system.

Review Of Reviews June 1901

THE LATEST TRIUMPHS OF ELECTRICAL INVENTION.

THE WORK OF MARCONI, TESLA, AND PUPIN.

BY PROFESSOR JOSEPH S. AMES.
(Of the Johns Hopkins University.)

WILLIAM MARCONI.

(This eminent electrical engineer was born in Italy in 1875; his father was an Italian and his mother an Englishwoman. Young Marconi studied at Leghorn under Professor Rosa, and at Bologna under Professor Righi. He experimented successfully with wireless telegraphy as early as 1896.)

PERHAPS the most important problem in science, with reference to daily life, is that of the rapid and accurate transmission of intelligence. Certainly, there is no question which at the present time is attracting so much attention from inventors and investigators; and at the Paris Exhibition of 1900 the most novel and suggestive scientific devices and methods shown were in this field. The daily press gives publicity to experiments, observations, and, unfortunately, vain prophecies on the subject, showing how much the world at large is interested in the matter. Within the past year, however, three names have been most prominent in the newspapers as having said something, or done something, which had important bearing on the question referred to. These are those of Marconi, Tesla, and Pupin; and each deserves serious consideration, although for different reasons. Marconi has made possible the practical application of wireless telegraphy; Tesla informs us that he is on the point of making great discoveries; Pupin has made a most wonderful improvement in long-distance telephony.

MARCONI AND WIRELESS TELEGRAPHY.

One of the most interesting chapters in the history of physical science is the story of what is nowadays called wireless telegraphy. By this name is meant the direct transmission of signals, without the help of connecting wires, between distant points, making use of disturbances which are produced in the luminiferous ether by electric oscillations, and which are detected by suitable means. The fact that there is in the universe a medium so subtle as to permeate the air, water, glass, and, in fact, all bodies, so that it may be regarded as a universal medium in which all the minute particles of ordinary matter are immersed, is familiar to every one at the present time. The existence of this ether was proved, at the beginning of the nineteenth century, through the labors of Thomas Young and Augustin Fresnel, who established the fact that all the phenomena of light are due to extremely short waves in a medium essentially different from air or any matter. Michael Faraday, about the middle of the century, was led by his experiments in electricity and magnetism to conclude that there must also be a medium, distinct from all forms of ordinary matter, by means of which electric and magnetic forces are felt. He conjectured that this electrical medium might be identical with the luminiferous ether of Fresnel; but it was reserved for Clerk Maxwell, the great professor of Cambridge, to prove this fact incontestably. He did so by showing, from mathematical considerations, that if the electric charges on any conductor could be made to oscillate, waves would be produced in the surrounding medium, which would spread outward

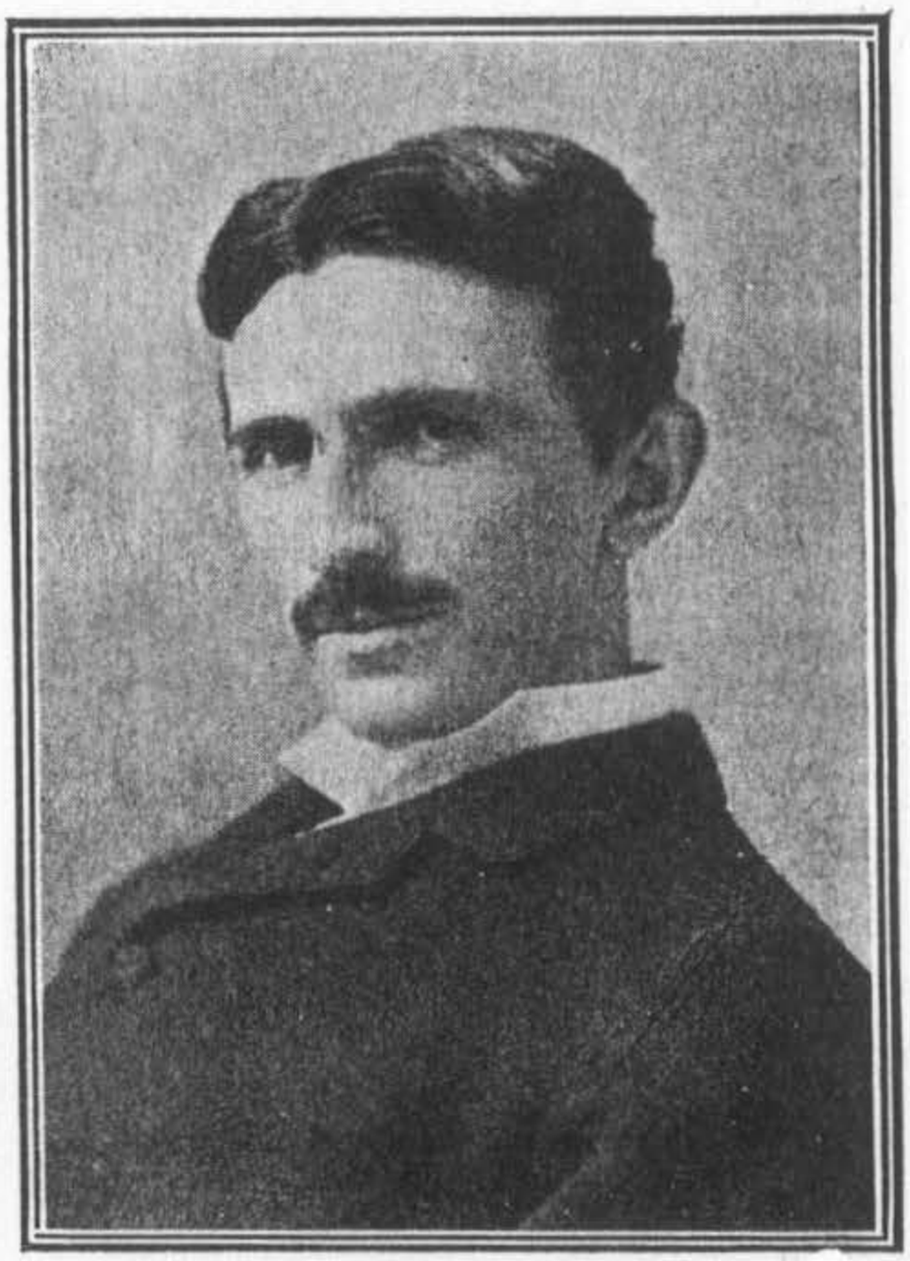
with the velocity of 186,000 miles per second, or, more exactly, 300,000 kilometers per second,—which is identically the same as the velocity of the waves in the luminiferous ether that produce the sensation of light, and are therefore ordinarily called light-waves. Maxwell showed, too, how it would be possible to calculate the wave-lengths of these waves produced by electric oscillations. But whereas those ether-waves which produce light when they reach the eye are extremely small, being on the average about one fifty-thousandth of an inch in length, those due to electric disturbances are much longer, varying from one-tenth of an inch to many miles.

No one, however, for many years devised any instrument for the detection of these long waves, or, in fact, elaborated any method for their regular production and observation. This was finally done, in 1887, by the talented young physicist, Heinrich Hertz, professor of physics at Carlsruhe, one of Helmholtz' greatest pupils. Hertz produced his electric oscillations by means of an induction-coil, charging with opposite kinds of electricity two conducting metal plates which had two projecting knobs coming close together. The action is as follows: When the charges become sufficiently great, a spark passes between the knobs; and while the spark lasts—a very minute fraction of a second—there are surgings of the electric charges backward and forward from one plate to the other through the spark. Then the plates become charged again, are discharged, and again there are those electrical surgings to and fro. As a result of these oscillations *on the conductors*, disturbances are produced in the surrounding ether, which spread outward in all directions, just as, when a stone is dropped into a pond of water, waves are seen advancing outward in ever-widening circles. It may be noted here, once for all, that the disturbances in the ether do not come from the spark, which is so conspicuous to our senses of sight and hearing, but are due to the surgings on the conductors. For this reason, it is self-evident that the length of the waves must vary with the size of the conductors; the longer the conductor, the longer the waves. It is obvious, also, that long waves are less affected by obstacles than are short ones,—they can pass around them; and it may be shown that the longer the waves are, the farther they will go before fading away and becoming too weak to be observed.

Hertz discovered that a simple means of detecting these waves was to bend a wire into the form of a circle, so that the two ends nearly, but not quite, met; for, if this "receiver" is suitably turned, there will be minute sparks across the gap as the waves pass. Using the oscillator and receiver just described, Hertz showed that the waves produced by the electric oscillations traveled with the velocity predicted by Maxwell, and that they obeyed all the ordinary laws of reflection and refraction which are associated with the phenomena of light. Hertz showed how these disturbances in the ether could be noticed at considerable distances,—many yards; and other investigators, like Lodge, Trouton, and Rutherford, who repeated and extended Hertz' experiments, proved that these effects could be observed at a distance of several miles, through intervening walls and buildings. One of the first to be interested in Hertz' work was Professor Righi, of the University of Bologna; and one of his pupils, Marconi, saw in these new discoveries the possibility of using the methods for the transmission of messages. In the meantime, too, a much more sensitive receiving instrument had been perfected by professors Onesti and Branly independently—the "coherer." This consists of a glass tube containing minute loose metallic filings, into each end of which enters a metal wire joined to a source of electric current, such as a voltaic cell. The filings do not in a normal state make electric contact, and so no current flows; but if long waves in the ether pass by, they produce electric oscillations in the conductors projecting out of the tube; and, as a consequence, the filings in the tube cohere and make connection, so that an electric current is now produced, and can be detected by any suitable means. A slight tap on the tube will cause the filings to decohere. Marconi studied the conditions under which a coherer was most sensitive, and those under which an oscillator would send out the most intense waves, and the ones best adapted for practical use over the surface of the earth. He then devised a simple method for using a "dot-and-dash" system of signals, depending upon having a short or a long series of electric discharges. Marconi deserves a great deal of credit for his perseverance in interesting the governments of Europe and this country in his enterprise, and for overcoming the practical troubles which arose when it was attempted to transmit the signals in the ether to such great distances as fifty or a hundred miles.

It is not possible, however, to increase the intensity of the electric oscillations indefinitely, and the limits of sensitiveness of the coherer have probably been reached. It must be borne in mind, too, that the waves in the ether produced by the electrical surgings travel outward in straight lines, except as modified by reflection; and this last has little effect when the oscillator is a vertical conductor, as it is in all commercial sets of apparatus. The presence of ordinary mat-

ter, such as a building or a hill, affects the progress of these waves only slightly, provided it is not a good conductor for electricity. If such is the case, however, the energy of the waves will be seriously reduced, if the body is of sufficient size. Thus, when an attempt is made to send ether-waves from one point to another distant one hidden from it by a mass of salt water owing to the curvature of the earth, there is not the least reason for believing that it will succeed. Messages are easily sent across short distances on the ocean; but this is due to the fact that the ether-waves used are so long that, unless the sending and receiving points are very far apart, portions of the waves, although passing in straight lines, do not traverse the water itself, but go above it.



There have been, up to the present, two difficulties which have stood in the way of the more universal application of "wireless telegraphy;" one was the impossibility of locating accurately the direction from which a message came, the other was the fact that if several messages were being sent at one time their effects would overlap, and the signals received at any station would be a confused mixture. This first difficulty can be obviated to a certain extent by using suitable mirrors, provided the ether-waves are not too long; and the second has been almost completely removed by the recent work of Professor Slaby, of Berlin, using a method of resonance long since proposed by Professor Pupin, of Columbia College, New York. Slaby has perfected his apparatus to such a degree that he can make an oscillator which will produce waves in the ether of a definite period of vibration, and a receiver which will respond to waves of a definite period, but to no others; so that however many waves, of whatever periods, are passing over a receiver, it will pay no heed to them unless they are of the proper period. It thus becomes possible to transmit messages free from the disturbing influence of other ether-waves produced by vibrations.

Naturally, the field of usefulness of wireless telegraphy is limited. It can never compete with the long-distance telephone or the rapid telegraph systems; but for maintaining communication between moving vessels, vessels and the land, and across channels, where cables are not safe, it offers by far the most satisfactory solution of the obvious difficulties. It should be noted that some of the most important and successful modifications in wireless telegraphy methods have been made in this country under the direction of the officers of the United States Signal Service.

The history of wireless telegraphy would not be complete without some mention of Joseph Henry, America's greatest scientist, for it was he who first, in 1842, discovered the oscillatory character of certain electric discharges, and who showed that these oscillations produced disturbances which could by suitable receivers be detected at distances of many rods and through intervening buildings. He even arranged an apparatus on this principle to respond to the lightning discharges of distant storms. The great genius of Henry was never more apparent than in his investigation of electrical discharges and their oscillatory nature. It is a lasting testimony to the ignorance among Americans of their own great men that the name of Joseph Henry is not included in the fifty selected for the "Hall of Fame" of the nation.

TESLA.

It is extremely difficult to take Mr. Nicola Tesla seriously, and still more so to understand the credulity of the people to whom the daily paper is an organ of science. Mr. Tesla has done so much good scientific work, and has been so skillful in the preparation of theatrical lecture-

NIKOLA TESLA.

(Although of Servian birth and education, Nikola Tesla has lived for many years in the United States and is well known as an electrician, especially in connection with the problem of power transmission at Niagara Falls.)

experiments, that it is greatly to be wondered at that he does not again make a definite invention or perfect some apparatus or method. The Tesla motor, so called, and the electrical machines which

are modifications of it, are known to the world, and so is the "Tesla coil," which is a simple improvement of one of Henry's instruments; but as yet no discovery bears his name, and all the wonderful experiments with which he delights audiences at home and abroad are extensions of familiar ones, shown on many lecture-tables by the ordinary teacher of physics. With such knowledge and such skill, it is incomprehensible why the articles bearing his name should appear in magazines and daily papers. It may be that Mr. Tesla has a knowledge of experiments not known to the world; but if he has, he owes it to the world and to himself to publish the *facts*,—what he knows, not what he thinks will make interesting reading for those who are ignorant of physical science but are looking to science and scientists for extension of man's knowledge of the truth hidden in nature.

PROFESSOR PUPIN'S INVENTION.

In the recent invention by Professor Pupin, of Columbia University, of a new principle in the transmission of electrical waves along metallic wires there is much more of interest than at first sight appears. Professor Pupin is a trained physicist and mathematician, and has been interested for some time in the study of the propagation of electrical waves along conducting wires, using both theoretical and practical means to help him in his work. He investigated the subject mathematically, and saw from his equations that if he were to modify the conducting wire in an entirely new but perfectly simple manner, many of the difficulties in the way of the transmission of the waves would be removed. He therefore constructed in his laboratory the modified "line," so as to represent an improved telegraph or telephone wire, tested its action, and found that it was exactly as he had known from the start it would be. So important to practical commercial companies was the invention, that Professor Pupin has been able to dispose of his patent-rights for a sum which to the ordinary college professor seems beyond the dreams of avarice. The most striking feature in this invention, as in so many recent ones, is the fact that it could never, under any imaginable conditions, have been made by a so-called "practical man." It required, first of all, the genius of an inventor; and next, and to a no less important degree, the training in mathematics and physics which only the greatest universities in the world can give. The demand in modern technical schools should be, not for less theoretical instruction in abstract subjects, but for more. Failing this, the engineer of any kind, civil, mechanical, or electrical, is hopelessly limited in his power for invention or for the improvement of existing conditions.

It may be easier to understand the difficulties in the application of electrical waves which are overcome by Professor Pupin's invention, and the vast changes which it makes possible, if one consider for a moment a more familiar illustration of waves. If a long, thin cord, or rope, lies along a floor, one end being fastened and the other held in the hand, mechanical waves may be sent along the rope by moving the hand rapidly and regularly up and down. The more rapid the vibrations of the hand, the shorter will be the wave-length—that is, the distance from "crest" to crest. It is seen at once that the waves do not advance very far; they "die down," or become "attenuated," owing to the fact that the energy due to the work done by the hand in moving the end to and fro is all lost in the rope. It may be seen, too, by trying the experiment, that long waves are less affected than short ones, and so are propagated along the rope to a greater distance than are the short ones, before they die away entirely. It is thus easily understood that if the hand is moved up and down in a most irregular manner, yet repeating

PROF. MICHAEL I. PUPIN.

(Dr. Pupin was born in Austria in 1858. He came to America at the age of sixteen, and was graduated from Columbia in 1883. Further facts in Dr. Pupin's career are given on page 344 of the REVIEW for March, 1901.)

its motion at regular intervals, there will be waves of different lengths sent along the rope; but that as the shortest waves die down, leaving the longer ones, the character of the disturbance seen moving along the rope will change. This is called "distortion."

The attenuation of the waves is greatly diminished, and is made nearly the same for both long and short waves, if a heavier cord is taken; for instance, if the first one is like the cotton rope used to hang window-weights and the other is a flexible metal cable. (It is true that in this change the actual magnitude of the disturbance decreases; but the work done at one end of the rope will now be manifest farther along toward the other end.) Both attenuation and distortion are thus decreased. If it be not desired to use a heavy cord, the first one may be so modified as to have all the advantages of the former. This is done by attaching small, heavy pieces of lead or other metal to the rope at regular intervals apart; and the "weighted" rope will now behave like a heavy one for waves of all wave-lengths much greater than the distance from one load to another. Professor Pupin showed that the proper arrangement was to have not less than fifteen or sixteen "loads" in the distance of one wave-length. Thus, a heavy rope with its weight distributed in beads keeps all its essential properties unaltered.

For any one feature of the propagation of mechanical waves along a rope there is an exact analogy in the phenomena of electricity. Electrical waves in a conducting wire are produced in many ways,—each time one speaks into a telephone, waves are produced along the wire; whenever a telegraph-key is depressed, there is a wave. There are the same difficulties to overcome in the application of electrical waves as those just described in the illustrations of mechanical ones,—attenuation and distortion. For instance, in order to secure the transmission of a signal over a long submarine cable, it is necessary to have very long waves, and this requires a slow rate of sending messages; more rapid vibrations would die away before reaching the farther end. Again, when one speaks into a telephone, there are produced waves of many lengths, depending upon the varying notes of the voice; these waves die down at different rates, and the sound heard at the hearing instrument is essentially different from that spoken. Low sounds carry farther than high ones, and every one knows from experience how difficult it is to hear certain shrill sounds in a telephone. In "long-distance" lines, the only remedy in the past has been to use larger copper wires, and to avoid as far as possible all disturbing influences. Thus, as a rule, long-distance wires avoid towns or cities where local electric circuits might produce waves of their own. Pupin has proposed absolutely different modifications. When the rope in the mechanical experiment was made heavier, its "inertia"—its opposition to the disturbing action of the waves—was increased; now what corresponds to this with the electrical waves along a wire is to wind it in the form of a coil or helix! This was one of Joseph Henry's great discoveries, also. If a wire is wound like thread on a spool, it offers opposition to the production of an electrical wave exactly analogous to that offered by the heavy rope to the mechanical wave. Similarly, if the wire runs straight for a short distance, is then coiled up, then goes straight, is again coiled up, etc., it corresponds perfectly to the loaded rope. Electrical waves can be sent along it to great distances with comparatively no attenuation and distortion. Pupin's project is, then, in short, to modify a telephone-wire by cutting it at definite points—every few posts—and by joining the cut ends with those of a small coil of wire wound on a spool. He has worked out carefully the exact size of the coils to be used under different conditions, and the proper distance apart to insert them. For telephone purposes, the coils occupy a space of a cube scarcely five inches on an edge, and are about one mile apart; while for ocean cables, the coils are so small that they can be included in the sheath, lying close to the cable-wire itself, but they must be as near together as one-sixth of a mile.

The advantages of this system of Pupin's are enormous, especially from a commercial standpoint. The rate of signaling over submarine cables will be increased so as to rival that of land lines; and there is no reason to doubt but what telephonic communication will be possible over them. This statement should not be regarded as a prophecy, but as an interpretation in the language of commercial life of experiments in the laboratory.

On land, the saving of copper in the construction of long-distance lines will be most important. Communication can be maintained over much greater distances than is now possible. All disturbances from local induction and from lightning are absolutely avoided. The rapidity of the oscillations in a lightning-flash are so great that if a wire is struck the waves produced will be so short that when they reach one of the coils they will not be able to pass it, but will be reflected, and will thus be frittered away by being reflected to and fro along a small section of the wire. In every way, therefore, the invention of Pupin is one of the most noteworthy events in the modern application of science.

Nitrogen and Tesla Currents.—KAUFFMANN and HELL.—An account of an experiment in which nitrogen was exposed to the influence of Tesla currents. The nitrogen is contained in a wide glass tube, in which there is a narrow tube filled with mercury connected to one pole of a Tesla coil, while the other pole is connected to an external tin coating on the wider glass tube. On working the Tesla coil, a blue fluted light appears in the wide tube, accompanied by a green fluorescence of the glass walls. The green fluorescence appears to be generated wherever the blue rays impinge upon the glass, just as if these were cathode rays.—*Phys. Zeit.,* May 11; abstracted in Lond. *Elec.,* May 24.

The New York Tribune August 7, 1901

TESLA READY FOR BUSINESS.

HE HAS BOUGHT THE LAND FOR HIS WIRELESS TELEGRAPHY STATION AND LET THE CONTRACTS FOR THE BUILDINGS.

Nikola Tesla's plans for a transatlantic wireless telegraphic system are now so well in hand that he has bought a site for the station on the Long Island shore, and has agents looking for a suitable place for a station on the British coast. The station in this country will be at Wardenclyffe, on the Sound, nine miles east of Port Jefferson. Mr. Tesla has purchased two hundred acres of land in that vicinity, and closed contracts yesterday for the necessary buildings.

Five or six buildings will be erected on different parts of the tract, the largest of which is to be one hundred feet square and several stories high. It will contain, Mr. Tesla says, one of the most complete electrical plants that can be purchased. Three hundred and fifty horsepower will be developed, and the total cost will be nearly $150,000. The other buildings will be used for the electrical experiments with which Mr. Tesla is now engaged, including a system of lighting by diffused light. He will probably give up his present laboratory, at No. 46 East Houston-st., and make his headquarters at Wardenclyffe.

Mr. Tesla has been working for several years with his system of wireless telegraphy, and believes that he has advanced far enough to warrant a change from the experimental to the commercial stage. He says it will not be long before he will be transmitting commercial messages between Wardenclyffe and Europe without the use of wires or cables.

When seen at the Waldorf-Astoria Hotel last night Mr. Tesla said:

"I would have been sending messages across the ocean without the use of wires by this time if the public were not so hard to convince that it could be done. It takes time to assure people of the truth of new discoveries. It was six or eight years before people believed in my system of transmitting electric power. Now it is used everywhere. I cannot tell you just how far I have advanced in the perfection of my system of telegraphy, but I hope soon to be able to show most convincing results."

Important if True.

Press dispatches state that Nikola Tesla has received word that the apparatus he has devised for the transmission of electric energy is completed. Three stations have been arranged for on the other side of the Atlantic, it is said—one in Portugal, one in France and one in Germany. Mr. Tesla expects that by the end of September all the mechanism for the transatlantic service will be in position.

In our issue of January 18th we described Prof. Slaby's "tuned" system of wireless telegraphy, indicating the theoretical principles on which it is based. More recently Prof. Slaby has delivered another lecture on his method, and we publish an extract of this in another column, with diagrams of the connections employed—and employed with complete success. The conclusion of his article, with its allusion to the present work of Mr. Tesla, comes as a considerable surprise. No one will deny that Mr. Tesla possesses genius—his valuable work in connection with polyphase methods alone demonstrates this. But from the soil of his genius have sprung up two varieties of dangerous weeds—a craving for notoriety and dreams of ultimate possibilities, and these have grown so thickly that it requires a skilful gardener indeed to discover the fruit. If Prof. Slaby has patience enough to do this it redounds to his credit; for otherwise if the illustration in the professor's lecture is a true picture of the condition of Mr. Tesla's laboratory, it seems probable that the ultimate result of the séances held by the wizard of the Rocky Mountains may be merely another wildly imaginative article such as that written by Mr. Tesla in the *Century Magazine* a year ago, or a description of an elaborate attempt to inspire an appreciative personal notice in the sensational press of the Martians.

THE LATEST PROGRESS IN SPARK TELEGRAPHY.*

BY PROF. A. SLABY.

The latest form of connections of the wireless telegraph apparatus made by the Allgemeine Elektricitäts Gesellschaft are as follows. The transmitter (Fig. 1) consists of wire fastened to the flagstaff of

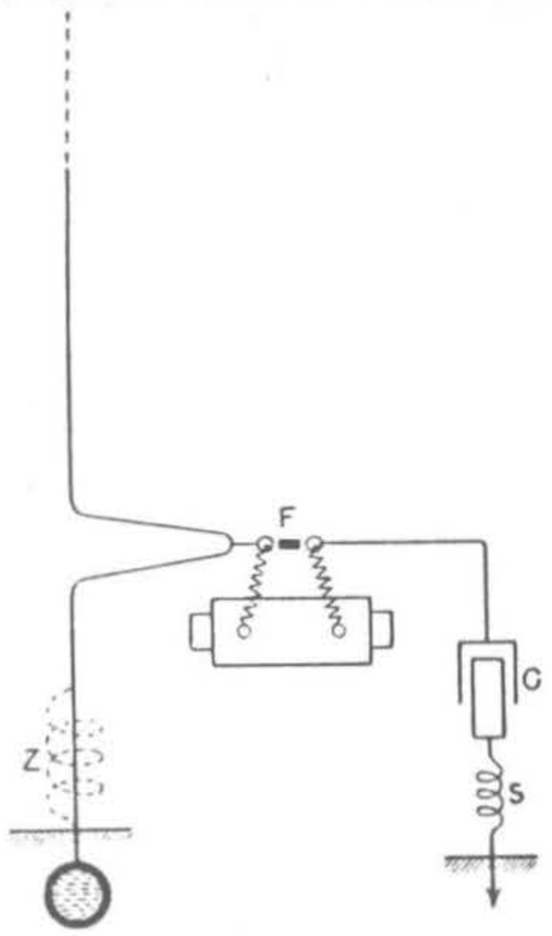

FIG. 1.

the building, which is led to earth and connected with the water main. A loop in this wire is led through the window into the room, and is connected to an induction coil, F, the other pole of whose secondary winding is connected to earth through a tuned condenser, C. If we wish to telegraph with a greater wave-length, it is only necessary to connect an additional coil, Z, in the earth wire, as shown by the dotted line. It corresponds to a certain equivalent length of wire by which we increase the quarter wave-length, and a whole set of such coils can be employed. In each case, however, it is necessary to tune the oscillation produced in the circuit closed by the earth connection to the oscillation of the wire, in order to obtain the greatest effect. This is done in the simplest manner by adjusting an adjustable self-induction, S, or the condenser C, which bear particular marks for this purpose.

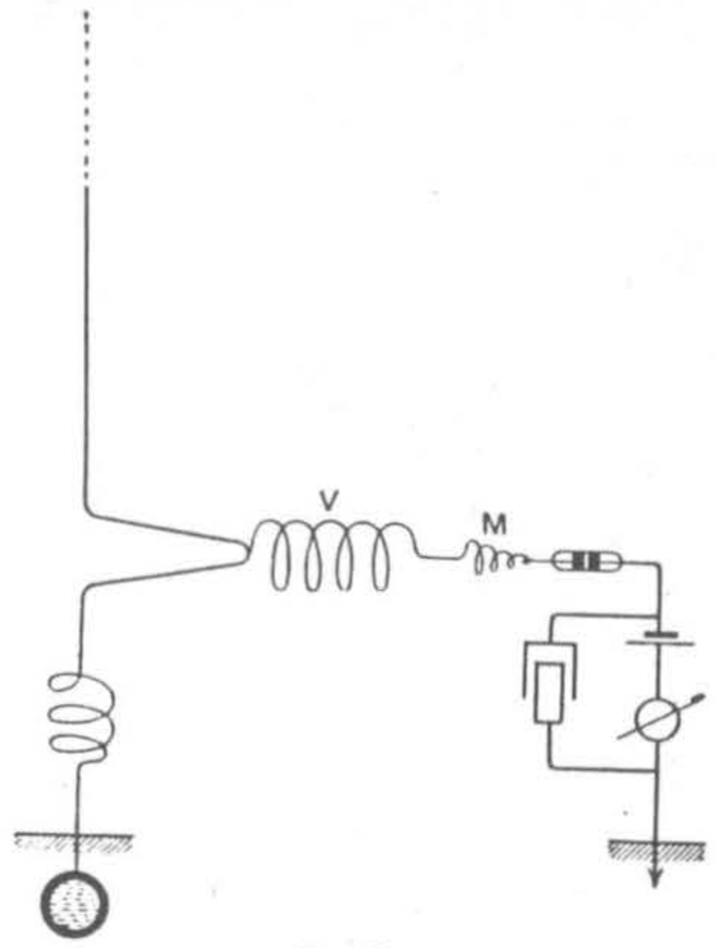

FIG. 2.

A similar wire serves as the receiver (Fig. 2), to which, also, an extension wire in the form of an equivalent coil, V, is connected by means of the loop. The pressure is at its maximum at the end of the latter, and is strengthened by a tuned intensifying coil M, which

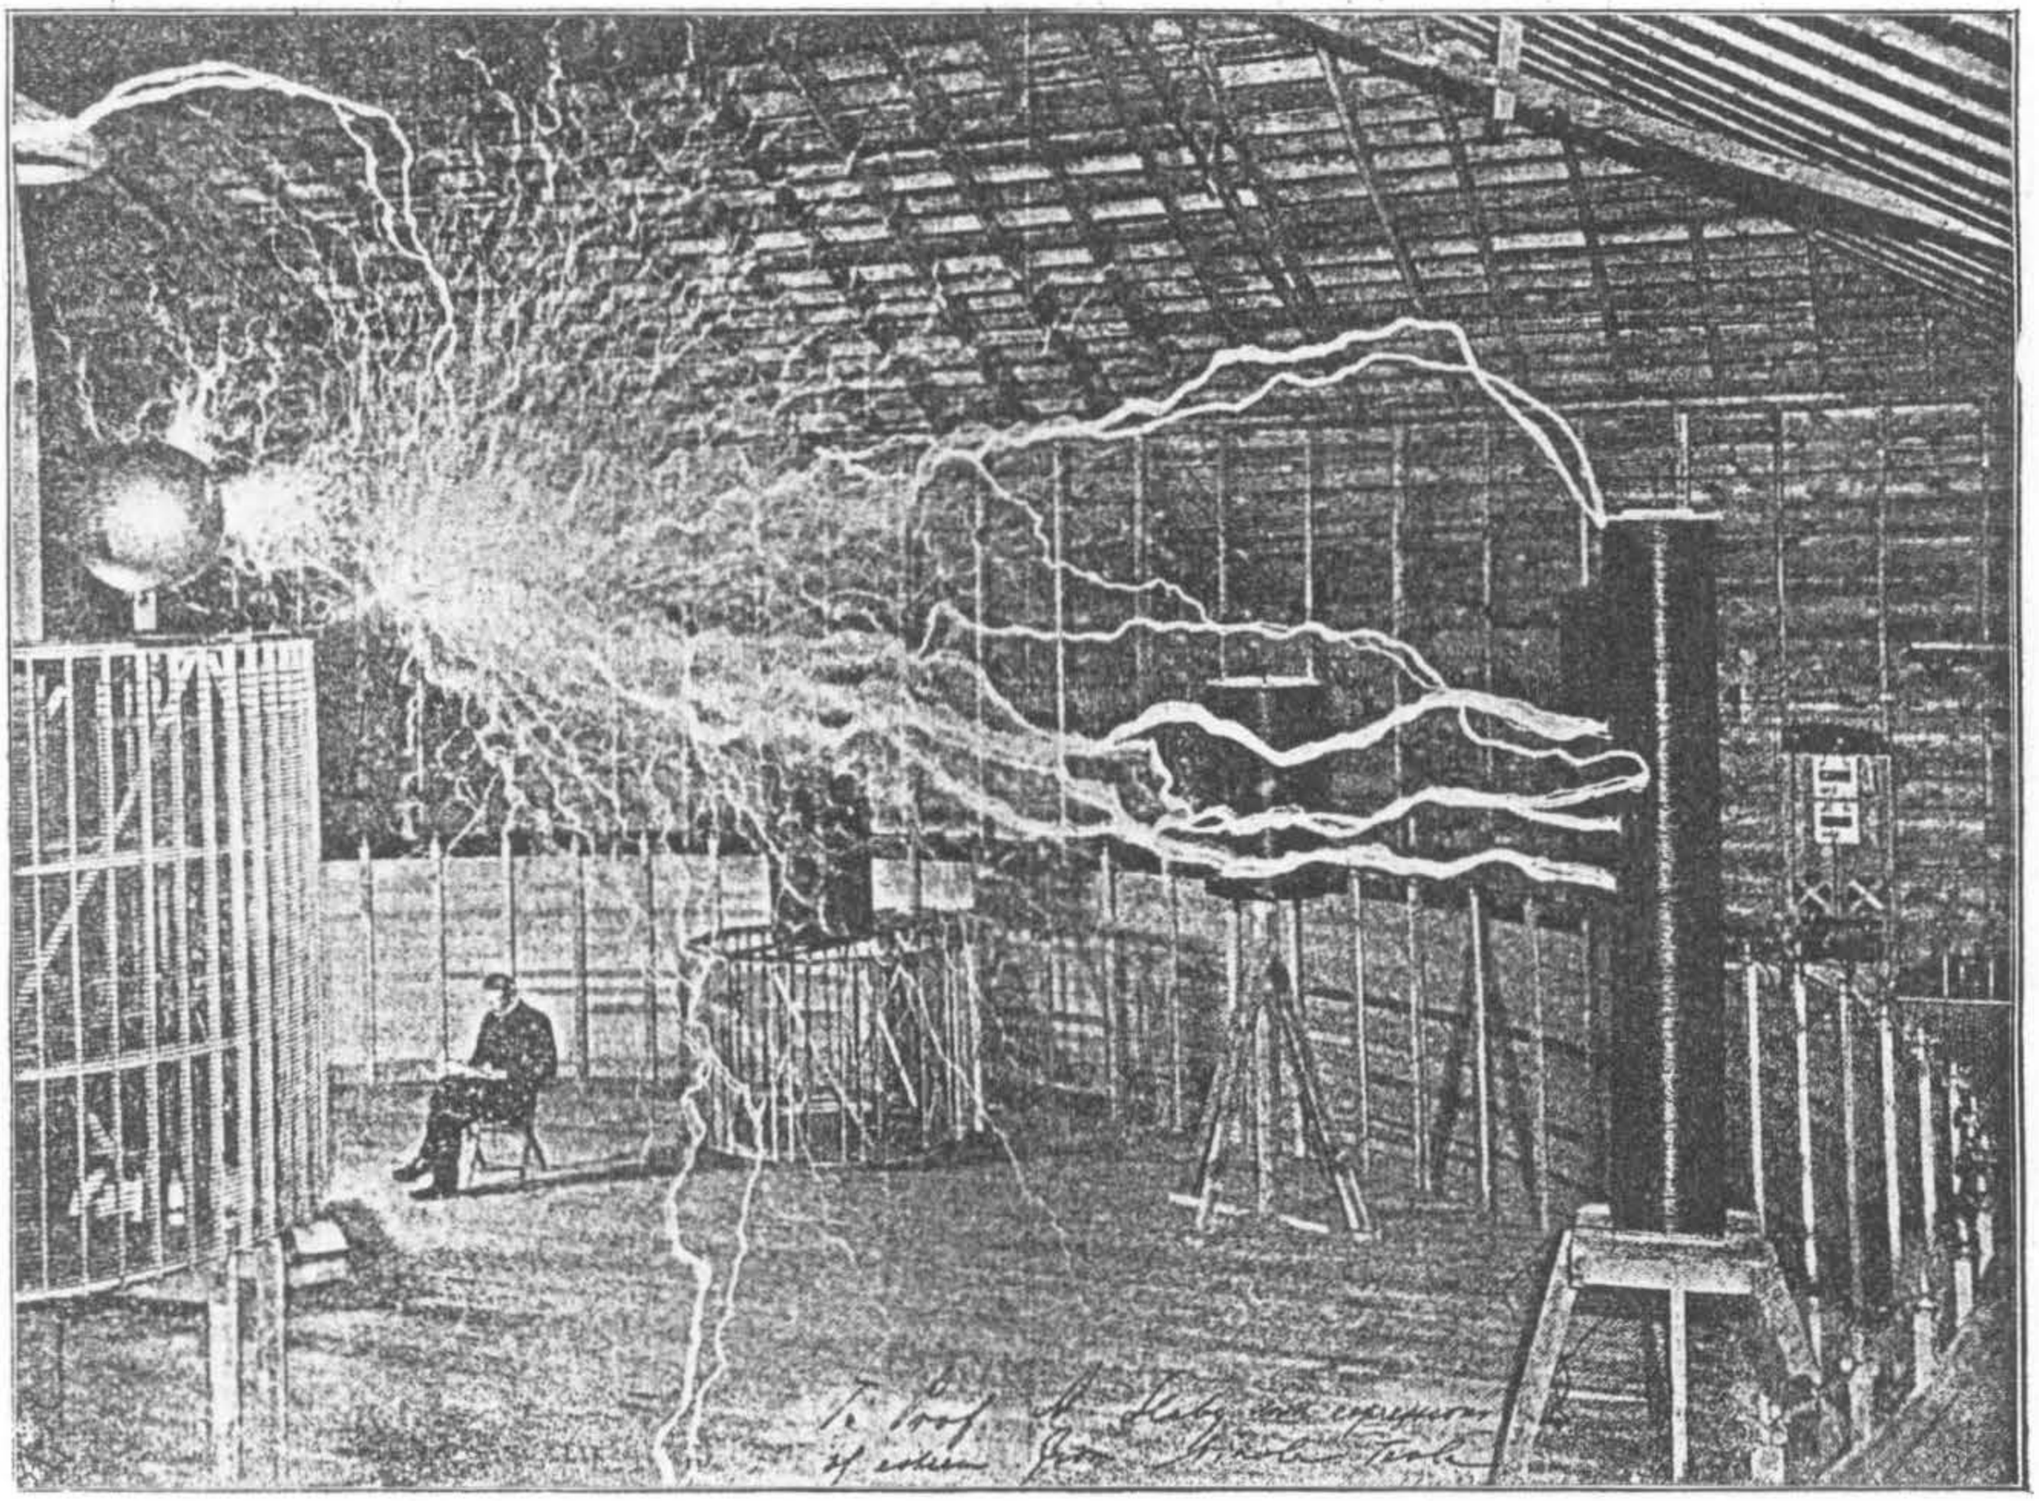

FIG. 3.

* Extract from a lecture delivered at the forty-second general meeting of the Verein Deutscher Ingénieure, at Kiel.

is connected directly to the coherer. It is also possible to replace the action of the two coils by a single coil with corresponding winding. The earth connection of the coherer contains the dry cell and the relay, which are bridged by a condenser in order not to disturb the oscillations. The Allgemeine Elektrictäts Gesellschaft guarantees with this arrangement a tuning to the required wave-length within certain limits, and a clear deciphering of signals at distances of 100km. on the sea with masts 50 metres high.

Spark telegraphy has now left the condition of tentative experiment and has developed into actual engineering to accomplish a definite object, and the active forces of the industry will soon do what is needful to extend its sphere of applicability. It will, in the first instance, become an indispensable means of communication on the coast and on the open sea, where the life and property of mankind is most endangered, and I do not think it will be long before every large ship will be equipped with this simple and useful apparatus. But spark telegraphy will also, in the future, replace cable in many cases for submarine communication, although in this respect we must not place our hopes too high. We can almost now see the limits, putting aside extravagant plans, as, for instance, elevating a wire 1,000 metres by means of balloons, which may be possible in an individual experiment, but is worthless in practice for reliable continuous working. We can scarcely expect a transmission of signals of more than a few hundred kilometres even with more perfect development of the means at present at hand.

The way open for further progress is also clear. The distance of transmission depends essentially on three things, the length of the parallel wires, the frequency of the pulsations, and the mean value of the current employed. The first two can hardly be increased, and also extending the length of the wire requires longer wave-lengths and consequently slower frequency; and, therefore, quite a new means would have to be found to make the wave-length independent of the length of wire employed. An increase of the induced current only remains therefore. This depends on two quantities, the capacity or receptive power of the wire, and the actual pressure of the spark. The higher we take the wire the smaller will be the capacity of the parts distant from the earth, and the longer it is the harder it will be to secure it in stormy weather. Thus I hope to have shown that the future of spark telegraphy lies exclusively in the direction of producing higher electrical pressures. What we have used in this direction hitherto is very modest if we compare it with what has been shown to only a few of the initiated, far from here on the other side of the ocean, on the high Rocky Mountains at the sources of the Colorado River, by an investigator who has shut himself off from the world—Nikola Tesla. I cannot report on it as an eye witness, but can only form my opinion from some photographs which he has most kindly sent me a few days ago. Here (Fig. 3) one sees him in his lonely house surrounded by artificially-produced spark discharges, which throw into the shade all that our most daring fancy has dreamt of. May his theoretical knowledge and his eminent technical ability soon be placed at the practical service of spark telegraphy.

Tesla Patents.

As noted in our issue of last week, two decisions have lately been handed down sustaining the Tesla patents, one from the United States Circuit Court of the Southern District of New York, and another from the United States Circuit Court of Appeals for the Second Circuit.

The first-mentioned decision was by Judge Lacombe. The defendant's device is an alternating-current wattmeter, and it was contended by the complainant that the circuit to which the meter is connected is divided so that part passes through a fine wire coil and another part through a coarse wire coil, and that as a consequence there is a difference in phase between such circuits. The complainant contended that this arrangement is an infringement of two Tesla split-phase patents, both bearing date of Dec. 26, 1893.

The defendant contended that the device does not constitute an infringement for two reasons, that the patents at issue cover motors only, while the device in suit is a meter. In the opinion of the court, this is a mere verbal distinction without apparent merit. The patents contemplate the production of power, though they are wholly silent as to the amount of power. The meter exerts power, its disk rotates against the action of a permanent magnet and turns a spindle which operates the registering devices. Second, the defendant contended that the meter does not operate by virtue of the so-called "Tesla rotating field" of the polyphase patents. The court considers that the preponderance of evidence indicates that in the motor in suit there are independent energizing circuits; that alternating-current from a supply circuit is passed through both, and that by a variation or modification of the relative resistance or self-induction of these energizing circuits they are put into different phase; and that the revolvable disk becomes effectively operative because such arrangement exerts its influence through the development of a rotating field, which is characteristic of Tesla methods.

The conclusion of the court is that the motor involved an infringement of the claims of both the Tesla patents above mentioned.

The second decision is by Judge Shipman, and was on an appeal from the Circuit Court of the District of Connecticut in the suit of the Westinghouse Electric Manufacturing Company against the New England Granite Company. The Circuit Court opinion of Judge Townsend was printed in our issue of Sept. 8, 1900.

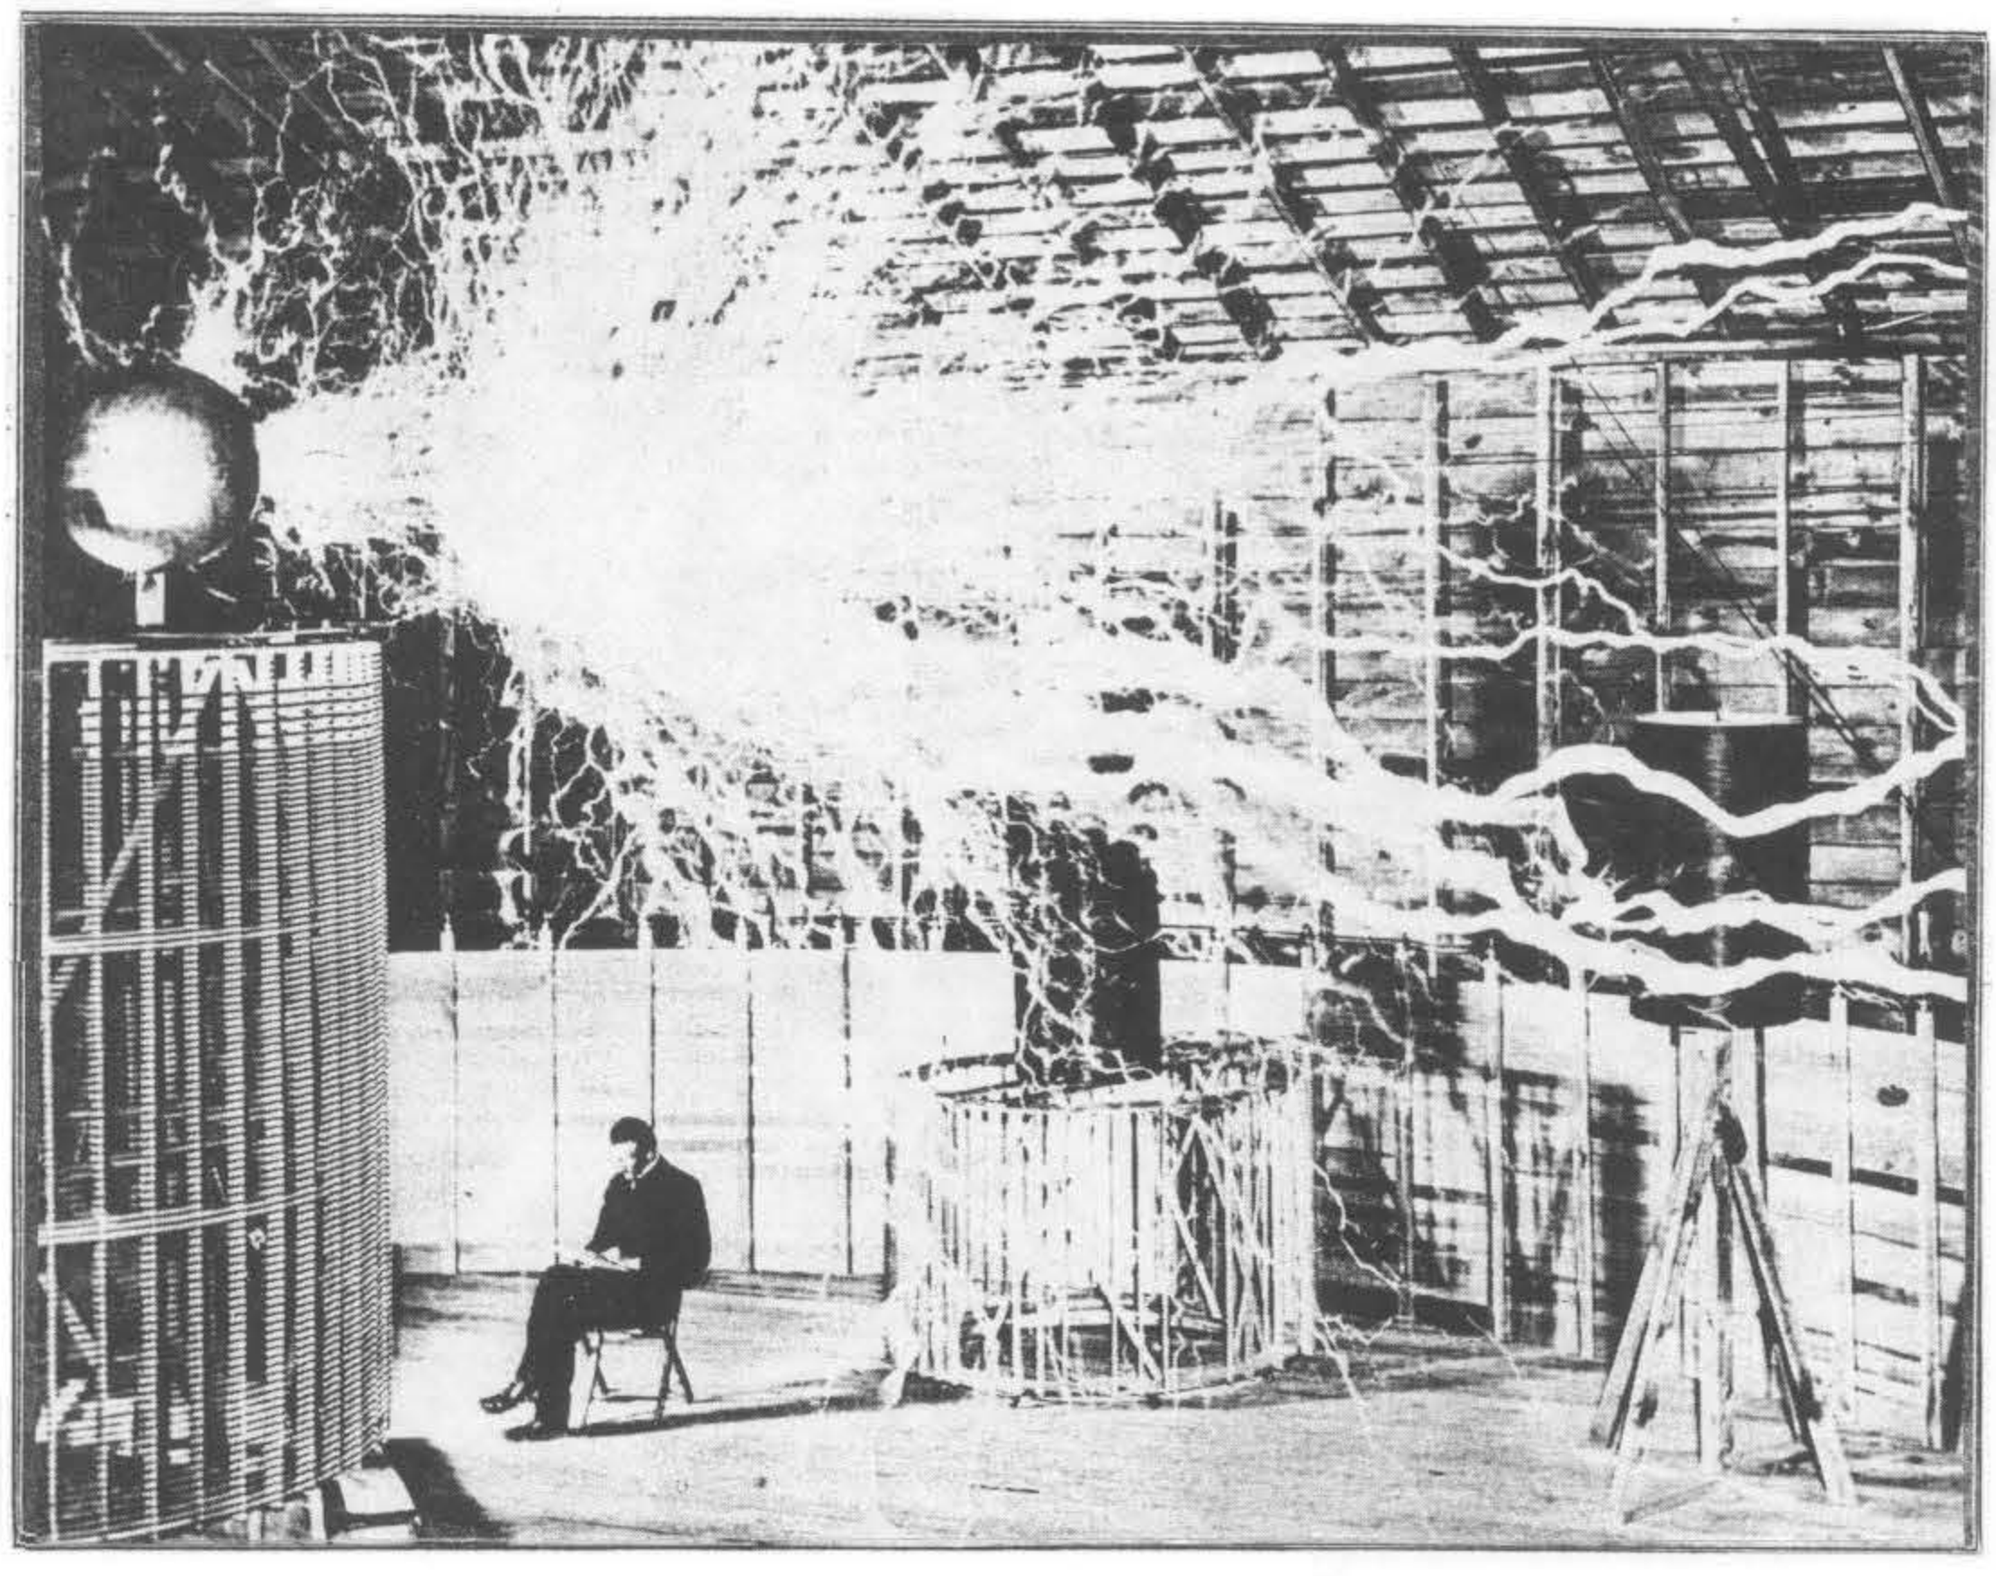
The opinion of Judge Shipman is lengthy, and quotes largely from that of Judge Townsend, which it sustains. Taking up the main points of the defense, it is noted that Bailey said that the object of his experiments was to cause a disk to rotate by an intermittent rotation of the field, effected by electromagnets, and this statement is sufficient to show that he neither thought of nor unconsciously aided in solving the problem of transmission of power by electric currents of any kind. Bailey, in his experiments with reversed currents did not attempt to produce, as Tesla did, a continuously rotating field. Reverse currents and alternating currents, though they may be equivalents for some purposes, are not equivalents for transmission of power over a distance. Reverse currents cannot practically be used for that purpose.

Taking up the Bradley defense, it is stated that Bradley's alleged invention was a dynamo "which would generate an alternating or a continuous current as desired." He described two currents obtained from the same machine, and says that they can be employed for any purpose for which alternating currents are applicable, and they may be used separately, one being employed to feed one circuit and the other to feed another circuit, but he apparently did not in his application understand any benefit resulting from the transmission of two currents of different phase.

Judge Townsend is quoted to the effect that Bradley's application is limited in scope, ambiguous and indefinite. It fails to show that he had any conception of the Tesla idea of "the utilization of the motor for the purpose of progressively shifting the magnetic poles of a plurality of alternating-currents by circuits which preserve the independence and differing time relation of the other phases." Even if the idea had been first conceived by Bradley it was not sufficiently described to disclose a principle or method of operation. Bradley does not anticipate or limit this principle, Tesla being the first to reduce it to practice.

As to the Marcel Deprez defense, what Deprez did was to mathematically demonstrate that the polar line of an annular magnet may be shifted the entire circumference of the ring by two magnetizing forces properly related; he showed how a resultant magnetic field could be produced, but he did not describe or suggest apparatus for power. His currents were not the alternating currents of Tesla. Giving the Deprez theorem all the value to which it is entitled, its application by Tesla to the production of a new, original and most beneficial practical result by new and described means and the use of polyphase alternating currents; in brief, by the polyphase system —the apparatus of Tesla nevertheless was an invention of a very high order.

Referring to the Siemens patent of August, 1878, it is stated that the drawings showed direct-current machines and those capable of being both direct and alternating. The part of the specifications upon which the defendants lay stress is as follows: "It is to be understood as stated above that with suitable modifications these apparatus are generally applicable also as rotary transmitting machines, the rotary parts being caused to revolve and give out mechanical power when electricity is applied to them, and thus one of these machines may be driven by any suitable motive power so as to generate electricity, and this electricity may be conducted to a similar machine at a distance, causing it to work and to give out a portion of the power applied in the first instance." The opinion states that no modifications are described, and there is no suggestion that the patentee thought of such connections between the generator and motor, each of two phases, as to preserve the phases of the two and the difference of phase, and that currents should act independently and regularly succeed each other and thereby keep the armature constantly rotated. The hints in the patent respecting the modifications by which the apparatus could be made to give out mechanical power were valueless, as no modifications are described, the kind of apparatus to be modified is uncertain and independence of phase was not in contemplation by the patentee.



As to the claim that the reversibility of the Siemens or Bradley apparatus followed from a principle universally recognized as to the reversibility of electric machines, it is stated that the reversible principle, while true in regard to direct-current machines, was only a matter of theory and not of practice in regard to alternating-current motors for power purposes. Declarations that such machines could be so reversed so as to furnish power were merely theoretical and gave no information to the inventor of the method by which reversibility was to be made useful to accomplish any result.

As to the point that infringement of the patents in suit is limited to synchronous motors and thereby not infringed by the defendant's induction motor, the opinion says that assuming the patents did describe synchronous motors only, their claims did not make and did not intend to make synchronism a part of either patent, but were for the broadly described invention of "a novel system of electric distribution and transmission of power by means of alternating currents."

Tesla's High-potential Work.

Professor A. Slaby recently delivered a lecture on "The Latest Progress in Spark Telegraphy" before the general meeting of the Verein Deutscher Ingenieure at Kiel, Germany. He spoke of the latest systems of wireless-telegraph apparatus made by the Allegemeine Elektricitäts Gesellschaft and of the possibilities to be expected from space telegraphy in a practical way. At the conclusion of his lecture Professor Slaby showed that the future of spark telegraphy rests essentially in the possibility of producing high electrical pressures.

"What we employ at present for the purpose," said the lecturer, "is a very modest result, if we compare it with what Nikola Tesla, an investigator who lives at present [the lecture was delivered recently, but was evidently prepared some time ago] as a hermit, has shown on the peaks of the Rocky Mountains to very few intimates. Not having been an eye witness, I can only judge from a few photographs which Mr. Tesla sent me a few days ago as a token of friendly consideration. You can see him here for your self [in the accompanying illustration] in his lonely cabin surrounded by artificially produced spark discharges which overshadow everything our most daring imagination might dream of. It is to be hoped that he will put his theoretical knowledge and eminent technical power at the disposal of the practical service of spark telegraphy. We could then expect an immense advancement, which could be placed at the side of the first perception of Marconi.

TESLA'S HIGH-POTENTIAL WORK.

"It has been said that Tesla has not derived any practical results from his experiments, and many have doubted his ability to produce results on account of the poetic and fantastic remarks which he circulated in the daily press. But in the face of the wonderful demonstrations which nature has revealed to us in the mysterious play of the electric spark one involuntarily turns poet. Even such a serious savant as Professor Ayrton cannot restrain himself from day dream, as follows:

"'The day will come, when we are forgotten, when copper wires, gutta-percha coverings and iron armoring will be found only in museums. Then will man, when he desires to speak to his friend and knows not where he is, call with electric voice, which only his friend, who possesses the correspondingly tuned electric ear, can hear. He will ask: "Where art thou?" And the answer will ring into his ear: "I am in the deeps of the mine," or "on the peaks of the Andes" or "on the boundless ocean." Or perhaps no voice will respond, and he knows then that his friend is dead.'

"But science lives eternal, and with the power of youth (so may we add), and draws, for century after century, new treasures from the inexhaustible horn-of-plenty of nature."

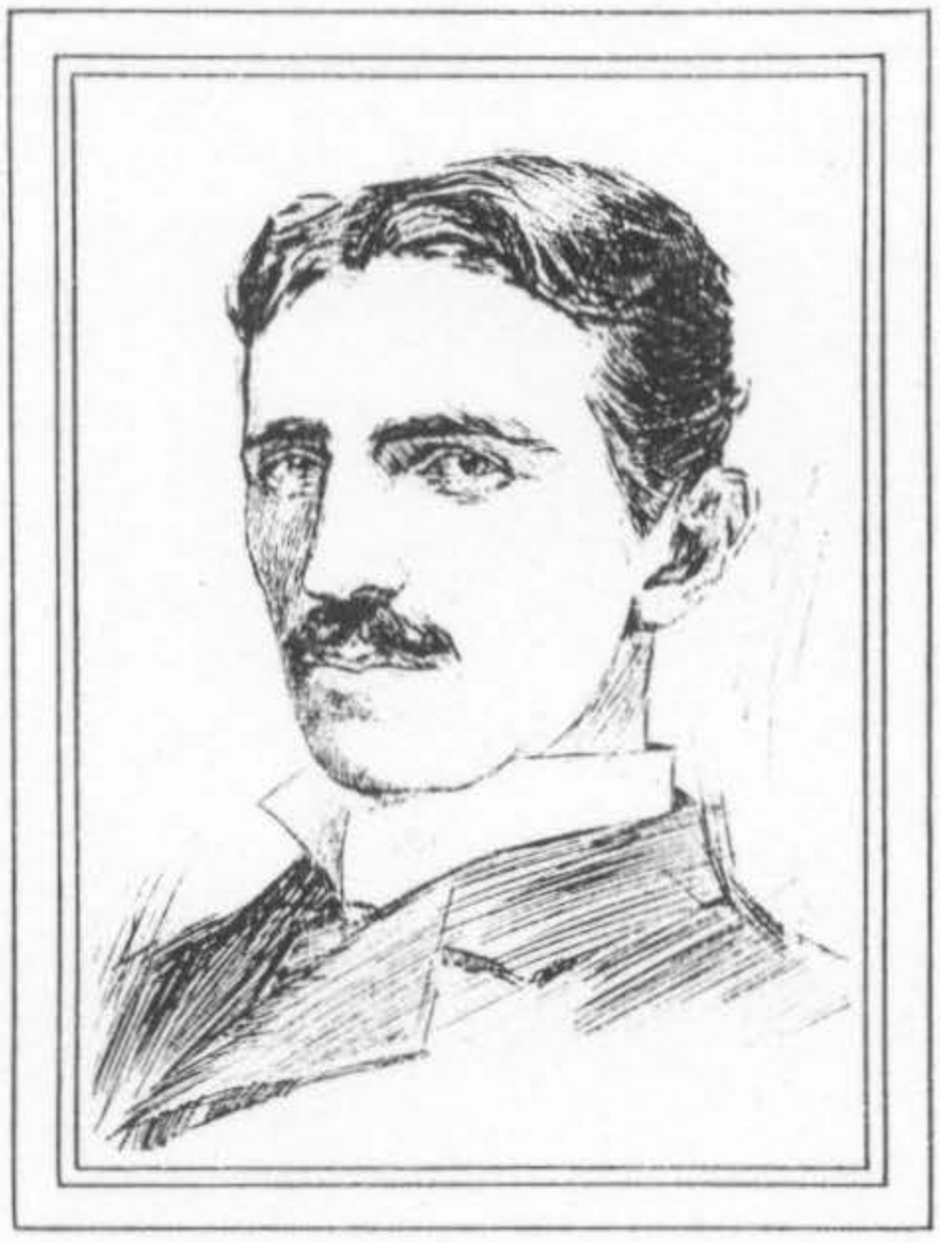
Mr. Tesla at Wardenclyffe, L. I.

Note was made recently of the intention of Mr. Nikola Tesla to install a wireless telegraph station for ocean work, at Wardenclyffe, on the north shore of Long Island, and it would now appear that this move on his part may be the beginning of a new industrial center. A circular has just been issued by the Wardenclyffe Building Company, from which some interesting details are gleaned. The place is about 65 miles from New York, or about 1½ hours by fast train on the Long Island Railroad. The company has purchased over 200 lots, and is offering its stock for sale at $100 per share, expecting to pay 15 per cent dividends. As to Mr. Tesla's part in the matter, the circular says: "This property was purchased from the North Shore Industrial Company, which owns an estate of something more than 1600 acres adjoining, under an agreement that the Wardenclyffe Building Company shall have the first right and privilege to do all building and make all constructional improvements of said North

Shore Industrial Company, and shall have the first right of purchase of any additional land offered by it for sale, by and under which *contractual rights large profits will be realized in the future.* In addition to this exceptional advantage, Mr. Nikola Tesla, the foremost electrician of the age, whose achievements in electrical science eclipse in practical importance all other discoveries of the century, has just closed a contract to expend at Wardenclyffe a very large sum of money in constructing electrical laboratories and the main station for his wireless telegraphy system of communication with Europe and Australasia. This development will require a large number of houses for the accommodation of the several hundreds of people whom Mr. Tesla will employ."

Mr. James S. Warden is authority for the statement that the Tesla factory will be 100 ft. square, supplemented by a "wireless" tower 350 ft. high. The walls are already being rapidly run up. Mr. Tesla in addition to the 200 acres on which his factory stands has preempted another 400 acres. The factory will be devoted to the manufacture of electrical instruments invented by Mr. Tesla, of extreme delicacy and complexity. Some 50 hands are to be at work shortly, but, according to Mr. Warden, the ultimate number spoken of is 2000 to 2500. Mr. Tesla is expected to occupy a cottage opposite the Wardenclyffe Inn, which is now being prepared for him. It is said that Mr. Charles R. Flint, the well-known merchant, etc., is back of the real estate enterprise.

The Junior Mumsey November 1901



NICOLA TESLA.

BY ELIOT LORD.

A CHARACTER SKETCH OF A STRANGE GENIUS WHO LIVES IN A STRANGE WORLD—HIS CAREFUL SCIENTIFIC TRAINING, SOME OF THE WONDERS HE HAS WROUGHT, AND HIS DREAMS OF THE FUTURE.

NICOLA TESLA and his associates are now building great signal and receiving stations on the Atlantic coast, in this country and Europe, with the declared purpose of sending commercial wireless messages across the ocean before the end of the present year. This is only the preface, in Tesla's view, to the despatch of like messages to any point on the face of the globe, and the possible opening of communication with the nearer planets, like Venus or Mars.

Many ordinary persons and some staid men of science are disposed to class Tesla with Phaethon, who tried to drive the chariot of the sun, or with Icarus, who was so proud of his wings that he flew up into the sky until the wax melted, and he dropped like a spent rocket into the sea. If the Servian genius should fall short, at the outset, in the execution of his design of sending electric signals across the Atlantic without the use of cables or transmitting wires, there will be a shaking of sage heads and testifying "We told you so." Then many will venture to say that the vaulting Tesla is intoxicated with the exuberance of his own conceits, or that he is actually disturbed in brain by the electric atmosphere in which he has enveloped himself, or by the stupendous bolts which he has so boldly shot through his body.

NICOLA TESLA, THE YOUNG SERVIAN WHOSE INVENTIONS AND EXPERIMENTS IN ELECTRICITY HAVE MADE HIM FAMOUS.

Tesla knows this very well, but the thought of what people may say of him or his ventures has never been jarring to his nerves. He is not without sensitiveness. On the contrary, he is deeply touched by cordial appreciation; but he holds that what most people call impossibilities are largely bugbears born of ignorance. When he is once convinced of the feasibility of what he has in hand, no battery of doubts would make him desist from carrying it into effect. This does not mean that he is obstinate against reason. But he is so persistent and resourceful that he has often overcome seemingly insuperable obstacles. In his present undertaking, he has already a practical demonstration of success in sending a wireless message over a stretch of six hundred miles. After this determination of the correctness of the principles in the construction of his signaling system, the extension of distance is with him a matter of detail — the perfecting of the correspondence and sen-

sitiveness of recording instruments. Personally, he has absolutely no fear of failure.

Whatever the issue of his present venture may be, he is entitled to a suspension of judgment until success or failure is proven. No living man has shown any deeper insight into the unfathomed nature and adaptabilities of electricity. No man of his years, probably, has devoted so many hours to the study of electricity as a science in all its varied applications, and few can rival his quickness of apprehension. If he is cocksure of any conclusion in this field, he has certainly an array of reason and evidence in support of his judgment. Moreover, he is not given to vain pretense. No investigator is more modest in his bearing, and no one has been more frank and honest in acknowledging his indebtedness to comrades in the same field or in defining the limits of his attainments. He has never knowingly sought credit for what he has not done.

Undoubtedly he has suffered in reputation from his own offhand speaking and writing. He has not always troubled himself to define precisely what he means in his ready flow of words. Time with him is an infinite stretch, and his anticipation of what men may do is not a prediction of what they will do tomorrow, or next year, or even in the next century. In writing of the probable development of the use of aluminum, for example, he used the word "soon" in a sense so differing from the ordinary that his statement was ridiculed by a leading technical journal. Tesla didn't care enough about the matter to explain his real meaning in any answer. He never denies anything, no matter how absurd, that is written about him. Some irresponsible writers have taken advantage of this, and placed in his mouth outrageously absurd statements which he never uttered; and the alleged interviews that appear constantly in newspapers have done more harm to his standing before the lay world than anything else. They have led many people to look upon Tesla as a *poseur*—a seeker after notoriety. Nothing could be farther from the truth. He does not know of one tenth that is written about him outside of the technical journals.

He has little apparent sensitiveness to attack or ridicule—largely, perhaps, because of his strong vein of humor, as well as the observant sense which led Dr. Johnson to remark that "no man was ever written down except by himself." His temper is naturally buoyant, and, though he can assume marked reserve and dignity when he chooses, he is always quite simple and unaffected in manner.

For a better understanding of what he is now proposing to do and what other aims he has, it is essential to recall who he is and how he has worked.

TESLA'S INHERITANCE OF GENIUS.

Nicola Tesla was born in Smiljan, a town of Lika, a district of southern Austria, near Fiume. He likes to mark the provincial distinction. "I am a Likan by birth," he says. "A Servian? Yes, roundly speaking, as Montenegrins are Servians. Our type is marked like those mountaineers, tall, lean, sinewy, strong—the transmission of the old Slavic physique."

Of this type he might stand as a model. His face is oval, his forehead high and full, and his features generally shapely, though his prominent cheek bones and hollow cheeks are racial. His eyes are dark hazel, not large, but brilliant, and somewhat deeply set. He speaks with animation when he is interested, and his face is then very expressive; but when he is bored all expression vanishes, and while his eyes are open, their sense seems to be shut. The flashing change from immobility to life is peculiar.

For generations the Teslas have been men of mark in their province. Nicola's grandfather fought under Napoleon. His son, Milutin, father of Nicola, was a popular poet before entering the church, in which he rose to the foremost distinction. His varied learning and his proficiency as a linguist were a marvel even to the Likans, who think little of speaking and writing three or four languages. As a Greek scholar, he was second only to Abraham Santa Clara, the most famous preacher of Hungary. His memory was extraordinary. "My father," says Tesla, "knew all our national poetry by heart."

Nicola may trace to his father's impress his own poetic expression and facile mastery of languages, but it is his mother whom he more nearly resembles. Her maiden name was Georgina Mandic. Her family is of the oldest in Hungary, and was long of mark in the church, in which her brother was a bishop. Her father also was a priest, of high standing and of remarkably advanced ideas—a scientific student and inventor, strongly bent on improving the habits of life of his poorer parishioners. He taught them the value of sanitation, and risked his life fearlessly in fighting the spread of disease.

His daughter was no less ardent in sympathy and service. She was only seventeen when the black plague ravaged the country, but she was already an expert and fearless nurse. When a neighbor's family was prostrated by the epidemic, and all the servants fled, she went into the house alone, soothed the last hours of the dying, and when father, mother, and children died, she prepared them for burial. Like her father, she was fond of scientific inquiry, and naturally inventive. Her talent had a practical bent, and she designed a weaving machine for use in her own house. Her eye was so keen and her hands so deft that almost any kind of mechanical work was easy for her. She did in sport feats that would baffle most jugglers. When she was sixty five years old, her son says, she would pluck out an eyelash and tie three knots in it. No woman, he thinks, was ever more surely a helpmate to a husband, and no mother was more devoted to her children.

THE BOYHOOD OF NICOLA TESLA.

Nicola was the second son, one of eight children, of whom six were girls. His elder brother was a lad of extraordinary promise. When he had finished his course in the lyceum, the rector and the full staff of professors accompanied him home, as a mark of the highest honor in their power to show. But a brilliant career was cut short, when he was barely eighteen, by a fall from his horse. Nicola was only a boy of four at the time, but he remembers the scene with the utmost vividness—the dash of the frightened horse and its return, and his mother running over the field and bearing home his brother, mortally hurt.

In the years that followed, the father and mother saw the younger son fulfilling the promise of the older, but every-*thing of note the child did brought tears* to their eyes in recalling his dead brother.

From babyhood Nicola Tesla has been abnormally sensitive to impressions. His earliest recollection is of some one shaking keys before his eyes, while, at the same time, a bell was ringing. To this day whenever there is a rattle of keys near him, he hears the sound of a bell. Up to his twentieth year the sight of anything round and polished was nauseating, and he is still unpleasantly affected by the sight of smooth, round objects. If he takes a goblet of water, he prefers cut glass to molded or blown glass.

He was further troubled by a strange affection of the eye, causing the rising of images so persistent that they marred the vision of real objects, and disturbed his mind. Whenever an object was named to him, its image would appear, at once, so vividly before his eyes that he often believed it real. This illusion caused him such discomfort that he tried his best to break it, but did not succeed until he was twelve years old. Then, for a time, he was able to banish the images, but they have since returned, though less persistently. His later observations have convinced him that these images are really the recalling of former visual impressions, consciously or unconsciously received.

He learned to count almost as soon as he could walk, and has been strangely impelled to keep count of his steps; so the stretches covered in his rambles come up in his mind as chains of steps. His measure of the Brooklyn Bridge is twenty seven hundred steps. He will count, too, any other repeated motion that he makes. He even numbers his bites in eating, and whatever he counts he is impelled to divide by three, or the square or cube of three, if possible. Whatever meets his eye, a house, a ship, a cloud, a mountain, impels him to a mental calculation of its cubic contents.

He constructs in his mind whatever he designs, even to the minutest detail,

but his hand is not ready in committing his designs to paper. He has an ideal, and is impatient of any deviation from it, even if it is merely the slope of a letter. So he may begin to write and tear up fifty sheets of note paper, if the slope of a line is vexing.

Going to school when he was five, he was quick to learn in any study attractive to him. In the schools of Austria Hungary, the first place is given to mathematics, supplemented in the more advanced schools by physics. Languages, history, bookkeeping, and drawing are the other leading features of the school course. Mathematics was of absorbing interest to Nicola, and he applied himself with energy to all other branches of study except drawing, which he disliked. When he was graduated from the lyceum at Carlstadt, the head master told him that he would have broken the record if he had been a good draftsman.

AT THE GRATZ POLYTECHNIC SCHOOL.

Just as he was leaving school there was an epidemic of cholera, and he was taken sick as he went up the steps to his home. Dropsy developed from this attack. The attending physician would give his parents no hope, but, in the intervals of his fainting from weakness, the boy told his father that he would get well if he could have the hope of going to the Polytechnic School at Gratz instead of preparing to enter the service of the church—the career designed for him. When this promise was made, he began to recover, to the surprise of every one except himself, and, before long, he was able to enter the school of his choice, one of the oldest technical schools in Europe.

Here, in lines of study appealing to his taste, there was no check to his application. He rose at three o'clock in the morning to begin his work, and did not go to bed till nearly midnight. In one year he ran through the courses of five years. No student before him had ever gone so fast. His professors admired his spirit, but tried to hold it in check. When the certificates of his progress were sent to his father, accompanying letters announced that the lad was killing himself by overwork. So his father never expressed any satisfaction with his son's progress, but wrote to him discouragingly, and insisted on his remaining in school for the full five years of the course. The first year's work left so little to be mastered in the regular course of study that for the next three years Tesla was delving in the libraries and undertaking special lines of research.

THE BEGINNING OF TESLA'S CAREER.

The study of electricity attracted him greatly, and he availed himself eagerly of the instruction of Professor Poeschl and other leading physicists. From Gratz he went to Prague to continue his studies for two years longer. "I was eighteen years at school," he says. The patient perseverance shown in laying such a foundation for his practical undertakings is characteristic. So, too, was his first occupation after leaving school.

The first opening offered him was that of a draftsman in the government railway service at Budapest. "This seemed to me," he says, "the irony of fate, a chance to put my worse foot forward; but I wanted work whether I liked it or not." After showing his proficiency in varied telegraphic work, his first signal opportunity came in the call to install one of the largest telephone stations in Europe at Budapest. Then the range of his proficiency was further shown in his engagement to put an electric lighting plant and stations in Strasburg, one of the most elaborate in the world at that time. Shortly after this successful installation he went to Paris, and made such important improvements in dynamos for the Edison Company that he was engaged to continue his work in this country, and crossed the Atlantic in 1884.

Outside of his accomplishments in the advance of electric lighting, he was particularly devoted to the investigation of the problem of the transmission of power by electric agencies. This had been pressing on his mind from the day when the working of the Gramme machine was first demonstrated to him by Professor Poeschl at Gratz. When he saw the production of a magnetic pole by the revolving of a cumbrous, wire wound

wheel or ring, the thought came to him: "Why should it not be possible to produce a magnetic whirl instead of an inert, static thing?" Would it not be far better, in other words, if one could make the magnetic force go round instead of the ponderous ring? Surely, but how? It is much simpler to conceive a grand transformation than to effect one. But Tesla was not deterred by the perplexities of the task. Year by year he advanced nearer to its attainment, and in 1883 he constructed the first working model of his perfected design, technically known as the Tesla rotating field.

One of the most amusing sights in his laboratory today is the demonstration of this conversion. Older children than *Toddy* would be puzzled to find out what makes the things go round when Tesla sets spindles and tops and balls revolving and circling about within the invisible ring of his rotating magnetism. "See my parody of the earth and the planets," says Tesla, dropping globes of various sizes into the ring. "Now you may see the spinning reversed;" and he sets spindles outside the ring that begin to revolve in the opposite direction. "Columbus, you know, made an egg stand on end by breaking the shell. Now, I can make eggs stand on end without breaking shells, as you see this one spinning off on its point." So he juggles in boyish spirit with his discovery, but it is none the less one of the prime factors in the present successful conversion and transmission of energy. More than any other invention, it rendered practicable the harnessing of the falls of Niagara, and the utilization of their power in electric service many miles away.

THE PURPOSES OF TESLA'S WORK.

In the perfecting of this device and other adaptations for the electric transmission of power, Tesla was largely engrossed until 1887, when his patents were purchased by the Westinghouse Company. His contribution to the perfecting of electric converters and transmitters was soon universally recognized to be of the foremost importance. If his bent had been towards money making, he might have piled up a fortune; but, while he was not indifferent to the winning of money, he had higher ambitions, and money is never likely to be more to him than the means that must be used to reach the ends that he aims at.

"I have no time to make money," said Agassiz with noble sincerity. It cannot be justly doubted that Tesla, without any pretense of unselfishness, has been possessed by a like spirit. To work is with him an impulse of conscience. In his view, the betterment of the conditions of living, and the advance of humanity, depend on the increase of human energy. "Persistent effort, useful and accumulative, with periods of rest and recuperation aiming at higher effiecieney," is the way he sums up his rule of living, but the periods of rest are very short and very few.

Broadly speaking, there are three main requisites, in his mind, for the increase of energy—food, peace, work. It has been his constant study to promote these essentials. From his point of view, the slaughter of animals is commonly wanton and cruel, for the use of meat is economically wasteful, if its nutriment is compared with some plant foods. He thinks that oatmeal is superior to meat, weight for weight, in flesh, bone, and brain building, while it has the obvious advantage in cheapness. So he is an ardent advocate of vegetarianism, and goes so far as to attribute animal instincts and appetites, which are drag weights upon mental and moral progress, to the consumption of animal food. Thus one of his prescriptions for human progress is a radical reform in the character of food.

THE CHEAP PRODUCTION OF NITROGEN.

He thinks that with this economic and helpful change there would be a material advance; but the advance may be immensely extended by increasing the productivity of the soil. While recognizing the high importance of irrigation, the preservation of forests, and other aids to this end, the prime requisite, in his judgment, is artificial fertilization, especially by the cheap production of the compounds of nitrogen. He looks to the atmosphere as the chief available source of nitrogen in practically inexhaustible amounts. How to

extract and fix the nitrogen is a problem, therefore, which he has long labored to solve.

There is great difficulty in it, for this element is so extraordinarily inert that it will not combine even with oxygen under normal conditions. But Tesla has demonstrated that electricity is so stimulating to dormant affinities that nitrogen electrically excited will burn. In 1891 he showed the feasibility of the oxidation of nitrogen in a small way by the production of a novel form of electric flame, named "St. Elmo's hot fire." The electric discharge of flame produced was only three or four inches in length, and the combustion was comparatively trivial and wasteful. It was necessary to extend it greatly to make the utilization of nitrogen of any practical service.

This extension Tesla has succeeded in effecting, greatly stimulating the chemical activity of the electric brush discharge by using electric currents of extremely high frequency or rate of vibration. Without following the technical steps of his advance, it is sufficient to note that he has succeeded in developing the insignificant brush discharge, a few inches long, into "a marvelous electrical phenomenon—a roaring blaze, devouring the nitrogen of the atmosphere and spanning a distance of seventy feet."

He has now made it practicable, as he says, to oxidize the atmospheric nitrogen in practically unlimited quantities by the use of cheap mechanical power and simple electrical apparatus. In this way many compounds of nitrogen may be manufactured all over the world, and by means of these compounds the soil may be fertilized and its productiveness indefinitely increased, assuring an abundance of cheap and helpful food. If future developments sustain his claim, this service alone should bring to him imperishable honor.

OTHER IRONS IN TESLA'S FIRE.

His undertaking for the promotion of peace may be no less notable. It was his idea to produce an arm for attack, adaptable to submarine and aërial warfare, so formidable that its development will ultimately make war a mere contest of machines—a condition that must be reached, to his mind, before permanent peace can be secured. He has been constructing automatic machines in the form of a torpedo to be completely controlled by the impress of electric vibrations. The possible variations and stretch of this design, in Tesla's view, are so far reaching that all fighting on sea and land may be carried on by these electrified automata. To the ordinary reader all this seems more incredible than any conceit of the romancers, but who dares say that it may not again be demonstrated that truth is stranger than fiction?

In the extension of wireless telegraphy there is to be a demonstration of the novel force which Tesla has been adapting to the production of nitrogen compounds and automatic engines of war. Twelve years ago he began the experiments which have led to his present undertaking, by studying the possibilities offered by extremely rapid electrical oscillation, and undertaking the construction of special machines for this investigation. One of his first observations was the effect of rapid electric oscillations on the human body. In his own person he demonstrated repeatedly that powerful electrical discharges of several hundred thousand volts, which were then considered absolutely deadly, could be passed through a man's body without any injury. He has produced oscillations of such intensity that while circulating through his arms and chest they have melted wires that joined his hands. Now he says that he would not hesitate to transmit through his body with such very rapidly vibrating electric currents the entire electrical energy of the dynamos now working at Niagara. The results of this application are now utilized in medical service, and promise to be of much importance.

The production of light by means of these electric oscillations was another signal advance which promises to lead to an ideal system of electric illumination by vacuum tubes, dispensing with the renewal of lamps or incandescent filaments. Already, as Tesla says, he has succeeded in lighting in this manner from four to five hundred lamps at once, and could light as many more. The efficiency of the light increases in propor-

tion to the rate of the oscillations, and its commercial success is therefore dependent on the economical production of high electrical vibrations. This production Tesla is confident of effecting.

A NEW FORM OF WIRELESS TELEGRAPHY.

In line with these advances was the adaptation of electric oscillation to wireless telegraphy. In its basic principle the system devised by Tesla is very simple. Imagine two tuning forks set up on opposite sides of a large room. To the lower prong of each of these forks a piston is attached, fitting in a cylinder. Both cylinders communicate with a reservoir with elastic walls—closed at the top and filled with a light and incompressible fluid. If a prong of one of these tuning forks is struck repeatedly, the small connected piston will be vibrated and the vibrations transmitted through the fluid in the reservoir to the opposite fork, which is "tuned" precisely alike. This vibration can readily be utilized to make an electric record of a message.

Now suppose, in place of common tuning forks with piston attachments, that vertical wires are substituted. Let the earth take the place of the closed reservoir with elastic walls, and let electricity be the light and incompressible fluid. Then, instead of striking the forks, if electrical oscillations are produced in one vertical wire, used as a transmitter, they will spread through the ground and reach the distant vertical receiving wire, setting a sensitive device in action to record messages. By a simple provision, each of the two wires can be used in turn to send and receive the messages. By employing relay stations with "tuned" circuits, it will be practicable, as Tesla holds, to transmit signals to any point of the globe.

For practical service it was necessary to design and complete an efficient apparatus for the production of very powerful electrical oscillations. This was effected by a novel combination of an electric condenser with a transformer or induction coil. The electrical oscillator thus made is of tremendous power and still greater possibilities. By its means an electric discharge or flash more than one hundred feet long has been made, and Tesla anticipates the production of flashes one hundred times as great. With its aid he has produced electrical movement at the rate of one hundred thousand horse power, and he says that rates of ten million horse power are easily practicable. By this agency not only can telegraphic messages be transmitted across the ocean without cables, as he claims and proposes to demonstrate, but the transmission of thousands of horse power of electric energy may be made through the atmosphere over hundreds and even thousands of miles.

It is certain that the world will watch intently the first public trials of this marvelous system for developing wireless telegraphy.

Tesla's Method of Increasing the Intensity of Electrical Oscillations.

Nikola Tesla still continues his interesting experiments with electrical vibrations, upon which he has been engaged for the last 10 years. Among the patents issued from the United States Patent Office on October 22d was one granted to him for "Means for Increasing the Intensity of Electrical Oscillations." The patent is numbered 685,012, and the application for it was filed March 21, 1900, and renewed July 3, 1901. Mr. Tesla describes his invention in the following language:

"In many scientific and practical uses of electrical impulses or oscillations—as, for example, in systems of transmitting intelligence to distant points—it is of great importance to intensify as much as possible the current impulses or vibrations which are produced in the circuits of the transmitting and receiving instruments, particularly of the latter.

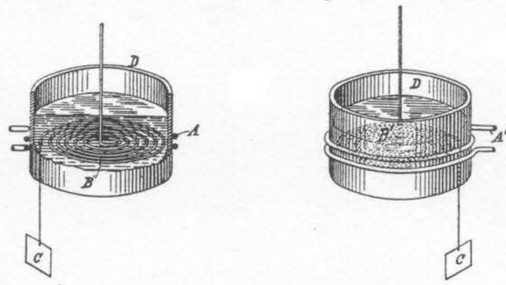
"It is well known that when electrical impulses are impressed upon a circuit adapted to oscillate freely the intensity of the oscillations developed in the same is dependent on the magnitude of its physical constants and the relation of the periods of the impressed and of the free oscillations. For the attainment of the best result it is necessary that the periods of the impressed should be the same as that of the free oscillations, under which conditions the intensity of the latter is greatest and chiefly dependent on the inductance and resistance of the circuit, being directly proportionate to the former and inversely to the latter. In order, therefore, to intensify the impulses or oscillations excited in the circuit—in other words, to produce the greatest rise of current or electrical pressure in the same—it is desirable to make its inductance as large and its resistance as small as practicable. Having this end in view, I have devised and used conductors of special forms and of relatively very large cross-section; but I have found that limitations exist in regard to the increase of the inductance as well as to the diminution of the resistance. This will be understood when it is borne in mind that the resonant rise of current or pressure in a freely oscillating circuit is proportionate to the frequency of the impulses, and that a large inductance in general involves a slow vibration. On the other hand, an increase of the section of the conductor with the object of reducing its resistance is, beyond a certain limit, of little or no value, principally because electrical oscillations, particularly those of high frequency, pass mainly through the superficial conducting layers, and, while it is true that this drawback may be overcome in a measure by the employment of thin ribbons, tubes, or standard cables, yet, in practice, other disadvantages arise, which often more than offset the gain.

"It is a well-established fact that as the temperature of a metallic conductor rises its electrical resistance increases, and, in recognition of this, constructors of commercial electrical apparatus have heretofore resorted to many expedients for preventing the coils and other parts of the same from becoming heated when in use, but merely with a view to economizing energy and reducing the cost of construction and operation of the apparatus.

"Now I have discovered that when a circuit adapted to vibrate freely is maintained at a low temperature the oscillations excited in the same are to an extraordinary degree magnified and prolonged, and I am thus enabled to produce many valuable results which have heretofore been wholly impracticable.

"Briefly stated, then, my invention consists in producing a great increase in the intensity and duration of the oscillations excited in a freely vibrating or resonating circuit by maintaining the same at a low temperature.

"Ordinarily, in commercial apparatus, such provision is made only with the object of preventing wasteful heating, and in any event its influence upon the intensity of the oscillations is very slight and practically negligible, for, as a rule, impulses of arbitrary frequency are impressed upon a circuit, irrespective of its own free vibrations, and a resonant rise is expressly avoided.



"My invention, it will be understood, does not primarily contemplate the saving of energy, but aims at the attainment of a distinctly novel and valuable result—that is, the increase to the greatest practicable degree of the intensity and duration of free oscillations. It may be usefully applied in all cases when this special object is sought, but offers exceptional advantages in those instances in which the freely oscillating discharges of a condenser are utilized.

"The best and most convenient manner of carrying out the invention of which I am now aware is to surround the freely vibrating circuit or conductor, which is to be maintained at a low temperature, with a suitable cooling medium, which may be any kind of freezing mixture or agent, such as liquid air, and in order to derive the fullest benefit from the improvement the circuit should be primarily constructed so as to have the greatest possible self-induction and the smallest practicable resistance, and other rules of construction which are now recognized should be observed. For example, when in a system of transmission of energy for any purpose through the natural media the transmitting and receiving conductors are connected to earth and to an insulated terminal, respectively, the lengths of these conductors should be one-quarter of the wave length of the disturbance propagated through them.

"In the accompanying drawing I have shown graphically a disposition of apparatus which may be used in applying practically my invention.

"The drawing illustrates in perspective two devices, either of which may be the transmitter, while the other is the receiver. In each there is a coil of few turns and low resistance, designated in one by (A) and in the other by (A′). The former coil, supposed to be forming part of the transmitter, is to be connected with a suitable source of current, while the latter is to be included in circuit with a receiving device. In inductive relation to said coils in each instrument is a flat, spirally wound coil (B) or (B′), one terminal of which is shown as connected to a ground plate (C), while the other, leading from the center, is adapted to be connected to an insulated terminal, which is generally maintained at an elevation in the air. The coils (B B′) are placed in insulating receptacles (D), which contain the freezing agent, and around which the coils (A) and (A′) are wound.

"Coils in the form of a flat spiral, such as those

TESLA'S METHOD OF INCREASING THE INTENSITY OF ELECTRICAL OSCILLATIONS.

described, are eminently suited for the production of free oscillations; but obviously conductors or circuits of any other form may be used, if desired.

"From the foregoing the operation of the apparatus will now be readily understood. Assume, first, as the simplest case that upon the coil (A) of the transmitter impulses or oscillations of an arbitrary frequency and irrespective of its own free vibrations are impressed. Corresponding oscillations will then be induced in the circuit (B), which, being constructed and adjusted, as before indicated, so as to vibrate at the same rate, will greatly magnify them, the increase being directly proportionate to the product of the frequency of the oscillations and the inductance of circuit (B) and inversely to the resistance of the latter. Other conditions remaining the same, the intensity of the oscillations in the resonating circuit (B) will be increased in the same proportion as its resistance is reduced. Very often, however, the conditions may be such that the gain sought is not realized directly by diminishing the resistance of the circuit. In such cases the skilled expert who applies the invention will turn to advantage the reduction of resistance by using a correspondingly longer conductor, thus securing a much greater self-induction, and under all circumstances he will determine the dimensions of the circuit, so as to get the greatest value of the ratio of its inductance as to its resistance, which determines the intensity of the free oscillations. The vibrations of coil (B), greatly strengthened, spread to a distance, and on reaching the tuned receiving conductor (B′) excite corresponding oscillations in the same, which, for similar reasons, are intensified, with the result of inducing correspondingly stronger currents or oscillations in circuit (A′), including the receiving device. When, as may be the case in the transmission of intelligible signals, the circuit (A) is periodically closed and opened, the effect upon the receiver is heightened in the manner above described, not only because the impulses in the coils (B) and (B′) are strengthened, but also on account of their persistence through a longer interval of time. The advantages offered by the invention are still more fully realized when the circuit (A) of the transmitter instead of having impulses of an arbitrary frequency impressed upon it is itself permitted to vibrate at its own rate, and more particularly so if it be energized by the freely oscillating high-frequency discharges of a condenser. In such a case the cooling of the conductor (A), which may be effected in any suitable manner, results in an extraordinary magnification of the oscillation in the resonating circuit (B), which I attribute to the increased intensity as well as greater number of the high-frequency oscillations obtained in the circuit (A). The receiving coil (B′) is energized stronger in proportion and induces currents of greater intensity in the circuit (A′). It is evident from the above that the greater the number of the freely vibrating circuits which alternately receive and transmit energy from one to another the greater, relatively, will be the gain secured by applying my invention."

MR. TESLA'S method of utilizing electrical effects transmitted through earth or air is described in this issue, the description being based on a careful examination of six United States patents issued last week and being largely in the language of the inventor himself. Mr. Tesla has devised a novel method of "effecting during any desired time interval a storage of energy derived from such [long-distance electrical] impulses and utilizing the potential energy so obtained for operating a receiving device." The "storage device" which Mr. Tesla prefers to use is a condenser, which allows the energy of the succeeding impulses to be accumulated for a sufficient length of time and then discharged instantaneously in a manner said to be highly effective. The inventor says that by the use of his invention results hitherto unattainable in utilizing disturbances or effects transmitted very great distances through natural media may be readily attained. Perhaps this means that wireless transmission across the Atlantic is really in contemplation. At any rate, the patents are of great interest and contain within themselves their best interpretation.

Tesla's Utilization of Electrical Effects and Radiant Energy.

Following close upon the patent for "Means for Increasing the Intensity of Electrical Oscillations" that was granted to Nikola Tesla on October 22d (illustrated description of which was given in the Western Electrician of November 2d) comes a series of six patents relating to the utilization of radiant energy and effects transmitted through natural media, such as the air and earth, that, seemingly, are of much greater importance. These patents, numbered consecutively from 685,953 to 685,958, were issued by the United States Patent Office on November 5th. From their evident basic nature the patents may have an important bearing upon the project for the transmission of messages long distances through space, which Mr. Tesla is known to have been working upon for some time.

In his introductory remarks Mr. Tesla recognizes that in wireless telegraphy, as commonly known, the electrical impulses reach a very distant receiving station in an extremely feeble and attenuated condition. So extremely feeble are these impulses that it is easy to discern the limitations of wireless telegraphy as to-day practiced.

Generally expressed, Mr. Tesla seeks to achieve results hitherto unobtainable in utilizing the feeble electrical effects transmitted through the air or the earth, by accumulating in a "storage device" the energy of succeeding impulses for a sufficient interval of time to render the sudden liberation of the accumulated charge highly effective in operating a receiver. He uses as a "storage device" a condenser. This he deems the most efficient electrical storage device known to him for this purpose.

A crude illustration of the method underlying the patents may be taken by considering a small waterwheel and a tiny stream of water—so tiny that one could hardly see or feel it—a stream that comes really not in a steady stream but in impulses, so to speak, one little spurt of water at a time. The question of having this tiny stream of impulses, each impulse having but very little energy, move and drive a comparatively bulky waterwheel is somewhat analogous to the problem Mr. Tesla has undertaken to solve—that of utilizing the feeble electrical effects transmitted through a considerable distance. In the hydraulic analogy a solution would be to collect the water of the tiny stream in a reservoir, and, when enough has accumulated to produce the desired movement, to turn it upon the wheel. Mr. Tesla's solution of the electrical problem is to employ a "storage device"—preferably a condenser.

The six patents to be described may be considered in three sets of two each. In patent No. 685,954, the application for which was filed on August 1, 1899, and renewed on May 29, 1901, the inventor describes a "Method of Utilizing Effects Transmitted Through Natural Media." In describing his invention Mr. Tesla writes as follows:

"My invention is particularly useful in connection with methods and apparatus for operating distant receiving devices by means of electrical disturbances produced by proper transmitters and conveyed to such receiving devices through the natural media; but it obviously has a wider range of applicability and may be employed, for example, in the investigation or utilization of terrestrial, solar, or other disturbances produced by natural causes.

"Several ways or methods of transmitting electrical disturbances through the natural media and utilizing them to operate distant receivers are now known and have been applied with more or less success for accomplishing a variety of useful results.

"One of these ways consists in producing, by a suitable apparatus, rays or radiations—that is, disturbances—which are propagated in straight lines through space, directing them upon a receiving or recording apparatus at a distance, and thereby bringing the latter into action. This method is the oldest and best known and has been brought particularly into prominence in recent years through the investigations of Heinrich Hertz.

"Another method consists in passing a current through a circuit, preferably one enclosing a very large area, inducing thereby in a similar circuit situated at a distance another current and affecting by the same in any convenient way a receiving device.

"Still another way, which has also been known for many years, is to pass in any suitable manner a current through a portion of the ground, as by connecting to two points of the same, preferably at a considerable distance from each other, the two terminals of a generator and to energize by a part of the current diffused through the earth a distant circuit, which is similarly arranged and grounded at two points widely apart and which is made to act upon a sensitive receiver.

"These various methods have their limitations, one especially, which is common to all, being that the receiving circuit or instrument must be maintained in a definite position with respect to the transmitting apparatus, which often imposes great disadvantages upon the use of the apparatus.

"In several applications filed by me and patents granted to me I have disclosed other methods of accomplishing results of this nature, which may be briefly described as follows: In one system the potential of a point or region of the earth is varied by imparting to it intermittent or alternating electrifications through one of the terminals of a suitable source of electrical disturbances, which, to heighten the effect, has its other terminal connected to an insulated body, preferably of large surface and at an elevation. The electrifications communicated to the earth spread in all directions through the same, reaching a distant circuit, which generally has its terminals arranged and connected similarly to those of the transmitting source and operates upon a highly sensitive receiver.

"Another method is based upon the fact that the atmospheric air, which behaves as an excellent insulator to currents generated by ordinary apparatus, becomes a conductor under the influence of currents or impulses of enormously high electromotive force which I have devised means for generating. By such means air strata, which are easily accessible, are rendered available for the production of many desired effects at distances however great. This method, furthermore, allowed advantage to be taken of many of those improvements which are practicable in the ordinary systems of transmission involving the use of a metallic conductor.

"Obviously, whatever method be employed, it is desirable that the disturbances produced by the transmitting apparatus should be as powerful as possible, and by the use of certain forms of high-frequency apparatus which I have devised and which are now well known, important practical advantages are in this respect secured.

"Furthermore, since in most cases the amount of energy conveyed to the distant circuit is but a minute fraction of the total energy emanating from the source, it is necessary, for the attainment of the best results, that whatever the character of the receiver and the nature of the disturbances as much as possible of the energy conveyed should be made available for the operation of the receiver, and, with this object in view, I have, heretofore, among other means, employed a receiving circuit of high self-induction and very small resistance and of a period such as to vibrate in synchronism with the disturbances, whereby a number of separate impulses from

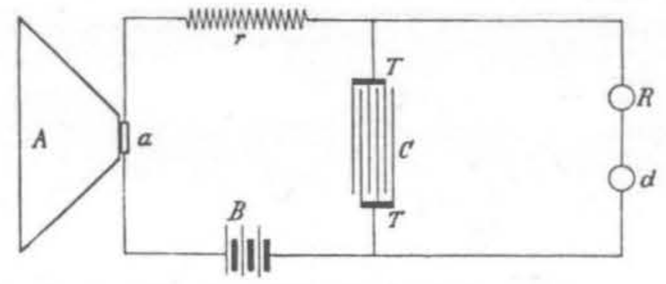


FIG. 1. TESLA'S UTILIZATION OF ELECTRICAL EFFECTS AND RADIANT ENERGY.—ARRANGEMENT OF RECEIVING APPARATUS.

the source were made to co-operate, thus magnifying the effect exerted upon and insuring the action of the receiving device. By these means decided advantages have been secured in many instances; but very often the improvement is either not applicable at all, or, if so, the gain is very slight.

"Evidently, when the source is one producing a continuous pressure or delivering impulses of long duration, it is impracticable to magnify the effects in this manner, and when, on the other hand, it is one furnishing short impulses of extreme rapidity of succession, the advantage obtained in this way is insignificant, owing to the radiation and the unavoidable frictional waste in the receiving circuit. These losses reduce greatly both the intensity and the number of the co-operative impulses, and, since the initial intensity of each of these is necessarily limited only an insignificant amount of energy is thus made available for a single operation of the receiver. As this amount is consequently dependent on the energy conveyed to the receiver by one single impulse, it is evidently necessary to employ either a very large and costly, and therefore objectionable transmitter or else to resort to the equally objectionable use of a receiving device too delicate and too easily deranged. Furthermore, the energy obtained through the co-operation of the impulses is in the form of extremely rapid vibrations, and, because of this, unsuitable for the operation of ordinary receivers, the more so as this form of energy imposes narrow restrictions in regard to the mode and time of its application to such devices.

"To overcome these and other limitations and disadvantages that have heretofore existed in such systems of transmission of signals or intelligence and to render possible an investigation of impulses or disturbances propagated through the natural media from any kind of source and their practical utilization for any purpose to which they are applicable, I have devised a novel method, which, broadly stated, consists in effecting during any desired time interval a storage of energy derived from such impulses and utilizing the potential energy so obtained for operating a receiving device.

"The best way of carrying out my invention which I at present know is to store electrical energy obtained from a suitable electrical generator in a condenser and to control the storage or the application of this energy by means of a sensitive device acted upon by the effects or disturbances, and thereby cause the operation of the receiver.

"The general principle underlying my invention and the operation of the various devices used will be clearly understood by a reference to the accompanying drawing (Fig. 1), which is a diagram illustrating a typical arrangement of apparatus which may be used in carrying my method into practice.

"In Fig. 1 (C) is a condenser, to the terminals (T) and (T) of which is connected a charging circuit including a battery (B), a sensitive device (a), and a resistance (r), all connected in series, as illustrated. The battery should be preferably of very constant electromotive force and of an intensity carefully determined to secure the best results. The resistance (r), which may be a frictional or an inductive one, is not absolutely necessary; but it is of advantage to use it in order to facilitate adjustment, and for this purpose it may be made variable in any convenient and preferably continuous manner.

"Assuming that the disturbances which are to be investigated or utilized for some practical end are rays identical with or resembling those of ordinary light, the sensitive device (a) may be a selenium cell properly prepared, so as to be highly susceptible to the influence of the rays, the action of which should be intensified by the use of a reflector (A), shown in the drawing. It is well known that when cells of this kind are exposed to such rays of greatly varying intensity they undergo corresponding modifications of their electrical resistance; but in the ways they have been heretofore used they have been of very limited utility.

"In addition to the circuit including the sensitive device or cell (a), another circuit is provided, which is likewise connected to the terminals (T) (T) of the condenser. This circuit, which may be called the 'receiving circuit,' includes the receiver (R), and in series with it a device (d) before referred to, which performs the duty of periodically discharging the condenser through the receiver.

"From the foregoing the operation of the apparatus as illustrated in Fig. 1 will be at once understood. Normally—that is, when it is not influenced by the rays at all or very slightly—the cell (a) being of a comparatively high resistance, permits only a relatively feeble current to pass from the battery into the condenser, and hence the latter is charged at too slow a rate to accumulate during the time interval between two succeeding operations of the device (d), sufficient energy to operate the receiver, or, generally speaking, to produce the required change in the receiving circuit.

"This condition is readily secured by a proper selection and adjustment of the various devices described, so that the receiver will remain unresponsive to the feeble discharges of the condenser, which may take place when the cell (a) is acted upon but slightly or not at all by the rays or disturbances; but if now new rays are permitted to fall upon the cell or if the intensity of those already acting upon it be increased by any cause, then its resistance will be diminished and the condenser will be charged by the battery at a more rapid rate, enabling sufficient potential energy to be stored in the condenser during the period of inaction of the device (d) to operate the receiver or to bring about any desired change in the receiving circuit when the device (d) acts.

"If the rays acting upon the cell or sensitive device (a) are varied or intermitted in any arbitrary manner, as when transmitting intelligence in the usual way from a distant station by means of short and long signals, the apparatus may readily be made to record or to enable an operator to read the message, since the receiver, supposing it to be an ordinary magnetic relay, for example, will be operated by each signal from the sending station a certain number of times having some relation to the duration of each signal. It will be readily seen, however, that if the rays are varied in any other way, as by impressing upon them changes in intensity, the succeeding condenser discharges will undergo corresponding changes in intensity, which may be indicated or recorded by a suitable receiver and distinguished irrespectively of duration.

"It will be observed that the condenser is an important element in the combination. I have shown that, by reason of its unique properties, it greatly adds to the efficacy of this method. It allows the energy accumulated in it to be discharged instantaneously, and therefore in a highly effective manner. It magnifies in a large degree the current supplied from the battery, and, owing to these features, it permits energy to be stored and discharged at practically any rate desired, and thereby makes it possible to receive in the retaining circuit very great changes of the current strength by impressing upon the battery current very small variations. Other means of storage possessing these characteristics to a useful degree may be employed without departing from the broad spirit of my invention; but I prefer to use a condenser, since, in these respects, it excels any other storage device of which I have knowledge.

"By carefully observing well-known rules of scientific design and adjustment of the instruments the apparatus may be made extremely sensitive and capable of responding to the feeblest influences, thus making it possible to utilize impulses or disturbances transmitted from very great distances and too feeble to be detected or utilized in any of the ways heretofore known, and, on this account, the method here described lends itself to many scientific and practical uses of great value."

Patent No. 685,956, the application for which is a division of the original application which included

[*Continued on page 326*]

Tesla's Utilization of Electrical Effects and Radiant Energy.

[*Continued from page 323.*]

the preceding patent, covers the "Apparatus for Utilizing Effects Transmitted Through Natural Media" and is essentially the same as the "method" patent just described.

To intensify the feeble and attenuated electrical effects referred to in the first patent, Mr. Tesla employs a method, the apparatus for which is diagramatically illustrated in Fig. 2. This method is patented under No. 685,953, while the apparatus therefor is covered by patent No. 685,955, its application being a division of the original "method" application, which was filed on June 24, 1899, and renewed on May 29, 1901.

This apparatus consists of a cylinder (A) of insulating material, which is moved at a uniform rate

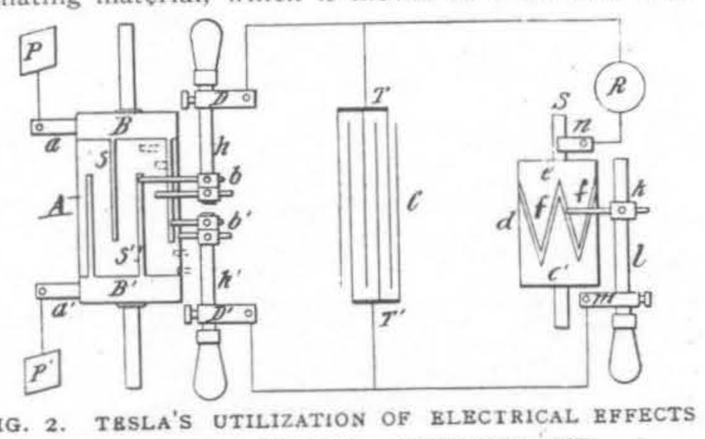

FIG. 2. TESLA'S UTILIZATION OF ELECTRICAL EFFECTS AND RADIANT ENERGY.—APPARATUS FOR INTENSIFYING EFFECTS.

of speed by clockwork or other suitable motive power, and is provided with two metal rings (B) (B'), upon which bear brushes (a) and (a'), which are connected, respectively, to the terminal plates (P) and (P'). From the rings (B) (B') extend narrow metallic segments (s) and (s'), which, by the rotation of the cylinder (A) are brought alternately into contact with double brushes (b) and (b'), carried by and in contact with conducting holders (h) and (h'), which are adjustable longitudinally in the metallic supports (D) and (D'). The latter are connected to the terminals (T) and (T') of a condenser (C), and are capable of angular displacement, as ordinary brush supports. The object of using two brushes, as (b) and (b'), in each of the holders (h) and (h'), is to vary at will the duration of the electric contact of the plates (P) and (P') with the terminals (T) and (T'), to which is connected a receiving circuit, including a receiver (R) and a device (d), which performs the duty of closing the receiving circuit at predetermined intervals of time and discharging the stored energy through the receiver.

In the present case this device consists of a cylinder (d), made partly of conducting and partly of insulating material (e) and (e'), respectively, which is rotated at the desired rate of speed by any suitable means. The conducting part (e) is in good electrical connection with the shaft (S), and is provided with tapering segments (f) (f), upon which slides a brush (k), supported on a conducting rod (l), capable of longitudinal adjustment in a metallic support (m). Another brush (n) is arranged to bear upon the shaft (S), and it will be seen that whenever one of the segments (f) comes in contact with the brush (k) the circuit, including the receiver (R), is completed and the condenser discharged through the same.

By an adjustment of the speed of rotation of the cylinder (d) and a displacement of the brush (k) along the cylinder the circuit may be made to open and close in as rapid succession and remain open or closed during such intervals of time as may be desired. The plates (P) and (P'), through which the electrifications are conveyed to the brushes (a) and (a'), may be at a considerable distance from each other and both in the ground or both in the air, or one in the ground and the other in the air, preferably at some height, or they may be connected to conductors extending to some distance or to the terminals of any kind of apparatus supplying electrical energy which is obtained from the energy of the impulses or disturbances transmitted from a distance through the natural media.

It is the function of the cylinder (A) with its brushes and connections to render the electrical impulses coming from the plates (P) and (P') suitable for charging the condenser by rectifying them when they are originally alternating in direction or by selecting such parts of them as are suitable when all are not.

When the apparatus is used in connection with the transmission of signals or intelligence, "it will, of course, be understood," says Mr. Tesla, "that the transmitter is operated in such a way as to produce disturbances or effects which are varied or intermitted in some arbitrary manner—for example, to produce longer and shorter successions of impulses, corresponding to the dashes and dots of the Morse alphabet—and the receiving device will respond to and indicate these variations or intermittences, since the storage device will be charged and discharged a number of times corresponding to the duration of the successions of impulses received."

Referring to the importance of this invention, Mr. Tesla says: "It will be seen that by the use of my invention results hitherto unattainable in utilizing disturbances or effects transmitted through natural media may be readily attained, since however great the disturbance of such transmission and however feeble or attenuated the impulses received enough energy may be accumulated from them by storing up the energy of succeeding impulses for a sufficient interval of time to render the sudden liberation of it highly effective in operating a receiver. In this way receivers of a variety of forms may be made to respond effectively to impulses too feeble to be detected or to be made to produce any sensible effect in any other way of which I am aware—a result of great value in scientific research, as well as in various applications to practical use."

The third set of Mr. Tesla's patents, Nos. 685,957 and 685,958, cover, respectively, the apparatus and the method of utilizing radiant energy. Applications for both were filed on March 21, 1901. The invention described bears a close connection to those described in the preceding patents and is exceedingly interesting and novel. In his description he says:

"It is well known that certain radiations—such as those of ultra-violet light, cathodic, Roentgen rays, or the like—possess the property of charging and discharging conductors of electricity, the discharge being particularly noticeable when the conductor upon which the rays impinge is negatively electrified. These radiations are generally considered to be ether vibrations of extremely small wave lengths, and in explanation of the phenomena noted it has been assumed by some authorities that they ionize or render conducting the atmosphere through which they are propagated. My own experiments and observations, however, lead me to conclusions more in accord with the theory heretofore advanced by me that sources of such radiant energy throw off with great velocity minute particles of matter which are strongly electrified, and therefore capable of charging an electrical conductor, or, even if not so, may at any rate discharge an electrified conductor, either by carrying off bodily its charge or otherwise.

"My present application is based upon a discovery which I have made that when rays or radiations of the above kind are permitted to fall upon an insulated conducting body connected to one of the terminals of a condenser, while the other terminal of the same is made by independent means to receive or to carry away electricity, a current flows into the condenser so long as the insulated body is exposed to the rays, and under the conditions hereinafter specified an indefinite accumulation of electrical energy in the condenser takes place. This energy, after a suitable time interval, during which the rays are allowed to act, may manifest itself in a powerful discharge, which may be utilized for the operation or control of mechanical or electrical devices or rendered useful in many other ways.

"In applying my discovery I provide a condenser, preferably of considerable electrostatic capacity, and connect one of its terminals to an insulated metal plate or other conducting body exposed to the rays or streams of radiant matter. It is very important, particularly in view of the fact that electrical energy is generally supplied at a very slow rate to the condenser, to construct the same with the greatest care. I use by preference the best quality of mica as dielectric, taking every possible precaution in insulating the armatures, so that the instrument may withstand great electrical pressures without leaking, and may leave no perceptible electrification

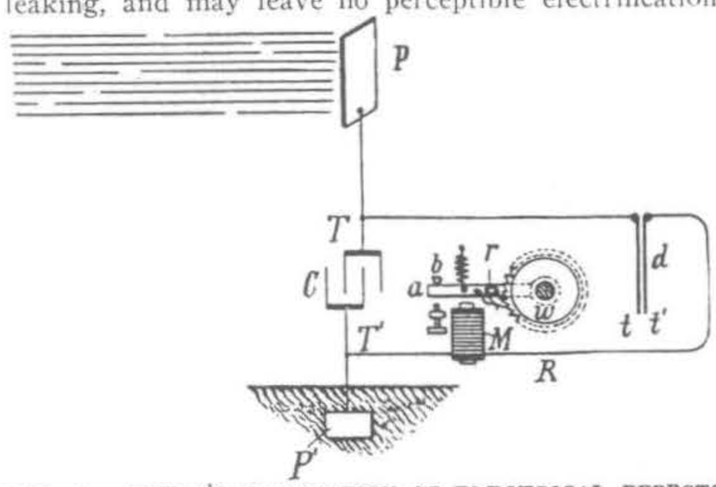

FIG. 3. TESLA'S UTILIZATION OF ELECTRICAL EFFECTS AND RADIANT ENERGY.—RECEIVING DEVICE FOR RADIANT ENERGY.

when discharging instantaneously. In practice I have found that the best results are obtained with condensers treated in the manner described in a patent granted to me February 23, 1897, No. 577,671.

"The rays or radiations which are to be utilized for the operation of the apparatus may be derived from a natural source, as the sun, or may be artificially produced by such means, for example, as an arc lamp, a Roentgen tube, and the like, and they may be employed for a great variety of useful purposes.

"My discovery will be more fully understood from the following detailed description and annexed drawing, to which reference is now made.

"Fig. 3 is a diagram showing typical forms of the devices or elements as arranged and connected in applying the method for the operation of a mechanical contrivance or instrument solely by the energy stored. (C) is the condenser, (P) the insulated plate or conducting body, which is exposed to the rays, and (P') another plate or conductor, all being joined in series, as shown. The terminals (T) (T') of the condenser are also connected to a circuit including a receiver (R) which is to be operated and a circuit-controlling device (d), which, in this case, is composed of two very thin conducting plates (t) (t'), placed in close proximity and very mobile, either by reason of extreme flexibility or owing to the character of their support. To improve their action, they should be enclosed in a receptacle from which the air may be exhausted. The receiver (R) is shown as consisting of an electromagnet (M), a movable armature (a), a retractile spring (b), and a ratchet wheel (w), provided with a spring pawl (r), which is pivoted to armature (a). The apparatus being arranged as shown, it will be found that when the radiations of the sun or of any other source capable of producing the effects before described, fall upon the plate (P) an accumulation of electrical energy in the condenser (C) will result. This phenomenon, I believe, is best explained as follows: The sun, as well as other sources of radiant energy, throw off minute particles of matter positively electrified, which, impinging upon the plate (P), communicate an electrical charge to the same. The opposite terminal of the condenser being connected to the ground, which may be considered as a vast reservoir of negative electricity, a feeble current flows continuously into the condenser, and, inasmuch as these supposed particles are of inconceivably small radius or curvature, and consequently charged to a relatively very high potential, this charging of the condenser may continue, as I have found in practice, almost indefinitely, even to the point of rupturing the dielectric. Obviously, whatever circuit controller be employed, it should operate to close the circuit in which it is included when the potential in the condenser has reached the desired magnitude."

The New York Tribune November 19, 1901

MR. TESLA'S LATEST PATENTS.

MEANS DEVISED TO INCREASE THE SENSITIVENESS OF RECEIVING APPARATUS IN WIRELESS TELEGRAPHY.

Several patents taken out by Nikola Tesla within the last few days are described by "The Electrical World and Engineer" and "The Western Electrician." They all represent methods and devices to be employed in wireless telegraphy, and relate exclusively to receiving apparatus, regardless of the transmitter or of the medium by which the impulses are conveyed.

Those who have studied Marconi's system know that at the receiving station a short circuit of wire is made to inclose a small "local" battery, an instrument called a "sounder" which ticks off the messages as in the Morse system, and a device invented by Branly and known as a "coherer." Under ordinary circumstances, the current from the battery is not strong enough to force its way around the circuit and to actuate the sounder. But when Hertz waves from some distant point reach the coherer they lessen its resistance and allow the sounder to respond. Now, when these waves come from too great a distance they are too weak to influence the coherer. The special object of Mr. Tesla's recent researches, therefore, has been to increase the effect of feeble impulses.

The most important expedient resorted to by him is to put into the receiving circuit a familiar bit of apparatus, a condenser. This acts like a storage battery, and intensifies the action of the incoming waves upon the sounder. Incidentally, there are one or two other attachments, of a purely mechanical and technical character, which need not be described here. They are designed to enable the condenser to do its work more effectively. One other idea, covered by a recent patent, deserves mention, however. It is intended for service only when the incoming signals are given by light, or radiance closely akin thereto. It is a well known property of selenium that when light falls upon it its electrical conductivity is increased. By putting a bit of this metal in his receiving circuit at the right point, Mr. Tesla makes it serve the same purpose that the coherer does in Marconi's system. It permits the local battery to act on the sounder.

TESLA AND TELEGRAPHY

TRANSMUNDANE MESSAGES FROM WARDENCLIFFE.

PROGRESS OF PREPARATIONS—POWER-HOUSE, TOWER AND MACHINERY

Since Mr. Tesla's purchase of land at Wardencliffe, Long Island, for a wireless telegraph station last summer, much progress has been made with his preparations. It is his intention not only to send messages from that point, but also to have a suitable laboratory for experimental work and a factory for the manufacture of instruments. After the system is once in operation, of course, it will be desirable to supply the requisite apparatus for equipping other stations. This, in the main, will be made at Mr. Tesla's own shops.

In designing the plant, therefore, both the needs of the future factory and laboratory, as well as the operation of the Wardencliffe telegraph station, have been kept in view. The principal building, in which power will be developed, has now been practically completed, and steam boilers and engines are on the spot, being installed as fast as possible. Owing to a variety of unforeseen causes, vexatious delays have been experienced. These have greatly tried Mr. Tesla's patience, although he takes such annoyances philosophically. For the operation of the instruments at the station he estimates that a hundred horsepower will be sufficient. To a novice this amount may seem excessive, but it must be remembered that Mr. Tesla expects to make his impulses felt at a distance of thousands of miles. Hence to his own mind this appears like a modest provision, though it has been adopted after elaborate calculation and experiment. It should be added that in order to admit of occasional change from one boiler and engine to another, this part of the plant will be duplicated at the outset.

The electrical machinery which is to be set up at Wardencliffe has not yet arrived, but will be put in place as soon as delivered. The dynamo can be made by outsiders. One very important instrument, known as a Tesla coil, or transformer, will be built in part by the inventor himself, and this will embody a number of recent improvements. All of the apparatus here mentioned will be installed at the surface of the earth.

Another feature of the Wardencliffe equipment will be a tower 150 feet high. At the present time the foundations are being laid. In the mean time the tower is being constructed in separate sections, away from the site on which it is eventually to rise. It is hoped that within three or four weeks the erection of that structure may be begun. It should then go ahead rapidly, although another month may possibly elapse before its completion. In view of the many delays already encountered, Mr. Tesla is exceedingly cautious about making predictions, even to himself. He also prefers not to go into details about the tower, although to some extent its function is indicated in his patents. There is a certain mathematical relation between the length of an upright conductor connected with the apparatus for developing Hertz waves and the length of the waves themselves. Then, too, some of the electricians who have engaged in this class of work have utilized an upright conductor for obtaining a storage of energy, or "capacity."

Mr. Tesla yesterday described the operation of telegraphy itself in something like these terms: "The current which I will use will be of the familiar alternating type. The energy which is generated in that form will be stored in a condenser, but after its discharge therefrom the intensity of the vibrations will be magnified ten thousand times. These vibrations will be of the kind best calculated for transmission through the earth, which is my real conductor. The energy thus developed will diffuse itself in all directions, but will tend to spread over the earth's surface, penetrating to a depth of four or five feet. At the receiving station I will provide means for magnifying the force of the incoming, but much weakened, vibrations a quarter of a million times."

When asked about his arrangements for having his first few messages received at some other place, Mr. Tesla preferred not to go into particulars, although he says that he has practically perfected his plans. The suggestion having been made to him that perhaps the Eiffel Tower might serve his purpose, he laughed and shook his head. He intimated that there were much better places. Although a tower is used at his transmitting station, the apparatus is really at the surface of the earth. In like manner the vibrations, after a long journey through the crust of the globe, would probably be more perceptible at sea level than at an elevation.

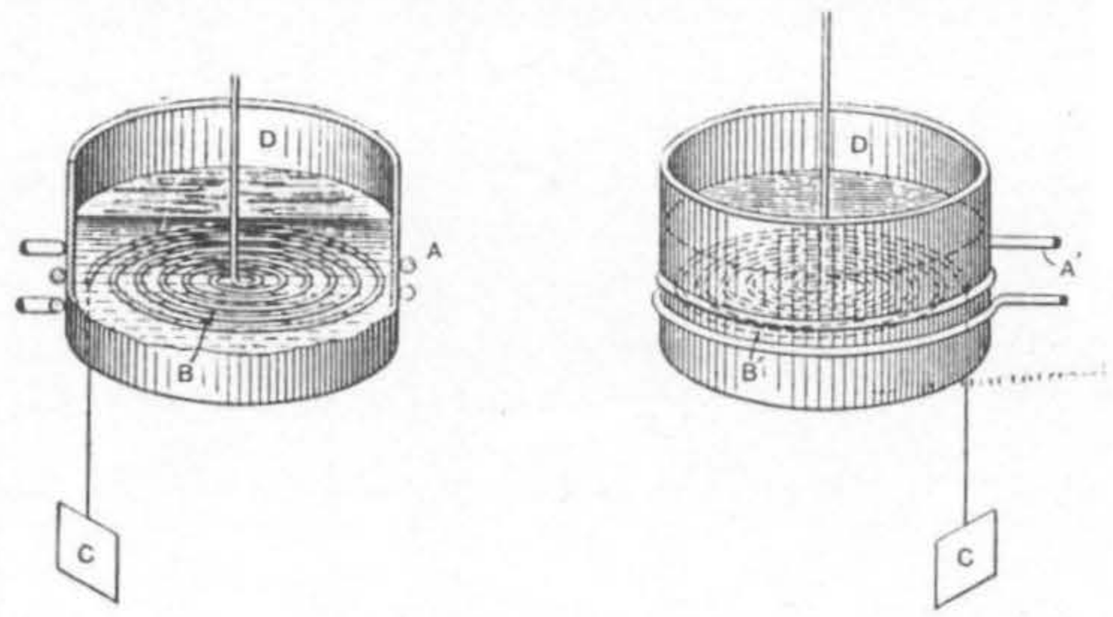
Wardencliffe is on the north shore of Long Island, eight or nine miles beyond Port Jefferson, and sixty-five or sixty-six from Brooklyn. A branch of the Long Island Railway extends through it to Wading River. There is a station at Wardencliffe.

Tesla's Recent Patents.

Nikola Tesla has received several patents for a "Method of Intensifying and Utilizing Effects Transmitted Through Natural Media." In one of his systems Tesla varies the potential point or region of the earth by imparting to it intermittent or alternating electrifications through one of the terminals of a suitable source of electrical disturbances which to heighten the effect, has its other terminal connected with an insulated body, preferably of large surface and at an elevation. Electrifications communicated to the earth spread in all directions, reaching a circuit which generally has its terminals arranged and connected similarly to those of the transmitting source, and which operates upon a highly sensitive receiver. Another of Tesla's methods is based upon the fact that the atmospheric air, which behaves as an excellent insulator to currents generated by ordinary apparatus, becomes a conductor under the influence of currents or impulses of enormously high electromotive force. By such means air strata, which are easily accessible, are rendered available for the production of many desired effects at distances. Although either method may be employed, it is obviously desirable that the disturbance should be as powerful as possible and should be transmitted with a minimum loss. The loss reduces greatly both the intensity and the number of the co-operative impulses, and since the initial intensity of each of these is necessarily limited, only an insignificant amount of energy is thus available for a single operation of the receiver. Furthermore the energy obtained through the co-operation of the impulses is in the form of an extremely rapid vibration and unsuitable for the operation of ordinary receivers. To overcome these limitations of the two methods mentioned, Tesla reproduces arbitrarily varied or intermittent disturbances or effects; transmits these disturbances through the air to a distant receiving station; utilizes the energy derived from such disturbances at the receiving station to charge a condenser; and uses the accumulated potential so obtained to operate a receiving device.

The apparatus which is employed at the receiving station consists in the combination of a storage d vice included in a circuit; connection points at a d tance from the source of the disturbances and tween which a difference of potential is created such disturbances; a receiving circuit connected wi the storage device; a receiver included in the receiv circuit, and a mechanism for closing the receiv circuit at any desired moment, thereby causi the receiver to be operated by the energy with whic the storage device has been charged.

In another method the energy stored is not, as in the preceding instance, obtained from the energy of the disturbance effect transmitted from a distance, but from an independent source. The method in general consists in charging a storage device with energy from an independent source, controlling the charge of the device by the action of the effects or disturbances transmitted through the natural media, and coincidently using the stored energy for operating a receiver. A condenser is used as the storag means.



The invisible radiations of the spectrum and of vacuum tubes are generally considered to be vibrations of extremely small wave length. These radiations possess the property of charging and discharging conductors of electricity, the discharge being particularly noticeable when the conductor upon which the rays impinge is negatively electrified. is usually held that these radiations ionize or render conducting the atmosphere through which they are propagated. Tesla's own experiments lead him, however, to conclusions more in accord with the theory he has already advanced, in which he holds that sources of such radiant energy throw off with great velocity minute particles of matter which are strongly electrified, and therefore capable of charging an electrical conductor, or, even if not so, of discharging an electrified conductor either by carrying off bodily its charge or otherwise. Tesla has taken out a patent based upon a discovery which he has made, that when rays or radiations of this kind are permitted to fall upon an insulated conducting body connected with one of the terminals of a condenser, while the other terminal is made by independent means to receive or carry away electricity, a current flows into the condenser so long as the insulated body is exposed to the rays. Under certain conditions an indefinite ac-

cumulation of electrical energy takes place. This energy after a suitable time interval, during which the rays are allowed to act, may manifest itself in a powerful discharge, which can be utilized for the operation or control of mechanical or electrical devices or rendered useful in many other ways. The radiant energy is directed upon an elevated conductor, connected with one of the armatures of the condenser, positively electrified by the invisible radiations. The electricity is carried off from the other armature by connecting it with the ground. The accumulated energy is discharged through a suitable receiver.

TESLA'S METHOD OF INCREASING THE INTENSITY OF ELECTRICAL OSCILLATIONS.†

Nikola Tesla still continues his interesting experiments with electrical vibrations, upon which he has been engaged for the last 10 years. Among the patents issued from the United States Patent Office on October 22nd was one granted to him for "Means for Increasing the Intensity of Electrical Oscillations." The patent is numbered 685,012, and the application for it was filed March 21, 1900, and renewed July 3, 1901. Mr. Tesla describes his invention in the following language:—In many scientific and practical uses of electrical impulses or oscillations—as, for example, in systems of transmitting intelligence to distant points—it is of great importance to intensify as much as possible the current impulses or vibrations which are produced in the circuits of the transmitting and receiving instruments, particularly of the latter. It is well known that when electrical impulses are impressed upon a circuit adapted to oscillate freely the intensity of the oscillations developed in the same is dependent on the magnitude of its physical constants and the relation of the periods of the impressed and of the free oscillations. For the attainment of the best result it is necessary that the periods of the impressed should be the same as that of the free oscillations, under which conditions the intensity of the latter is greatest and chiefly dependent on the inductance and resistance of the circuit, being directly proportionate to the former and inversely to the latter. In order, therefore, to intensify the impulses or oscillations excited in the circuit—in other words, to produce the greatest rise of current or electrical pressure in the same—it is desirable to make its inductance as large and its resistance as small as practicable. Having this end in view I have devised and used conductors of special forms and of relatively very large cross-section; but I have fouud that limitations exist in regard to the increase of the inductance as well as to the diminution of the resistance. This will be understood when it is borne in mind that the resonant rise of current or pressure in a freely oscillating circuit is proportionate to the frequency of the impulses, and that a large inductance in general involves a slow vibration. On the other hand, an increase of the section of the conductor with the object of reducing its resistance is, beyond a certain limit, of little or no value, principally because electrical oscillations, particularly those of high frequency, pass mainly through the superficial conducting layers, and, while it is true that this drawback may be overcome in a measure by the employment of thin ribbons, tubes, or standard cables, yet in practice other disadvantages arise which often more than offset the gain. It is a well-established fact that as the temperature of a metallic conductor rises its electrical resistance increases, and, in recognition of this, constructors of commercial electrical apparatus have heretofore resorted to many expedients for preventing the coils and other parts of the same from becoming heated when in use, but merely with a view to economising energy and reducing the cost of construction and operation of the apparatus.

Now, I have discovered that when a circuit adapted to vibrate freely is maintained at a low temperature the oscillations excited in the same are to an extraordinary degree magnified and prolonged, and I am thus enabled to produce many valuable results which have heretofore been wholly impracticable. Briefly stated, then, my invention consists in producing a great increase in the intensity and duration of the oscillations excited in a freely vibrating or resonating circuit by maintaining the same at a low temperature. Ordinarily, in commercial apparatus such provision is made only with the object of preventing wasteful heating, and in any event its influence upon the intensity of the oscillations is very slight and practically negligible, for, as a rule, impulses of arbitrary frequency are impressed upon a circuit, irrespective of its own free vibrations, and a resonant rise is expressly avoided. My invention, it will be understood, does not primarily contemplate the saving of energy, but aims at the attainment of a distinctly novel and valuable result—that is, the increase to the greatest practicable degree of the intensity and duration of free oscillations. It may be usefully applied in all cases when this special object is sought, but offers exceptional advantages in those instances in which the freely oscillating discharges of a condenser are utilised. The best and most convenient manner of carrying out the invention of which I am now aware is to surround the freely vibrating circuit or conductor, which is to be maintained at a low temperature, with a suitable cooling medium, which may be any kind of freezing mixture or agent, such as liquid air, and, in order to derive the fullest benefit from the improvement, the circuit should be primarily constructed so as to have the greatest possible self-induction and the smallest practicable resistance, and other rules of construction which are now recognised should be observed. For example, when in a system of transmission of energy for any purpose through the natural media the transmitting and receiving conductors are connected to earth and to an insulated terminal respectively, the lengths of these conductors should be one-quarter of the wave length of the disturbance propagated through them.

In the accompanying drawing I have shown graphically a disposition of apparatus which may be used in applying practically my invention.

The drawing illustrates in perspective two devices, either of which may be the transmitter, while the other is the receiver. In each there is a coil of few turns and low resistance, designated in one by A and in the other by A'. The former coil, supposed to be forming part of the transmitter, is to be connected with a suitable source of current, while the latter is to be included in circuit with a receiving device.

* Whenever oil is used as a filling for transformer cases the greatest care must be taken to see that it is perfectly free from traces of water; moreover, an oil must be selected whose "critical temperature" is over 80°C., and at the same time the maximum temperature rise of the transformer should be kept well within the above-mentioned limit of 45°C.

† From the *Western Electrician*.

In inductive relation to said coils in each instrument is a flat, spirally-wound coil, B or B′, one terminal of which is shown as connected to a ground plate, C, while the other, leading from the centre, is adapted to be connected to an insulated terminal, which is generally maintained at an elevation in the air. The coils BB′ are placed in insulating receptacles, D, which contain the freezing agent, and around which the coils A and A′ are wound.

Coils in the form of a flat spiral, such as those described, are eminently suited for the production of free oscillations, but obviously conductors or circuits of any other form may be used if desired.

From the foregoing the operation of the apparatus will now be readily understood. Assume, first, as the simplest case, that upon the coil A of the transmitter impulses or oscillations of an arbitrary frequency, and irrespective of its own free vibrations, are impressed. Corresponding oscillations will then be induced in the circuit B, which, being constructed and adjusted, as before indicated, so as to vibrate at the same rate, will greatly magnify them, the increase being directly proportionate to the product of the frequency of the oscillations and the inductance of circuit, B, and inversely to the resistance of the latter. Other conditions remaining the same, the intensity of the oscillations in the resonating circuit B will be increased in the same proportion as its resistance is reduced. Very often, however, the conditions may be such that the gain sought is not realised directly by diminishing the resistance of the circuit. In such cases the skilled expert who applies the invention will turn to advantage the reduction of resistance by using a correspondingly longer conductor, thus securing a much greater self-induction, and under all circumstances he will determine the dimensions of the circuit, so as to get the greatest value of the ratio of its inductance as to its resistance, which determines the intensity of the free oscillations. The vibrations of coil B, greatly strengthened, spread to a distance, and on reaching the tuned receiving conductor B′ excite corresponding oscillations in the same, which, for similar reasons, are intensified, with the result of inducing correspondingly stronger currents or oscillations in circuit A′, including the receiving device. When, as may be the case in the transmission of intelligible signals, the circuit A is periodically closed and opened, the effect upon the receiver is heightened in the manner above described, not only because the impulses in the coils B and B′ are strengthened, but also on account of their persistence through a longer interval of time. The advantages offered by the invention are still more fully realised when the circuit A of the transmitter, instead of having impulses of an arbitrary frequency impressed upon it, is itself permitted to vibrate at its own rate, and more particularly so if it be energised by the freely oscillating high-frequency discharges of a condenser. In such a case the cooling of the conductor A, which may be effected in any suitable manner, results in an extraordinary magnification of the oscillation in the resonating circuit B, which I attribute to the increased intensity as well as greater number of the high-frequency oscillations obtained in the circuit A. The receiving coil B′ is energised stronger in proportion, and induces currents of greater intensity in the circuit A′. It is evident from the above that the greater the number of the freely vibrating circuits which alternately receive and transmit energy from one to another the greater, relatively, will be the gain secured by applying my invention.

TESLA'S WIRELESS TELEGRAPH.

Absolutely Private. Absolutely Original. Working to Great Distances.

Nikola Tesla was asked in his laboratory yesterday afternoon about a report touching his immediate intentions as to the transmission of wireless messages, which the inventor pronounced to be a mistake. Mr. Tesla said that his plans were made up long ago, but that he was not in a position to speak of them as yet. He was asked about the progress of his work and he replied:

"Since THE SUN made the first announcement of my undertaking, the work has been steadily progressing. Some delays have of course occurred, but they have been only for the better. And I am more confident than ever that when it is completed I shall give to the world as the first result of my labors in the transmission of power without wires to great distances, a system of telegraphy capable of infinite expansion, and securing the absolute privacy of the messages. I shall shortly make known a novel principle which will to a large degree remove the popular belief that it is impossible to attain that degree of secrecy which is practicable with cables."

When Mr. Tesla was asked whether there was any similarity between his own and other systems he smiled:

"I respect rigorously the rights of others," he said, "and when I give my system to the world I shall ask the entire technical profession to point to any feature of my system—the transmitter, the receiver, the means and methods of recording, the means and methods of producing the requisite electrical energy, and the means and methods of securing absolute privacy and non-interference—which is not of my own creation. I admire skill and enterprise, and my best wishes for success accompany those who sell ready made shoes; but I myself prefer not to use them. They are cheap, but they raise corns and bunions."

The Tesla patents in connection with instruments and principles involved in the transmission of wireless messages, or wireless electrical energy, date from 1896 and 1897.

The New York Sun January 23, 1902

TESLA CURE FOR CONSUMPTION.

High Frequency Currents Used at the Brompton Hospital.

Special Cable Despatch to THE SUN.

LONDON, Jan. 22.—Dr. Symes-Thomson, consulting physician at the Hospital for Consumption, Brompton, in a lecture delivered here, spoke hopefully of the experiments which are being carried on at the hospital in the treatment of phthisis by means of Tesla's high frequency currents and the injection into the veins of a chemical substance that is fatal to the bacilli.

He quoted statistics showing that the deaths from tubercular maladies in London had decreased 55 per cent. in forty years, and predicted that such diseases would be extinct within a century.

The Brooklyn Eagle February 7, 1902

INVENTOR TESLA'S PLANT NEARING COMPLETION.

Buildings at Wardencliff to Be Used in Developing His Electrical Discoveries.

SINKING A VERY DEEP WELL.

A Big Tower 100 Feet in Diameter and Over 200 Feet High—Power House and Dynamos.

(Special to the Eagle.)

Wardenclyffe, L. I., February 8—Work on the buildings to be used by Electrician Tesla in the development of his electrical discoveries, is progressing rapidly. The power house is completed and the foundations of the big tower have been laid, though the cold weather somewhat retarded the masonry work.

The working room, or tower, which will be the foundation for Mr. Tesla's across-the-world flashes, will be octagonal in shape and will be 210 feet high, 100 feet in diameter at the base, narrowing down to 80 feet in diameter at the top. It will be constructed chiefly of wood, though the builders say that fifty tons of iron and steel and 50,000 bolts of various sizes are used in its construction.

Inside the big tower a well 120 feet deep has been sunk, the well being 12 feet square, cased its entire depth with 8 inch timbers, which will be finished off with brick and cement. A staircase, which will lead down into the well, is nearly completed.

Transversely across the bottom of the well will be a series of four tunnels, each to be 100 feet long, and a force of workmen has begun work on these subterranean passages.

The power house is constructed of pressed brick, and is 100 feet square. In it are a boiler room, engine and dynamo room, machine shop and laboratory. The Westinghouse Company furnished the electrical equipment, boilers, engines and dynamos Only the finishing touches are needed on the electrical equipment to make it available and Mr. Tesla promises to begin active operations very soon.

The New York Herald March 25, 1902

NICOLA TESLA REPLIES TO PROFESSOR SLABY

Wireless Transmission of Energy Across the Ocean Will Be of Commercial Value, He Delares.

Mr. Nicola Tesla was asked yesterday for his views regarding the HERALD'S despatch from Professor Slaby on wiresless telegraphy, and he said:—

"I have read Professor Slaby's statement with interest, and I may add that I have kept in touch with his efforts in Hertzian, or 'spark,' telegraphy, as he calls it, for some time past. He has undoubtedly made most valuable contributions to the literature of the subject. He is also an appreciative worker, acknowledging freely the merit of every one, as a purely scientific man always should do.

"While I do not believe that wireless messages over the sea will be as cheap as some enterprising people have asserted of late, still I cannot quite share Professor Slaby's opinion in regard to wireless transmission of energy across the Atlantic. I began nearly two years ago the design and instalment of power plants for commercial use, with the fullest confidence of success, basing my assurance on exact tests and measurements, which admit of no doubt.

"This work was commenced only after I had completely mastered the problem of insuring the absolute privacy of mesages, and inasmuch as I have received in this undertaking the most generous help, I would be unfortunate indeed if my expectations were not to be fully realized. I hope, however, that the transmission of messages without wires is only the first and comparatively insignificant phase of a great revolution which will be wrought by the transmission of vast quantities of energy for industrial purposes to the most distant points on the globe without wires."

TESLA'S WORK AND MARCONI'S

THE FORMER IS THE "FATHER OF WIRELESS TELEGRAPHY."

Lecture in Which Tesla in 1893 Described the Idea Which Marconi Subsequently Demonstrated Practically — Tesla's Theories Followed by Marconi.

Prof. A. Slaby, inventor of the process of wireless telegraphy which the German Emperor has lately ordered to be used by all German warships, which is known as the Slaby-Arco system, and, in an interview in Berlin, given to Nikola Tesla the credit for making possible all the systems of wireless telegraphy now known.

Prof. Slaby refers to Mr. Tesla as the "father of wireless telegraphy," according to the published reports of his interview, and says that Tesla first explained and worked out in his book "Inventions and Researches," published in 1894, the theory which thereafter Marconi was the first to demonstrate practically. While he gives Marconi the credit for the demonstration Prof. Slaby ascribes the origin of wireless telegraphy to the New York inventor.

Probably few people outside of those interested in technical studies have read this first announcement of the theory and of the outline of a process for carrying it out that gave to the world the system of communication now in daily use on the seas. Indeed few know that Tesla promulgated it years before the first wireless message was sent.

The book referred to by Prof. Slaby as published in 1894 was really a republication of the facts and speculations put forth by Mr. Tesla in a lecture delivered before the National Electric Light Association at St. Louis at its sixteenth convention which was in session from Feb. 28 to March 3, 1893.

The lecture was given at a special evening session of the convention, and was entitled "Light and Other High Frequency Phenomena." It was published in the same year in the proceedings of the convention by order of the Executive Committee of the association.

Mr. Tesla had spoken at length upon phenomena produced by electrostatic force, and after devoting some attention to electrical resonance he said:

"In connection with resonance effects and the problems of transmission of energy over a single conductor, which was previously considered, I would say a few words on a subject which constantly fills my thoughts, and which concerns the welfare of all.

"I mean the transmission of intelligible signals, or, perhaps, even power, to any distance without the use of wires.

"I am becoming daily more convinced of the practicability of the scheme; and though I know full well that the great majority of scientific men will not believe that such results can be practically and immediately realized, yet I think that all consider the developments in recent years by a number of workers to have been such as to encourage thoughtful and experiment in this direction.

"My conviction has grown so strong that I no longer look upon this plan of energy or intelligence transmission as a mere theoretical possibility, but as a serious problem in electrical engineering, which must be carried out some day.

"The idea of transmitting intelligence without wires is the natural outcome of the most recent results of electrical investigations. Some enthusiasts have expressed their belief that telephony to any distance by induction through the air is possible. I cannot stretch my imagination so far, but I do firmly believe that it is practicable to disturb, by means of powerful machines, the electro-static condition of the earth, and thus transmit intelligible signals, and, perhaps, power.

"In fact, what is there against the carrying out of such a scheme? We now know that electrical vibration may be transmitted through a single conductor. Why, then, not try to avail ourselves of the earth for this purpose? We need not be frightened by the idea of distance.

"To the weary wanderer counting the mile posts, the earth may appear very large; but to that happiest of all men, the astronomer, who gazes at the heavens, and by their standard judges the magnitude of our globe, it appears very small.

"And so I think it must seem to the electrician; for when he considers the speed with which an electric disturbance is propagated through the earth all his ideas of distance must completely vanish.

"A point of great importance would be first to know what is the capacity of the earth, and what charge does it contain if electrified? Though we have no positive evidence of a charged body existing in space without other oppositely electrified bodies being near, there is a fair probability that the earth is such a body, for by whatever process it was separated from other bodies—and this is the accepted view of its origin—it must have retained a charge, as occurs in all processes of mechanical separation.

"If it be a charged body insulated in space, its capacity should be extremely small—less than one-thousandth of a farad. But the upper strata of the air are conducting, and so, perhaps, is the medium in free space beyond the atmosphere, and these may contain an opposite charge. Then the capacity might be incomparably greater. In any case, it is of the greatest importance to get an idea of what quantity of electricity the earth contains.

"It is difficult to say whether we shall ever acquire this necessary knowledge, but there is hope that we may, and that is by means of electrical resonance. If ever we can ascertain at what period the earth's charge, when disturbed, oscillates with respect to an oppositely electrified system or known circuit, we shall know a fact possibly of the greatest importance to the welfare of the human race.

"I propose to seek for the period by means of an electric oscillator, or a source of alternating electric currents. One of the terminals of the source would be connected to earth, as, for instance, to the city water mains; the other, to an insulated body of large surface.

"It is possible that the outer conducting body of large surface.

"It is possible that the outer conducting air strata of free space contain an opposite charge, and that, together with the earth, they may form a condenser of very large capacity. In such case the period of vibration may be very low, and an alternating dynamo machine might serve for the purpose of the experiment.

"I would then transform the current to a potential as high as it would be found possible, and connect the ends of the high tension secondary to the ground and to the insulated body. By varying the frequency of the currents, and carefully observing the potential of the insulated body, and watching for the disturbance at various neighboring points of the earth's surface, resonance might be detected.

"Should, as the majority of scientific men in all probability believe, the period be extremely small, then a dynamo machine would not do, and a proper electrical oscillator would have to be produced, and perhaps it might not be possible to obtain such rapid vibrations.

"But whether this be possible or not, and whether the earth contains a charge or not, and whatever may be its period of vibration, it certainly is possible—for of this we have daily evidence—to produce some electrical disturbance sufficiently powerful to be perceptible by suitable instruments at any point of the earth's surface."

Mr. Tesla accompanied his lecture with a diagram illustrating his ideas of the wireless telegraphy instrument, which is here reproduced. He said, referring to it:

"Assume that a source of alternating currents, S, be connected, as in the figure, with one of its terminals to earth (convenient to the water mains), and with the other to a body of large surface, P. When the electric oscillation is set up, there will be a movement of electricity in and out of P, and alternating currents will pass through the earth, converging to or diverging from the point C, where the ground connection is made.

"In this manner neighboring points on the earth's surface within a certain radius will be disturbed. But the disturbance will diminish with the distance, and the distance at which the effect will still be perceptible will depend on the quantity of electricity set in motion."

Just here it is interesting to note that Mr. Marconi in an interview with a reporter for THE SUN a few weeks ago said regarding his experiments between Poldhu and Newfoundland that the electric waves produced by his plant at Poldhu "diminished with the increase of distance," but that they "came," that being the important thing. He said also that with greater power he would have better results.

Continuing his lecture Mr. Tesla said, with further reference to the diagram:

"Since the body P is insulated, in order to displace a considerable quantity, the potential of the source must be excessive, since there would be limitations as to the surface of P. The conditions might be adjusted so that the generator or source, S, will set up the same electrical movement as though its circuit were closed.

"Thus it is certainly practicable to impress an electric vibration, at least of a certain low period, upon the earth by means of proper machinery. At what distance such a vibration might be made perceptible can only be conjectured.

"I have on another occasion considered the question how the earth might behave to electric disturbances. There is no doubt that, since in such an experiment the electrical density at the surface could be but extremely small, considering the size of the earth, the air would not act as a very disturbing factor, and there would be not much energy lost through the action of the air, which would be the case if the density were great.

"Theoretically, then, it could not require a great amount of energy to produce a disturbance perceptible at a great distance, or even all over the surface of the globe.

"Now, it is quite certain that at any point within a certain radius of the source S a properly adjusted self-induction and capacity device can be set in action by resonance. But not only can this be done, but another source, S2, similar to S, or any number of such sources, can be set to work in synchronism with the latter, and the vibration thus intensified and spread over a large area, or a flow of electricity produced to or from the source S1, if the same be of opposite phase to the soure S.

"I think that, beyond doubt, it is possible to operate electrical devices in a city, through the ground or pipe system, by resonance from an electrical oscillator located at a central point.

"But the practical solution of this problem would be of incomparably smaller benefit to man than the realization of the scheme of transmitting intelligence, or, perhaps, power, to any distance through the earth or environing medium. If this is at all possible distance does not mean anything.

"Proper apparatus must first be produced, by means of which the problem can be attacked, and I have devoted much thought to this subject. I am firmly convinced that it can be done, and hope that we shall live to see it done."

In March and May, 1900, Mr. Tesla secured patents additional to those which he took out in the years immediately following the first announcement of his theory, these later ones covering developments of his system for the transmission of electrical energy, carrying it far beyond what he had at first suggested, but along the same general lines.

In the specification which forms part of the letters patent dated March 20, 1900, Tesla says, in the formal notice to the public as to what it is that the patent covers:

"I have been led to the discovery of certain highly important and useful facts which have hitherto been unknown. * * * In illustration of these facts a few observations which I have made with apparatus devised for the purposes here contemplated, may be cited.

"For example, a conductor or terminal, to which impulses such as those here considered are supplied, but which is otherwise insulated in space and is remote from any conducting bodies, is surrounded by a luminous flame-like brush or discharge, often covering many hundreds or even as much as several thousands of square feet of surface, this striking phenomenon clearly attesting the high degree of conductivity which the atmosphere attains under the influence of the immense electrical stresses to which it is subjected.

"This influence is, however, not confined to that portion of the atmosphere which is discernible by the eye as luminous and which, as has been the case in some instances actually observed, may fill the space within the spherical or cylindrical envelope of a diameter of sixty feet or more, but reaches out to far remote regions, the insulating qualities of the air being, as I have ascertained, still sensibly impaired at a distance many hundred times that through which the luminous discharge projects from the terminal and in all probability much further.

"The distance extends with the increase of the electro-motive force of the impulses, with the diminution of the density of the atmosphere, with the elevation of the active terminal above the ground, and also, apparently, in a slight measure, with the degree of moisture contained in the air. * * *

"It is, furthermore, a fact that such discharges of extreme tensions, approximating those of lightning, manifest a marked tendency to pass upward away from the ground, which may be due to electrostatic repulsion, or possibly to slight heating and consequent rising of the electrified or ionized air.

"These latter observations make it appear probable that a discharge of this character allowed to escape into the atmosphere from a terminal maintained at a great height will gradually leak through and establish a good conducting path to more elevated and better conducting air strata, a process which possibly takes place in silent lightning discharges frequently witnessed on hot and sultry days.

"It will be apparent to what an extent the conductivity imparted to the air is enhanced by the increase of the electromotive force of the impulses when it is stated that in some instances the area covered by the flame discharge mentioned was enlarged more than sixfold by an augmentation of the electrical pressure amounting scarcely to more than 50 per cent."

It may be noted here that Mr. Marconi, when he went back to Cornwall after his first Newfoundland experiments,' saying that he would increase the power of his plant at Poldhu, made the statement that he had found that an increase of power showed itself multiplied many fold in the greater proportional distance to which his electric waves would carry.

Mr. Tesla's specification in his patent continues:

"By the discovery of these facts and the perfection of means for producing in a safe, economical and thoroughly practicable manner current impulses of the character described it becomes possible to transmit through easily accessible and only moderately rarefied strata of the atmosphere electrical energy not merely in insignificant quantities, such as are suitable for the operation of delicate instruments and like purposes, but also in quantities suitable for industrial uses on a large scale, up to practically any amount, and, according to all the experimental evidence I have obtained, to any terrestrial distance.

"Expressed briefly, my present invention, based upon these discoveries, consists, then, in producing at one point an electrical pressure of such character and magnitude as to cause thereby a current to traverse elevated strata of the air between the point of generation and a distant point at which the energy is to be received and utilized."

After describing his apparatus Mr. Tesla goes on to say:

"While the description here given contemplates chiefly a method and system of energy transmission to a distance through the natural media for industrial purposes, the principles which I have herein disclosed and the apparatus which I have shown will obviously have many other valuable uses—as, for instance, when it is desired to transmit intelligible messages to great distances, or to illuminate upper strata of the air, or to produce, designedly, any useful changes in the condition of the atmosphere, or to manufacture from the gases of the same products, as nitric acid, fertilizing compounds, or the like, by the action of such current impulses, for all of which and for many other valuable purposes they are eminently suitable, and I do not wish to limit myself in this respect."

In his specification in connection with the patent granted May 15, 1900, Tesla says:

"This application is a division of an application filed by me on Sept. 2, 1897, serial number 650,343, entitled 'Systems of Transmission of Electrical Energy,' and is based upon new and useful features and combinations of apparatus shown and described in said application for carrying out the method therein disclosed and claimed.

"The invention which forms the subject of my present application comprises a transmitting coil or conductor, in which electrical currents or oscillations are produced, and which is arranged to cause such currents or oscillations to be propagated by conduction through the natural medium from one point to another remote therefrom and a receiving coil or conductor at such distant point adapted to be excited by the oscillations or currents propagated from the transmitter."

ELECTRICAL ENERGY DIRECT FROM COAL

By J. Wright

THE successful solution of the problem of how to obtain electrical energy direct from coal would go a long way towards revolutionising existing methods in the engineering and scientific world generally, in that a more or less immediate application of enormous resources of power, without the intervention of the present cumbersome boiler, engine, and dynamo, would thus be rendered possible, and solve many of the existing problems which are on the eve of solution, such, for instance, as aerial navigation.

With existing methods for the production of electrical energy on a commercial scale, by means of high-grade boilers and high-efficiency steam engines and dynamos, only about 6 per cent. of the latent energy stored in coal is available at the terminals of the generator. Any system, therefore, which would tend to render this enormous store of energy immediately available, even to the extent of 50 to 60 per cent., would be exceedingly welcome to the engineer and the scientist, and it is with the object of summarising what has already been done in this connection, and in what direction such minor successes point for a final solution, that the following paragraphs have been penned.

One of the earliest discoveries in connection with this problem was that made by an engine-driver named Seghill in 1840, which culminated in the construction of Sir William G. Armstrong's hydro-electric machine. Seghill elicited the fact that steam, issuing, under pressure, from the safety-valve of a boiler, becomes electrified. Armstrong and Pattinson investigated the phenomenon, and found that it was due to the friction of the minute particles of water, or condensed steam, against the walls of the passage providing the exit, and on this fact was based the construction of the historical machine which consisted of a boiler and furnace mounted on four strong glass insulating pillars and provided with the usual gauges and steam dome, from which latter the outlet pipes were led into a species of iron chamber for the purpose of partially condensing the steam prior to its liberation, it being essential to the success of the device that the escaping steam should carry as much moisture as possible. With a similar object in view, and also to increase the frictional resistance offered to its passage, Armstrong constructed a series of wooden nozzles, in passing through which the steam was caused to impinge upon a disc and pass around the edge of the latter. In front of the nozzles was placed a series of metal points forming a collecting comb, against which the particles of condensed vapour were projected. This comb was carried by a second insulating pillar, which served as the positive terminal of the apparatus, whilst the boiler constituted the negative terminal.

With this machine Sir William Armstrong succeeded in producing large quantities of static electricity, which, in discharging from pole to pole, developed sparks from 5 to 6 feet long. The hydro-electric machine proved, however, to be impracticable and inefficient for the production of electrical energy from coal on a commercial scale, and, as a natural consequence, the discovery has never overstepped the boundary imposed by the term "interesting scientific experiment."

A still earlier method of generating an electric current from the heat of combustion of coal is by what are known as thermopiles. As far back as 1822 Seebeck discovered that a current is pro-

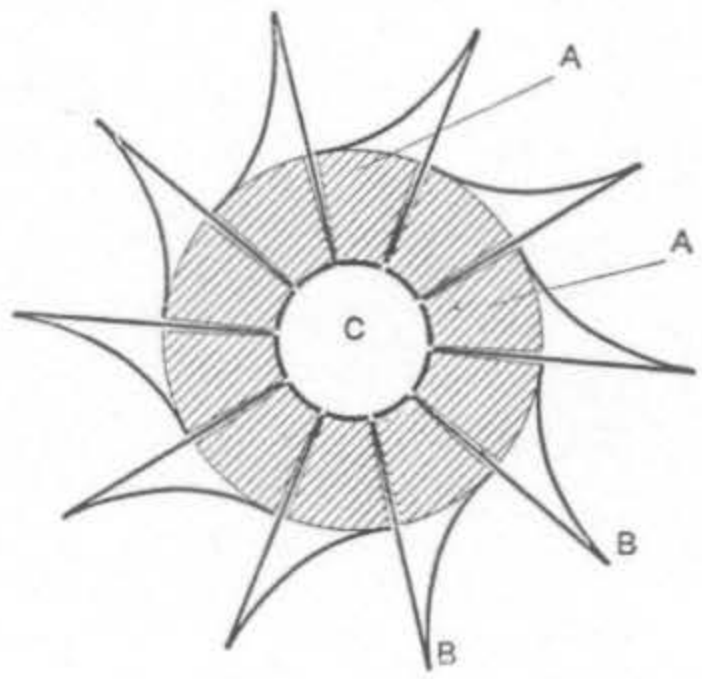


FIG. 1.—CLAMOND'S THERMOPILE

duced in a closed electric circuit by heating the point of contact of two dissimilar metals forming part of that circuit. The electromotive force of the current produced in each couple is very small, and depends upon the two metals selected to form the thermo-electric couple. As the result of his experiments, Seebeck compiled the following table of metals, arranged in their thermo-electric order, each metal being electro-positive to those which follow it in the list:—

(+)	Bismuth	Copper	Silver
	Nickel	Lead	Zinc
	Cobalt	Tin	Iron
	Platinum	Gold	Arsenic
			Antimony (—)

If any two metals be selected from this list, and a good electro-mechanical junction be effected between them, the heating of this junction will produce a flow of current from the electro-positive metal to the electro-negative through the heated junction. Alloys also are available for the production of thermo-electric currents, and Seebeck compiled a second list of metals and their combinations, in thermo-electric order. as follows:—

(+)	Bismuth	3 Bismuth, 1 Lead
	Lead	1 Antimony, 1 Copper
	Tin	1 Antimony, 3 Copper
	1 Bismuth, 3 Tin	1 Antimony, 3 Lead
	1 Bismuth, 3 Lead	1 Antimony, 3 Tin
	Platinum	Steel (cast)
	1 Bismuth, 1 Lead	Steel (rod)
	Gold	3 Bismuth, 1 Tin
	Silver	1 Bismuth, 3 Antimony
	1 Bismuth, 1 Tin	Antimony
	Zinc	1 Antimony, 1 Tin
		3 Antimony, 1 Zinc (—)

Seebeck's discovery led to a number of praiseworthy attempts to apply the thermo-electric principle to the practical generation of electrical energy on a commercial scale. The resulting devices are known as thermopiles, and consist, in the main, of a number of thermo-electric couples, connected together electrically in order to combine their resulting electromotive forces, and constructed physically in such a manner as to facilitate the simultaneous heating of all the junctions from a central source.

One of the earliest thermopiles was that of Markus, constructed in 1864-65, which gained a prize from the Vienna Society for the Promotion of Science. The positive metal was an alloy, consisting of twelve parts of antimony, five parts of zinc, and one part of bismuth, and each electrode consisted of three strips fastened together by screws. The negative electrode, on the other hand, was an alloy consisting of ten parts of copper and six parts of zinc and nickel, and was made in the shape of a rectangular bar. A number of these elements were connected together after the manner of lattice-work, and placed in two rows, sloping together at their apices, and forming a structure not unlike the roof of a house. The ridge of the

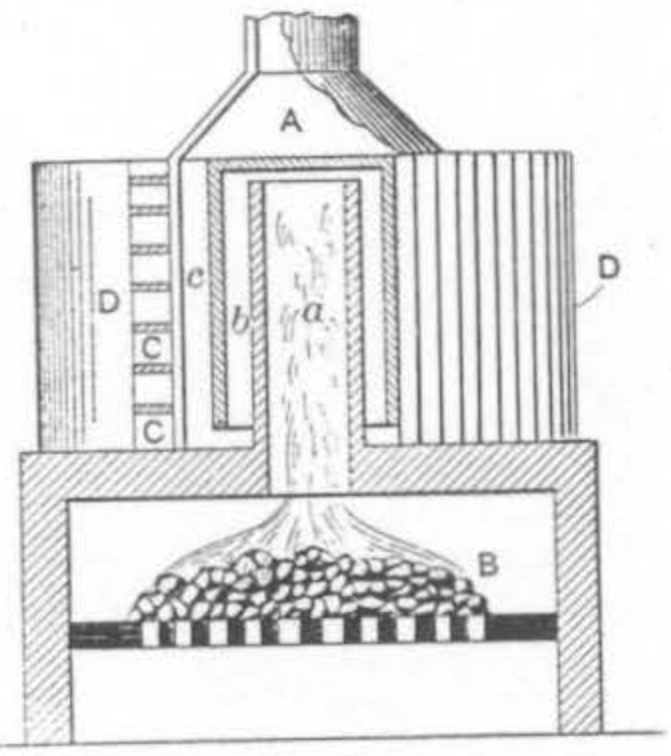

FIG. 2.—AN IMPROVED CLAMOND PILE

"roof" was constituted by an iron bar, to which the junctions were severally attached by means of screws passing through the bar; mica plates and bushings were interposed between the couples

and the bar in order to insulate them, and heat was applied to the junctions through the medium of the iron bar itself, which was supplied with heat from a convenient source. The junctions between neighbouring couples were effected at the lower edges of the slopes and immersed in cold water, in order to make the difference in temperature between the two sets of junctions more marked. The electromotive force of each of these couples was equivalent to one-twentieth of that of a Daniell cell.

Clamond's original thermopile was constructed in cylindrical form, the principle of construction being represented in Fig. 1, which shows a transverse section through one set of couples. *A A* are sector-shaped blocks of an alloy of zinc and antimony, arranged in a circle, and to their inner and outer surfaces are attached the sheet-iron plates, *B B*, these latter being extended, as shown, beyond the normal periphery of the circle, in order to provide an increased surface for the radiation of heat, thereby keeping the outer junctions cool. Several sets of electrodes thus constituted were placed one above the other, and separated by insulating pieces. The central tube or chimney, *C*, thus formed was lined with asbestos cement, and an earthenware tube, pierced with a number of holes to serve as a multiple-jet gas burner, was introduced, and supplied with gas from a convenient source.

In 1879 an improved form of Clamond pile was described by Th. Du Moncel, which was capable of being energised by the heat from a specially constructed coke furnace. It is represented in sectional elevation in Fig. 2, and consists of a zigzag flue *a b c*, made up of three concentric cylinders, communicating with one another at the top and bottom, as shown. The last of these cylinders, *c*, leads into a chimney, *A*, whilst the first receives the hot gases resulting from the combustion of coke in the furnace *B;* the heated gases of combustion are thus compelled to pass three times over the inner surfaces of the cylinders before finding an exit. *C C* are sheet-iron elements arranged immediately outside the cylinder *c*, whilst *D D* are vertical copper plates arranged radially, in order to secure a large surface for cooling the outer junctions by radiation. Cazin records that two such thermopiles, 98 inches high and 39 inches in diameter, each comprising thirty sets of one hundred couples each, were capable of generating current at an electromotive force of 109 volts, and offered an internal resistance of 15.5 ohms. The consumption of coke to achieve this result is stated to have been twenty-two pounds per hour.

Nöe and Hauck also constructed thermopiles on a circular plan; in fact, Clamond's original pile seems to have

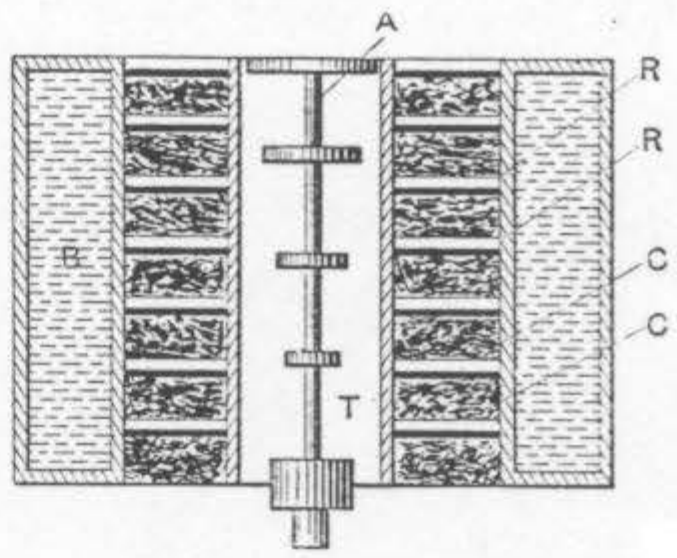

FIG. 3.—COX'S THERMOPILE

set the fashion in this respect, and a very convenient form for heating is thereby procured.

Cox's thermopile is one of the most modern productions in this field, and was, until a short time ago, obtainable in Great Britain, but it is understood that its manufacture has been discontinued. A diagrammatic view of its internal construction is represented in Fig. 3, where *R R* are the thermo-couples, arranged in annular form, and separated from one another by insulating pieces, *C C*. The central tube, *T*, is lined with fireclay and heated by a Bunsen burner, the flame from which is spread outwards against the walls of the tube by a special device, *A*. *B* is a water-jacket, provided with inlet and outlet pipes, and so arranged, immediately outside the outer junctions, as to keep them cool by the circulation of cold water whilst the pile is active. The stock patterns of this pile had electromotive forces of 3, 3.5, 4.5, 5, and 8.5

volts, and were capable of generating 4, 4·5, 3·5, 3·2, and 2.5 ampères, respectively.

There are several other types of thermopile, all of which, however, are similar in principle to the three already described, and which will serve as examples of their kind.

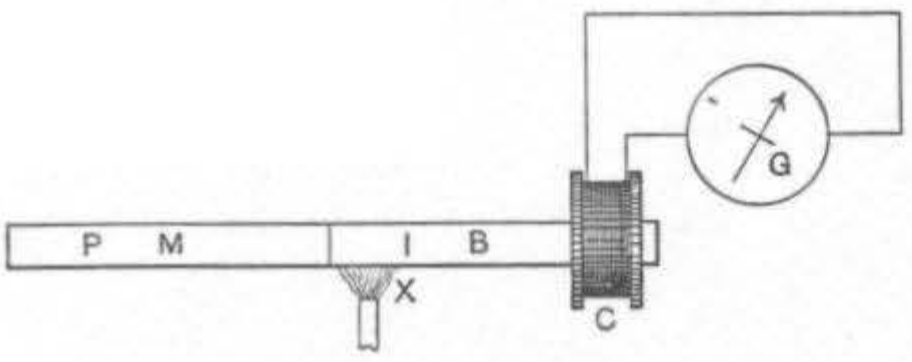

FIG. 4.—THE PRINCIPLE OF TESLA'S PYRO-MAGNETIC GENERATOR

To sum up, the thermopile is an extremely inefficient device for the production of electrical energy from heat, and possesses also several inherent defects, which render it unsuitable for any but a few special requirements. Chief among the drawbacks of this type of generator are, firstly, its necessarily high internal resistance, owing to the fact that the hot and cool junctions must be separated by an appreciable expanse of metal; secondly, the difficulty of preserving, for any length of time, good electrical conductivity at the junction, owing to oxidation and other causes; and thirdly, the extremely rapid depreciation of the pile, owing to the sudden extremes of temperature to which its parts are subjected, and which give rise to consequent expansion and contraction of the metal, tending to loosen all joints, and, in time, prove the destruction of the whole pile.

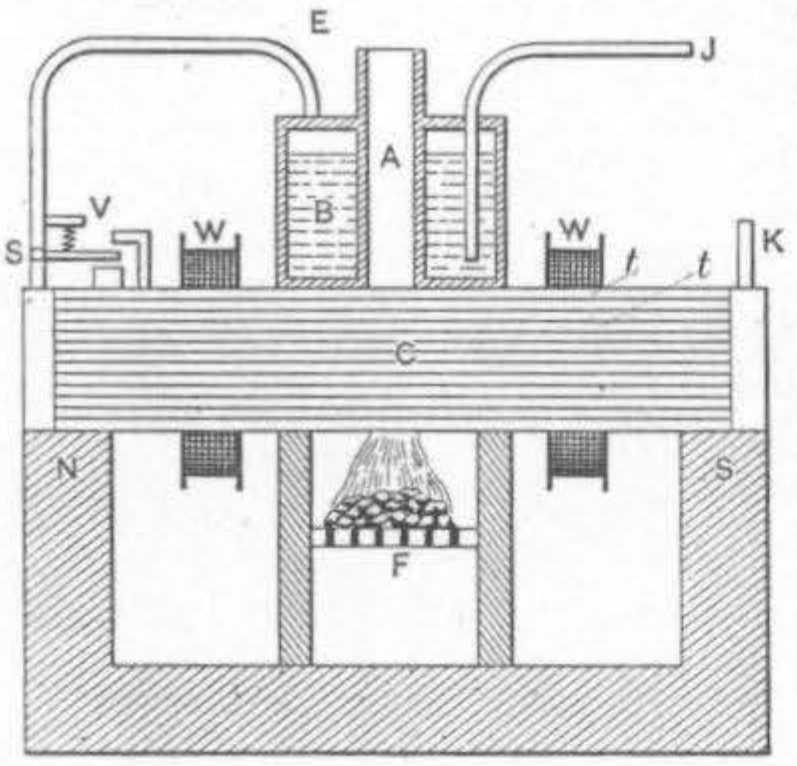

FIG. 5.—TESLA'S GENERATOR

Having thus briefly considered the subject of thermopiles, let us next proceed to discuss what are known as pyro-magnetic generators of electrical energy. At the beginning of the seventeenth century Dr. William Gilbert elicited the fact that natural magnet (loadstone) or a magnetised iron bar, if subjected to a red heat, loses its magnetic properties. On this discovery one or two devices for the generation of electrical energy have been based, and I will first proceed to deal with the work of Nikola Tesla in this direction. Tesla based the design of his pyro-magnetic generator on the above fundamental principle, and also on a second law, which is to the effect that if any conducting body (electrically considered) be subjected to a varying magnetic influence, electrical energy will be developed in that body. These two first principles may be ably demonstrated by a simple experiment, suggested, I believe, by Tesla himself. Referring to Fig. 4, if a permanent bar magnet, *P M*, be placed end on to, and in contact with, an iron bar, *I B*, in such manner as to magnetise the latter by contact, and a coil, *C*, be wound round the outer extremity of *I B*, and connected in circuit with a galvanometer, *G*, as shown, then on heating *I B* at the point *X*, by means of a suitable flame, until it becomes a bright orange-red, indicating a temperature of about 600 degrees C., the magnetism in *I B*

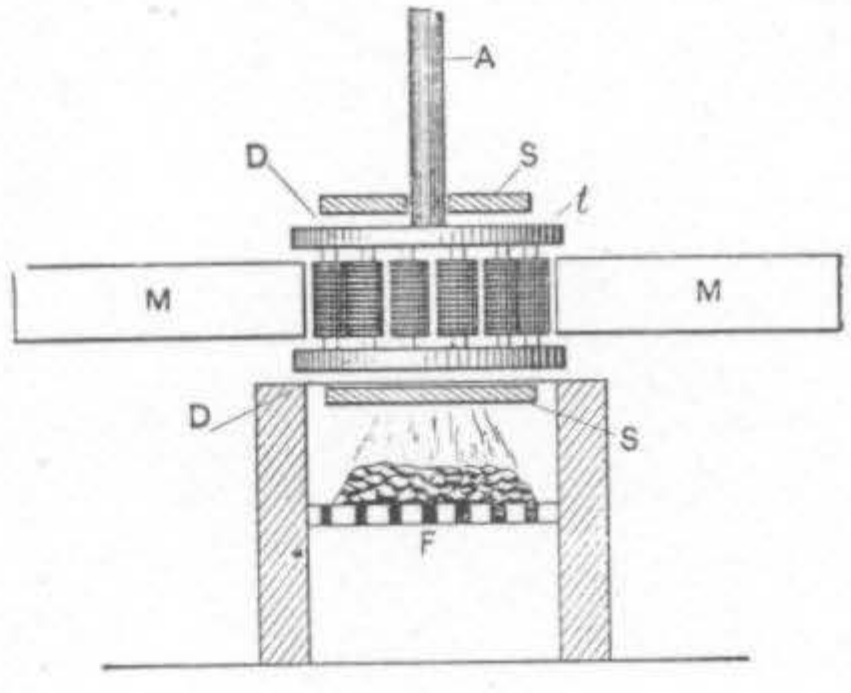

FIG. 6.—EDISON'S GENERATOR

will disappear, and, in its passage, give rise to a current of electricity in the coil, *C*, which will be duly recorded by a deflection of the galvanometer needle. On removing the source of heat and allowing *I B* to cool, its magnetic properties will again return, with the production of a second current in *C*, which, however, will be flowing in an opposite direction to the first, as indicated by the galvanometer needle, which will swing over in the opposite direction.

Tesla's suggestion for the application of this principle in practice is shown in Fig. 5, where *N S* represents a powerful magnet, the poles of which are bridged by a rectangular iron casing *C*, containing a number of iron tubes *t t*, the whole forming an armature or "keeper" to the magnet *N S*. Around the casing are wound coils of insulated wire *W W*, in which the resultant electrical energy is to be generated. The armature passes through the centre of a specially constructed furnace *F*, provided with a chimney *A*, and surmounted by a boiler *B*. A water inlet pipe, *J*, and steam outlet, *E*, are fitted to the boiler the steam outlet being led round to the common entrance of all the tubes, *t*, as shown. An exhaust pipe, *K*, is provided at the opposite extremity of the armature. *V* is a steam valve, actuated by a spring-controlled lever, *S*, which, when the armature is magnetically active, is attracted downwards, and closes the valve. On the centre of the armature becoming heated by the furnace, it loses its magnetism, with a consequent production of electrical energy in the coils *W*, and the release of the lever *S*, which is drawn up by its spring, opening the steam valve, and allowing steam to enter the armature. The steam exercises a cooling effect on the latter, with the result that its magnetism returns, a current is again produced in *W W*, and the steam is automatically cut off, as before, and so the cycle of operations goes on. The main drawback to this and other types of pyro-magnetic generator is their necessarily sluggish action, a perceptible interval being necessary to allow the active portion of the magnetic circuit to assume its extremes of temperature. In 1887 Edison turned his attention to this type of generator, and succeeded in producing a machine of 1500 pounds weight which was capable of developing electrical energy to the extent of 3 H. P. The principle of Edison's generator is represented in Fig. 6, where *M M* are a number of horizontal magnets, arranged radially with their inner poles towards a centre vertical shaft, *A*. On the latter, and so mounted as to revolve with it, is fixed an armature, consisting of a number of vertical iron tubes, *t*, one two-hundredths of an inch in thickness, and mounted, top and bottom, in thick iron discs *D D*. Each of the armature tubes is wound with an insulated wire coil, the ends of which are led to a commutating device (not shown) by which the resulting currents may be rendered unidirectional. *S S* are refractory earthenware or fire-clay screens, arranged, one above, and the other below, a segmental portion of the tubes *t*, so as to screen some of them from the heating effects of the coal furnace *F*. On rotating the armature, those tubes which are open to the furnace lose the magnetism which they receive by induction from the magnets *M*, and a current is generated in the coils surrounding them; on passing over to a position in which they are screened by the segments *S S*, they become cool, with the result that their magnetism returns, and a second current is generated in the coils.

Edison's device possesses several defects; firstly, it is heavy, compared with the output of energy; secondly, its iron tube armature, owing to the fragile construction necessitated, speedily disintegrates; and, thirdly, it can be run only at a slow speed, about 120 revolutions per minute. A generator on a similar principle to the foregoing has also been designed by M. Menges, of Holland, the necessary heat energy being supplied by a number of gas jets.

All the devices so far described for the production of electrical energy from coal have depended on a primary conversion of that latent energy into heat by direct combustion in a furnace. This,

in itself, implies considerable waste, in that many of the elementary bodies contained in the coal are either consumed or pass off in the form of vapour or gas without yielding a proportionate return as heat energy. We must look, therefore, for a more direct conversion than that represented by direct combustion pure and simple.

Volta's valuable discovery at the close of the eighteenth century which resulted in the evolution of the ubiquitous primary battery opened up a wide field for scientific research in connection with the production of electrical energy by chemical action. The element mainly concerned in the production of electrical energy by voltaic action is zinc, and this metal is, unfortunately for the success of the problem, far less plentiful than coal, so that, to contrast the two substances from the point of view of commercial economy in the production of current by known methods, shows a decided balance in favour of coal and the steam engine. With the object of overcoming this drawback many attempts have been made to substitute carbon, the predominant partner in the composition of coal, as the element to undergo combustion in a voltaic cell.

Here we are met by difficulties of a grave nature. Coal *per se* is a poor

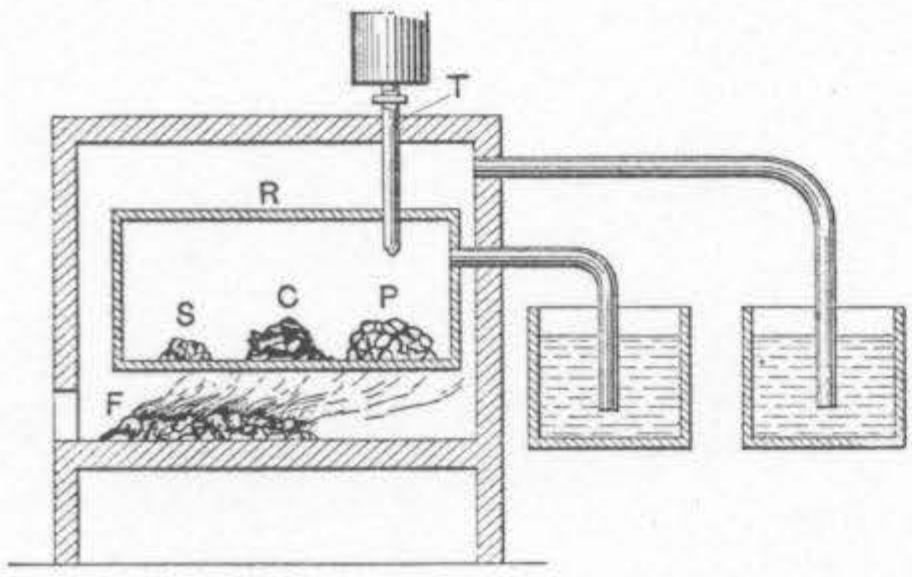

FIG. 7.—REED'S PROCESS

conductor of electricity, but is readily converted into a good one in the shape of coke, which is almost all carbon, and, moreover, gives up valuable by-products in the process of conversion. Then, again, it is essential to the success of a voltaic cell that the positive, or consumed electrode, should be strongly electro-positive, and this, in point of fact, carbon is not, being rather the reverse, and electro-negative to all but a few elements, thus rendering the available range for the selection of a suitable negative very limited in character. To crown all, carbon is insoluble in all ordinary solutions, thus introducing another difficulty,—the selection of an electrolyte.

Despite these various drawbacks, many attempts have been made to employ carbon as a positive electrode in a battery for the generation of electrical energy by voltaic action, and the writer will proceed to deal with one or two of the most noteworthy methods.

C. J. Reed's process, which was first published in 1896, is represented in Fig. 7, where *R* is a retort, mounted upon a suitable furnace, *F*, and containing the separate ingredients *S* and *C*, consisting of sulphur and carbon, respectively. *P* is a small mass of pebbles, over which water is allowed to trickle from a supply tube, *T*. The furnace *F* is fed with sulphur, which, by its combustion, is converted into sulphur dioxide gas; this passes out at the exit flue, and is collected by solution in water, forming sulphurous acid. The heat thus generated causes the sulphur *S* to vapourise, and the vapour, in passing over the mass of heated carbon *C* is converted into bisulphide of carbon. Simultaneously, the heat of the furnace *F* produces steam at the point *P*, and this steam, mingling with the carbon bisulphide vapour, forms sulphuretted hydrogen and carbon dioxide gases. These two mixed gases also pass over into water, which readily dissolves the sulphuretted hydrogen, but the carbon dioxide sparingly,—in such small quantity as to render it negligible. Sulphurous acid and sulphuretted hydrogen solution, thus formed, are placed in a two-compartment vessel, separated by a porous partition which permits diffusion. As electrodes, a carbon plate is placed in each liquid, and the resulting voltaic action produces water and sulphur, giving rise to an electromotive force of about 0.36 volt. Unfortunately, the diffusion, and consequent combination of the two liquids, goes on all the while,

whether the external circuit be open or closed; there is thus considerable waste, and the electromotive force being very low, this arrangement has not proved itself commercially practicable.

Another device, the introduction of which at about the same time created quite a furore in scientific circles, is that of Jacques, and is known as the Jacques cell. It is represented in diagrammatic section by Fig. 8, and consists of a furnace, *F*, over which is mounted an iron retort, *R*, which constitutes the negative electrode of the battery. Placed axially in this retort, but insulated from it by the lid *L*, is the carbon, or positive electrode, *C*, immersed in a mass of fused caustic soda, *S*, contained in the retort *R*, and maintained in a state of fusion by *F*. *P* is an inlet pipe for atmospheric air, under pressure, from a pump, the stream of air being distributed under the lower extremity of the carbon electrode by a perforated head, *H*, similar to the rose of a watering-pot.

The action claimed for this type of generator is as follows:—The oxygen of the air, in the presence of the fused caustic soda, unites with the carbon to form carbon dioxide, which passes off from the retort in the shape of gas, whilst the electrolyte remains unchanged, and can, in consequence, be used indefinitely. An electromotive force of one volt is produced at the terminals of the cell. Theoretically, this action looks very pretty, but the actual reaction which goes on is still, to a certain extent, shrouded in mystery. Suffice it to say that, in practice, carbonate of soda is formed in no inconsiderable quantity, and this, together with other impurities emanating from the carbon, tends to destroy the utility of the caustic soda in course of time. Moreover, an extraneous source of heat, the furnace *F*, is required to work the cell, and also an auxiliary pump for the air supply, both of which items considerably detract from the economical working of the apparatus.

Blumenberg's cell is very similar to the foregoing in its construction and the principle on which it depends for the generation of an electric current. The carbon and containing retort of iron or copper are arranged as in the previous apparatus, whilst the caustic soda is mixed with lime and cryolite. The air-pump of Jacques' cell is rendered unnecessary by the addition of an annular boiler which surrounds the retort and is heated by the same furnace. The steam generated is led into the electrolyte, and, by its decomposition into its constituent elements, hydrogen and oxygen, supplies the place of the air in the former device.

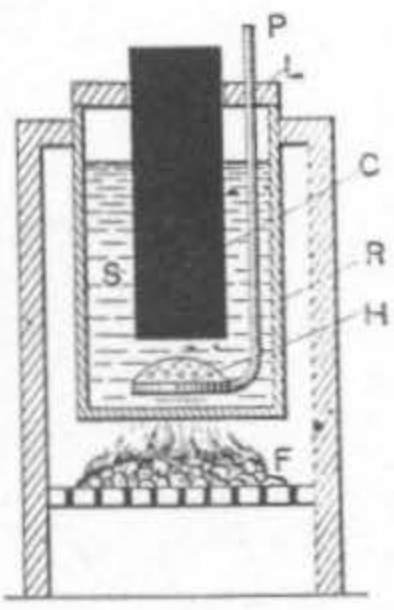

FIG. 8.—THE JACQUES CELL

Whilst on the subject of voltaic action, we must not forget the valuable services rendered by Sir William Grove in his discovery, in 1839, of the "gas battery," and his subsequent indefatigable research in connection with the subject.

As the result of his investigations the following list was compiled, in which each element or gas is electro-positive to all those which follow:—

(+) Metals which decompose water
Hydrogen
Carbonic oxide
Phosphorus
Sulphur
Alcohol
Ether
Olefiant gas
Ethereal oils
Camphor
Metals which do not decompose water
Nitrogen
Carbonic acid
Nitric acid
Oxygen
Peroxides
Iodine
Bromine
Chlorine

The principle of the gas battery consists in substituting gases for the solid electrodes in a voltaic cell, the said gases, by their reaction one upon another and the electrolyte, having the effect of generating a current, available at the terminals of the cell, which latter usually take the form of metallic or carbon plates, immersed partly in the gas and partly in the electrolyte.

One of the most recent attempts to apply the principle of the gas battery to the solution of the problem indicated in

the title of this article was that of Dr. W. Borcher's. His cell at first consisted of an outer glass or stoneware containing vessel, divided into two compartments communicating with each other at the bottom. In this vessel was placed an ammoniacal or acid solution of cuprous chloride; air was supplied to one compartment and carbonic oxide to the other. The electrodes were both of carbon, and yielded only a very weak current when connected.

An improvement on this form was shortly afterwards effected by substituting a copper electrode for the carbon in the carbonic oxide compartment. Coal gas also took the place of carbonic oxide, whilst acid solutions were found to give better results than those of an alkaline nature. By using the last-described form of apparatus, the external compartments being filled with copper turnings, a maximum electromotive force of 0.56 volt was obtained, and, on short circuit, the cell was found to give 0.64 ampère. In a later form of this battery the outer containing vessel was constructed of copper and formed one of the electrodes. The inner cell was of perforated earthenware.

It was estimated that with Dr. Borcher's gas battery at least 27 per cent. of the fuel consumed is converted into electrical energy. Unfortunately, however, recent investigations tend to show that the evolution of a current from this type of cell is due rather to the solution of the valuable copper electrode than the desired carbon or coke, thereby discounting its apparent value in this connection.

The great difficulty met with in the practical application of the gas battery principle consists in the fact that the current-producing capacity of the cell depends on the rate of occlusion of the gases by the electrodes employed. This occlusion, for all practical purposes, requires electrodes of an impracticable area, though it is possible that the preliminary storage of the gases under pressure might effect a saving in this direction. Researches in this field should, therefore, tend to the discovery of an electrode material which is capable of absorbing large volumes of gas, and, at the same time, giving up such gas when required for reaction in a gas battery. The discovery of such a material would greatly extend the scope of the gas battery problem.

Summing up the various data so far available, it is fairly obvious that the final solution of the interesting problem of producing electrical energy directly from coal does not lie with the first three methods, which, as already noted, involve the preliminary generation of heat energy on a wasteful plan. The matter, therefore, lies, so far, with the voltaic cell in which carbon is the consumed electrode and the gas battery, and it is just possible, though hardly probable in the immediate future, and under present known scientific conditions, that either of these methods, or a successful combination of the two, may provide us with a scientific solution. On the other hand, it must be remembered that the apparatus will probably prove cumbersome and costly, so that although the theoretical efficiency might be as high as 70 or even 80 per cent., the great interest on capital outlay would probably be a prohibition to its commercial adoption.

AMERICAN "CAPTAINS OF INDUSTRY."

A RAPID REVIEW OF THE GREAT INDUSTRIAL LEADERS INVITED TO MEET PRINCE HENRY OF PRUSSIA.

BY CARL SNYDER.

WHEN a prince of one of the reigning houses of our continental forebears came to explore somewhat in the Strenuous Land, it was not so much the politicians at Washington, or the Authors' Club, or the National Academy of Sciences, or the leaders of the "New Thought," as it was the captains of industry whom he most desired to meet.

The men of this type who foregathered at the luncheon given to the German visitor, made up an altogether remarkable body. It was probably as representative of American achievement to date as could well have been brought together. It was not exhaustive,—rather by the conspicuous absence of many well-known names did it suggest how imposing our army of achievement has become.

THE CHIEFS.

In the rapid *résumés*, necessarily of exceeding brevity, which follow, more especial attention has been drawn to the list of the invited "captains," comprising, as they do in large part, men not widely known to the public; but their hosts were,—it need hardly be said, a most noteworthy group of men,—the central figures of American finance.

Naturally the name of Mr. J. P. Morgan leads all the rest. He is the unquestioned chief. According to common report, he actually controls more than three billion dollars of capital, and it would not be surprising if these figures were far beneath reality. In a monetary sense he must exert a greater influence than any living man; for to an apparently unlimited amount of capital he unites an energy, an imagination, and an irresistible tenacity of purpose that would mark him in any walk of life. Enterprises, consolidations, reorganizations of a magnitude hitherto unknown in human affairs, seem almost his daily meat and drink. The colossal seems to attract rather than repel him.

The men who served with Mr. Morgan as hosts were chiefly his associates and friends. Mr. Vanderbilt represented what in former times was the largest single interest in the country, the railway holdings of his own family. Morris K. Jesup, railway president and benefactor of science, represented the best type of the American millionaire, those who have endeavored not solely to amass wealth, but to make their riches useful and creditable to their own time. Former Vice-President Morton has had a distinguished career alike as a banker, a diplomat, and as an occupant of important administrative positions. Geo. F. Baker, the veteran president of the First National Bank, stood for the conservative forces of Wall Street. James Stillman might be taken as the banker type *par excellence*, a man whose whole genius seems centered in the successful management of the great institution he directs. Edward D. Adams personated large electric interests, notably the wonderful power development at Niagara Falls, which grows more and more to the proportions of one of the greatest of American enterprises. William Rockefeller came

J. PIERPONT MORGAN. W. K. VANDERBILT. MORRIS K. JESUP. GEORGE F. BAKER. JAMES STILLMAN.

THE AMERICAN INVENTOR.

If the development of its transportation systems has been, perhaps, the most notable fact in American life, the next most noteworthy has certainly been the perfection and utilizing of mechanical devices for the saving of human labor. Excellent examples are to be found in the inventions of Westinghouse, Brown, Church, and a crowd of others.

It was Westinghouse's device of an air brake which made modern railroading possible. Long trains and high speeds without them would be out of question. The Westinghouse brake is now in use all over the world. From the air brake, Mr. Westinghouse turned to electricity, and it is largely to his persevering efforts that the alternating current has come into general use. The lighting of the World's Fair at Chicago was one of his triumphs.

D. H. CHURCH.

Duane H. Church is the great American tool-maker. His business is to build watches. Comparatively few of his eighty million countrymen had ever heard of him until Henry of Prussia came over here, but by his associates he is regarded as a man of almost miraculous powers. His especial achievement has not been so much making fine watches as fine machinery that makes watches. The things he builds perform such a variety of ingenious and accurate functions that they seem almost human in their complicated movements. A single one of his machines will complete a work which before required passing through twenty different hands.

What Duane Church has done to make machines that will do very fine work Alexander Brown, of Cleveland, has done to make machines to do big work. He is one of the men whose inventions in hoisting and ore and iron handling machinery have brought it about that although the rate of wages is the highest, the cost of labor per ton of coal, iron, or steel product in the United States is the lowest in the world.

The inventions and improvements of Edwin Reynolds have been a vital part of the machine practice of this country. He belongs now with the Allis-Chalmers Company, of Milwaukee; but he made his mark with the Corliss Company, of Providence. A great number of inventions in various branches of mechanics testify to his activity, but the Reynolds-Corliss engine is his best-known achievement.

In an old industry it is possible only to improve, but once in a while comes to a man the opportunity to create a wholly new industry. That is what Edward G. Acheson did with carborundum. It was while he was an assistant to Edison in Menlo Park that, partly by accident, he was led to the idea of an artificial abrasive. After a lapse of ten years, systematically he set about the making of the extremely hard compound of carbon and silicon, which he called carborundum. It is some eight times as efficient as emery for grinding, and is now in use in all lines of industry.

Charles M. Hall, whose factory, like Mr. Acheson's, is at Niagara Falls, is the creator of cheap aluminium. The Pittsburg Reduction Company, which owns Mr. Hall's patents, turns out now more than a million dollars' worth of aluminium a year, and it will probably not be long before it will come into very general use. Even now, bulk for bulk, it is as cheap as copper, and improvements in the process cheapen it steadily year by year.

THE ELECTRICIANS.

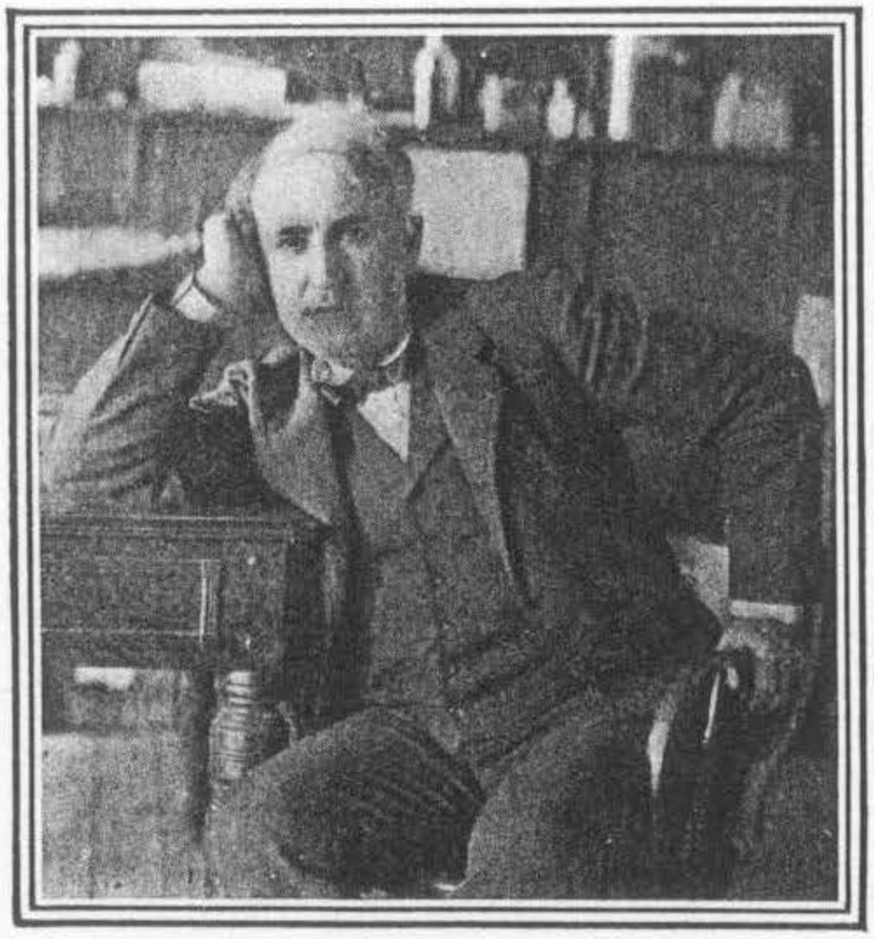
In the field of electricity, the United States has been easily first. Edison, Bell, Tesla, Brush, Thomson,—these are names known in Europe

CHARLES M. HALL. ALEXANDER E. BROWN. EDWARD G. ACHESON. EDWIN REYNOLDS.

MICHAEL I. PUPIN. EDWARD WESTON. ALEXANDER G. BELL. GEORGE GRAY WARD.

hardly less than in America. All of these came to greet the German Prince, and others not less entitled to honorable mention.

In the public mind, at least, the wizard of Menlo Park is almost synonymous with electricity itself. In the multiplicity of his inventions it is hard to distinguish what was the most important. Probably his incandescent lamp should be named, but there is scarcely any department of practical electricity which he has not invaded.



The filing of patents for the telephone on the same day of 1876, by Professor Bell and the late Elisha Gray, will ever remain one of the most remarkable incidents in the history of invention. That two men should have hit upon identically the same principle, destined to be of such immense importance to mankind at the same time, and have completed their work and claimed protection for it at almost the same hour, is one of the most memorable of coincidences.

Nikola Tesla belongs to us only by adoption, but all his notable work was done here. His invention of the induction motor, and his work in the development of long-distance transmission, have had the greatest commercial results, but it is his astonishing achievements with the high-frequency current that have given him so high a standing with scientific men. As yet this work has not found the practical applications Mr. Tesla had hoped for; yet there remain boundless possibilities. Let us hope their creator will live to realize some of them before he gets through.

The work of Elihu Thomson has been far less popular; but it has been solid, aye, and immense. Six hundred inventions in electrical applications stand to his credit. Mr. Thomson's most notable work has been the invention of electrical welding and metal working. The Thomson meter has long been a standard, and hundreds of thousands are made each year. Nearly every electric car utilizes some one or more of his devices; and in addition to all this, he has contributed much to the advance of electrical science.

Charles F. Brush is known best as the father of arc lighting; and the Brush light, in its original form, is still in general use throughout all civilized lands. Like Professor Thomson, he has been decorated by the French Government, and also been the recipient of the Rumford medal. Another pioneer in the electrical field was Edward Weston. English by birth, it was in this country that his improvements in electroplating, deposition, arc and incandescent lighting, dynamos, etc., were done. Since 1886, he has devoted his energies chiefly to the invention and designing of electrical measuring instruments of the highest precision.

The electrical railway owes its beginning and a large part of its development in America to Frank J. Sprague. The first electrically equipped street railway of importance was that which he installed at Richmond, Va. The work was attended with the most discouraging circumstances and experts declared it would never run; but it did, and it marked an epoch in street-railway service. The movable trolley, and most of the other features of electrical traction, are due to his initiative. The equipment of the South

THOMAS A. EDISON.

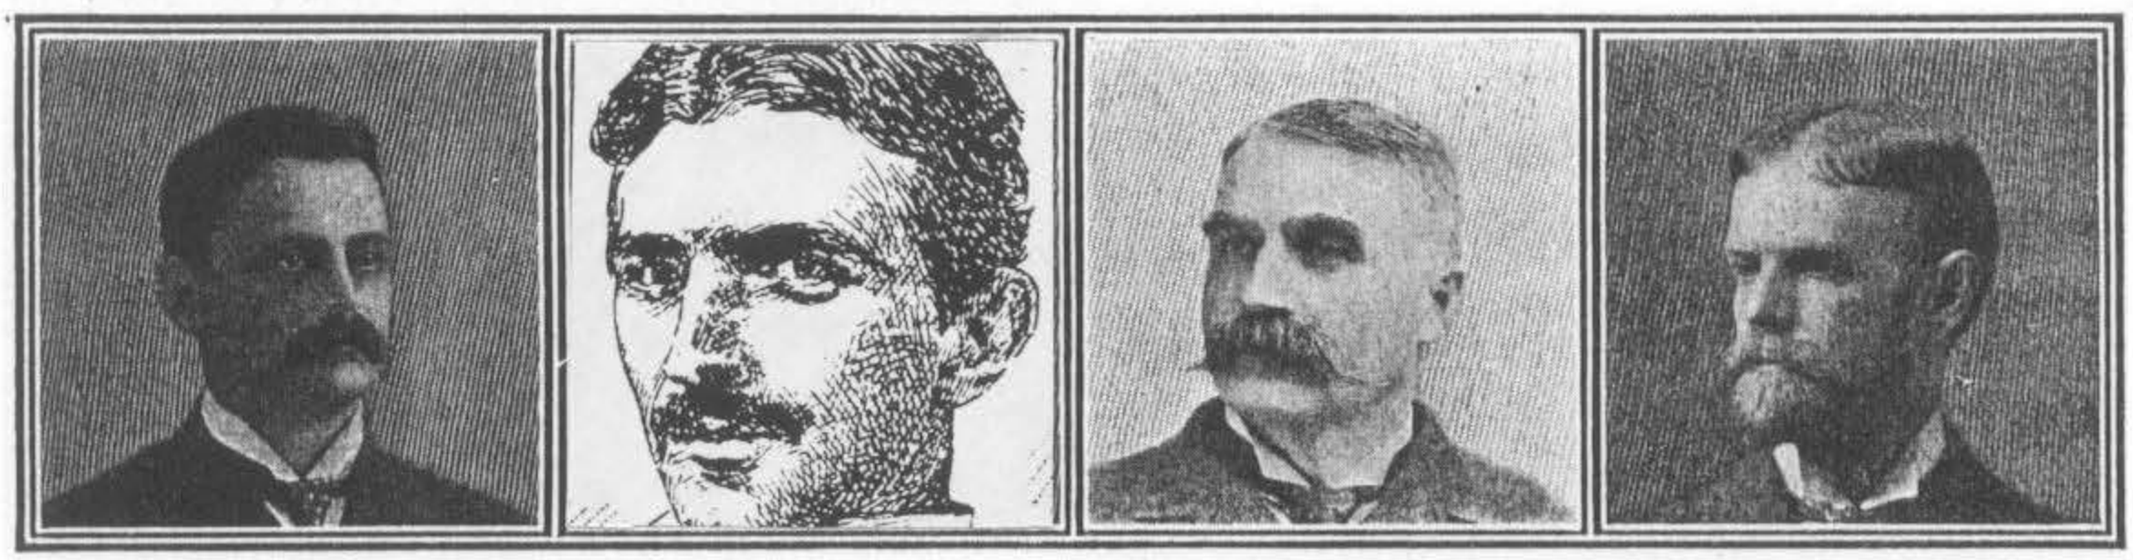
Side Elevated Railroad of Chicago, with what Mr. Sprague calls the "multiple unit" system, was another notable achievement. He likewise built the first large electric locomotive in this country, and has done so many other good things that he might well serve as the type of the aggressive, go-ahead American engineer.

Professor Pupin, of Columbia, is known best for discoveries which may make it possible to telephone around the world. This wonderfully original work is a good example of the practical end which sometimes comes to the most abstract research. It was a splendid work, and its possibilities are immense. Professor Pupin's associate at Columbia, Prof. Francis B. Crocker, has done valuable work in the standardization of electrical apparatus, and it is the uniformity, interchangeability, and other advantages thus secured that have been among the chief factors in placing American electrical manufacture ahead of foreign competitors.

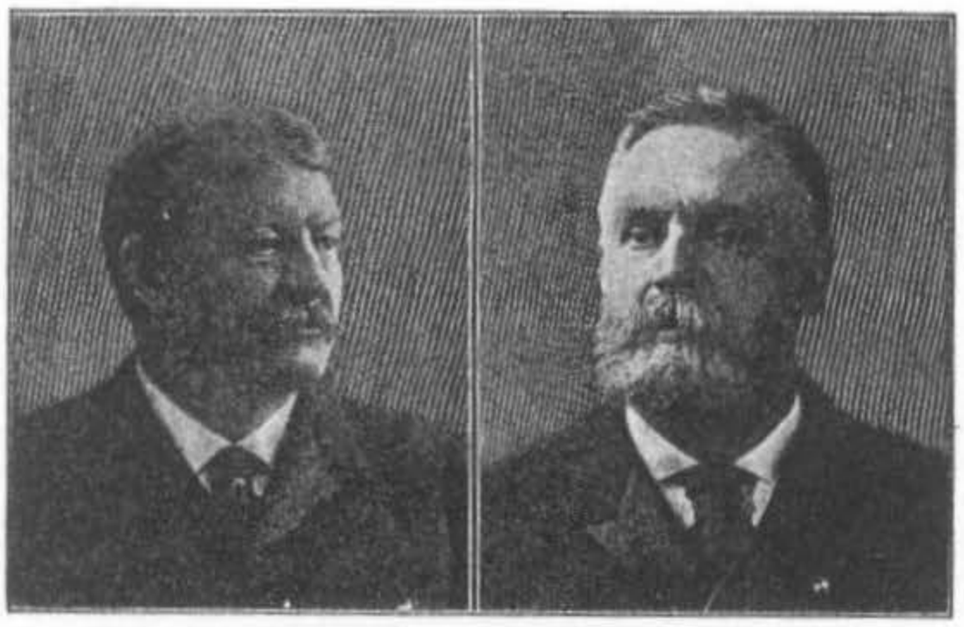
The especial work of Professor Steinmetz, of Schenectady, has been of a technical and theoretical nature. He is the president of the American Institute of Electrical Engineers, and the engineer of the General Electric Company, the largest producers of electrical apparatus in America. His various treatises and papers upon electrical science have given him a high rank among scientific workers. He is now supervising the construction of the new 10,000-horse-power electrical generators for Niagara, by far the largest machines of the kind ever built.

George Gray Ward, the present managing director of the Postal Telegraph and Cable Line, comprising 27,000 miles of land line and 20,000 miles of Atlantic submarine cables, has seen service in many lands. When he began it was considered a great feat to get an answer from a cablegram to London inside half an hour. Now it is frequently done in five minutes. Upon the completion of the direct cable between the United States and Germany a year ago, the German Emperor conferred on Mr. Ward the order of the Royal Prussian Crown.

THE MACHINE MAKERS.



Another group of industrial captains are the great builders of mechanical hands and eyes, and draft horses, and all the other substitutes for human and animal labor which make possible this $13,000,000,000 of manufactured product of the United States each year.



FRANK J. SPRAGUE.

The famous Baldwin locomotive works, founded three quarters of a century ago by Mathias Baldwin, in Philadelphia, was represented by John H. Converse. Its founder would hardly recognize his creation now, so vastly has it grown. When Baldwin died the capacity of the works was a little over one hundred locomotives a year. Now it turns out over a thousand. The Baldwin locomotive of to-day, compared with its prototype of forty years ago, is as a packet steamer f that time to the *Deutschland*. Yet, so perfe is the organization of the works that a locomotive has been ordered, the materials purchased, and the completed work put upon the rails in working order within a space of eight days.

Charles Deering represented the grain-harvesting machines. It is odd to think that mankind should have gone on, in all probability, reaping his fields by hand for thousands of years, and that the methods which were old when the most ancient kings of the Nile lived and ruled should have persisted down to a time within the memory of men yet living, then in half a century have been so profoundly changed. The McCormicks and Deerings have left a deeper impress in the

ELIHU THOMSON. NIKOLA TESLA. CHARLES F. BRUSH. FRANCIS B. CROCKER.

ELIPHALET W. BLISS. ALBERT A. POPE.

life of the world than any Cæsar or Napoleon ; the most distant parts of the earth have felt the effect of their innovations, and the vast wheat fields of the West are in great part their handiwork.

But the typical machine maker of the company was Col. E. W. Bliss, of Brooklyn. His first employment was making gun machinery for the Government. Then he turned his hand to making printing presses. From working paper through a press, he took to the making of all sorts of presses, dies, and special machinery for working sheet metals. He is also president of the United States Projectile Company which makes common shells, shrapnel and armor-piercing projectiles for the United States Government.

Frederick G. Bourne came as the president of the Singer Manufacturing Company. This organization now has 8 factories, making over 800 varieties of sewing machines, with the incredible annual output of 1,200,000 machines and 100,000,000 needles. The company has 75,000 employees under direct control in all parts of the world.

Colonel Pope was the pioneer in the manufacture of the bicycle in this country, and it is largely due to his efforts that American bicycles are sold all over Europe. He deserves well, of his fellow-men, on other accounts, too, for he has been an untiring worker for the betterment of American roads.

Next to the making of machines, their distribution is of prime importance, and Mr. C. A. Moore, of New York, as the representative of the largest manufacturers of machine tools in this country, stood for this especial industry. Nothing can be more gratifying to such of our people as take pride in work well done than to know that American tools, and, more especially, American tool-making machinery, are now conceded to be the best anywhere.

THE IRON AND COAL INTERESTS.

For the easy-going historian, it might suffice to accredit the fact of America's speedily reached supremacy in the production of coal and iron to the existence of an abundantly producing area, comparatively easy of access. One gets a better idea of the fact when one reads of such an undertaking as that of John Markle's construction of the famous Yeddo tunnel in Pennsylvania. That was a tunnel nearly five miles in length, draining drowned-out mines and a huge basin of coal as well. It was an excellent example of American enterprise and the growing tendency in this country to take up difficulties in a large bold way.

JOHN MARKLE.

The nestor of the iron trade is John Fritz. He began life as a blacksmith back in '38, and in his long career has been identified with almost every important thing in the process of making iron and steel which has resulted in an increase of the American product from a quarter of a million tons in 1838 to 16,000,000 tons in 1901. The crowning effort of his life was the conception, the designing, and erection of the great forge and armor plate plant of the Bethlehem Steel Company.

JOHN FRITZ.

George F. Baer, the president of the Reading Railroad, came rather as the representative of the Consolidated Anthracite Coal interests than of his railroad. He is a lawyer, and was for years the confidential legal adviser of Mr. Morgan in Pennsylvania.

Edwin J. Berwind stands for the bituminous coal interests. He has been a pioneer in its export—that is to say, among those who have been shippers of coal to Newcastle.

ELECTRICITY.

XXII. NEW YORK, APRIL 2, 1902. NO. 13.

EDITORIAL NOTES.

A Wireless Telegraphy Wrangle.

At present it looks very much as though there would be a wireless telegraphy war. Prof. Slaby of Berlin, Germany, one of the inventors of the Slaby-Arco system of wireless telegraphy, claims that the Marconi people are doing all in their power to hurt his system in a commercial way. To a representative of the "Herald's" European edition, Prof. Slaby is reported as saying:

"I would like to appeal in behalf of humanity against any undue commercialism in the employment of wireless, or rather the spark, telegraphic system. I am not interested in the commercial exploitation of the Slaby-Arco system now, but purely in its scientific aspect.

"When the Deutschland, with Prince Henry on board, was near land and tried to make connections with its Slaby-Arco system with the Nantucket Station, which is provided with Marconi apparatus, it was impolitely cut off when it was learned at the station that the Deutschland was signaling. Had the steamer been in distress, or if it had been any other ship in distress equipped with a system which the operators of the Marconi Station were not allowed to recognize, such a ship might go to the bottom with all on board, just on account of commercial rivalry, which steps over dead bodies.

"There should be an international congress, and all Governments should oblige stations to receive messages from any ship.

"I do not claim that my system is superior to Mr. Marconi's, but that I arrive at the same results by different construction. Some time ago the Marconi system was offered to the German Government for 2,500,000 marks ($500,000). The Government rejected the offer, and it was this prohibitive price which necessitated the commercial exploitation of the Slaby-Arco system, which is employed not only by the German navy, but by the navies of Sweden and Norway, Denmark and Russia, and is also used in Austria, Belgium, Portugal and Mexico."

Speaking of wireless telegraphy as a rival of the submarine cable Prof. Slaby said:

"Wireless telegraphy will in no event interfere with the cables. It is ridiculous for the shareholders of cable stock to become frightened. When the electric light was introduced holders of gas stock were frightened, but what is the result? Gas is used in overwhelmingly larger quantities than when electricity was introduced.

"The objection to transatlantic telegraphy by ether waves is that such strong currents as Mr. Marconi, for instance, could send from Poldhu interrupt communication over the entire ocean. When two boards are tuned to receive or send messages and a heavy current comes along it destroys communication."

It will be seen that as regards the supplanting of submarine cables by wireless telegraphy Prof. Slaby's opinion agrees with that expressed in these columns some time ago. On the other hand, Nikola Tesla still adheres to his idea of some day sending electric power to all parts of the world without wires, for commenting on Prof. Slaby's statement he says:

"While I do not believe that wireless messages over the sea will be as cheap as some enterprising people have asserted of late, still I cannot quite share Prof. Slaby's opinion in regard to wireless transmission of energy across the Atlantic. I began nearly two years ago the design and installment of power plants for commercial use, with the fullest confidence of success, basing my assurance on exact tests and measurements, which admit of no doubt.

"This work was commenced only after I had completely mastered the problem of insuring the absolute privacy of messages, and inasmuch as I have received in this undertaking the most generous help, I would be unfortunate indeed if my expectations were not to be fully realized. I hope, however, that the transmission of messages without wires is only the first and comparatively insignificant phase of a great revolution which will be wrought by the transmission of vast quantities of energy for industrial purposes to the most distant points on the globe without wires."

The Marconi people on their part say that they are not trying to interfere with Prof. Slaby in any way and deny that the Deutschland was cut off when it tried to communicate with Nantucket by wireless telegraphy.

The following communication on the subject has been given out by the Marconi Company:

"It is contrary to the policy of the Marconi Company to exchange messages with ships equipped with any apparatus but Mr. Marconi and the terms of the agreement under which the New York 'Herald' is using the

Marconi's apparatus at Nantucket prohibit the paper from an exchange of messages with the Slaby-Arco or any other instruments than those of Mr. Marconi.

"Judging, however, from the statements in the 'Herald,' this clause of the agreement was not adhered to. Messages were sent out from Nantucket by the 'Herald's' operators to the Deutschland. These messages were not received, nor, apparently, according to the 'Herald' were any of the Deutschland's messages received at Nantucket."

In the meantime, Rear Admiral Bradford, chief of the Bureau of Equipment, is investigating through his agents abroad all the systems of wireless telegraphy of any merit, with a view of ultimate adoption of one of them for the use of the navy. Thus it is to be presumed that the ships of war of the United States will have the best system, whether that of Marconi or Prof. Slaby.

* * *

THE INVENTOR OF WIRELESS TELEGRAPHY.

ALTHOUGH Signor Marconi is not the inventor, but the skilled exploiter, of telegraphy without wires, everyone must admire the splendid success of his achievement in sending intelligible signals over fifteen hundred miles across the Atlantic. Of ultimate success in establishing regular wireless communication between the two continents there can be no question. The original inventor of the wireless telegraph, Professor Oliver Lodge, had supposed its limits of operation to be a few hundred yards. Signor Marconi two years later gave us reason to think that the range might be extended to a few miles. He pushed his methods till he attained distances of twenty, thirty, even ninety miles. Suddenly he astonishes us with messages to Newfoundland consisting of but a single repeated letter: and lastly he receives from England intelligible records upon a ship that is nearing the American coast.

To the uninitiated this sudden extension of range seemed so remarkable that the news from Newfoundland was received with much incredulity. Those however were not taken by surprise who knew Signor Marconi and were aware of the extensive preparations made at the station at Poldhu, of the powerful engine employed to drive the alternator, of the array of twenty masts over two hundred feet high erected to constitute a transmitting battery for the electric waves. The success was the outcome of a determined plan of campaign. This brilliant result marks however a change in the instrumental methods adopted by Signor Marconi. It may be worth while to attempt in untechnical language to explain wherein the difference lies. The two methods may be distinguished by the names of their respective originators as the method of Lodge and the variety due to Tesla.

In the method of Lodge, the Hertzian waves (or electric waves) generated by a snapping spark between the polished balls of a so-called "oscillator" are received at the distant station upon a receiving apparatus consisting of an extended arm or conductor in combination with a "coherer", a sensitive tube containing minute metal filings, by means of which a local battery is relayed on to a suitable telegraphic instrument, usually a Morse sounder or recorder. The coherer is kept in its sensitive state by receiving gentle vibrations from an automatic "tapper". Every time that a spark is caused to pass in the oscillator a flight of ethereal waves is sent out; and each such flight of waves acting through the coherer at the receiving end delivers a signal in the telegraphic instrument. By careful experimenting and unstinting expenditure on instruments Signor Marconi gradually increased the range of working from the two hundred yards of Lodge's earlier successes up to ninety miles and more. He elongated the extended arm or aerial conductor: he used finer powders in the coherer: he used more sensitive telegraphic receivers; and he perfected under the meaningless name of "jigger" the induction-coils in prior use.

In the apparatus of Tesla torrents of high-frequency sparks are poured out from a secondary induction-coil at a place in the circuit where the discharge is blown aside by a magnetic field or—as in Elihu Thomson's variant—by a blast of air. Every one of such recurring sparks starts its own wave, with effects that are cumulative and therefore capable of being detected at much greater distances. The particular disposition of machinery at Poldhu is understood to be due to Professor Fleming. The precise nature of the detecting instrument used by Signor Marconi in Newfoundland has not been made public: but in the successful communications made in mid-Atlantic a coherer relayed upon a recording telegraph instrument was employed.

When Signor Marconi came to this country five years ago, and conducted experiments under the ægis of the Post Office officials across the Bristol Channel, he was still employing the Righi "oscillator," and the method of Lodge, with a coherer to relay the signals to a telegraph instrument, and an automatic tapper. From the patent which he took out about that time—a document in which he apparently puts himself forward as the inventor of oscillator, coherer, tapper and all—it would appear that the only real point of novelty that he could embody in his claims was that of connecting one end of his coherer to the earth while the other was connected to an elevated and insulated conductor. All else is simply detail or surplusage. It is a very thin claim and has this inherently weak point, that it is quite easy to make a coherer work in some other way—as in fact Lodge did at an earlier, and Professor Slaby at a later date. The man, however, who in 1897 wants to get valid patents must avoid actually claiming the things made public in England in 1894. So it was probably wise of Signor Marconi to avoid making any broad claims to the coherer, the automatic tapper, or any of the features of wireless telegraphy already invented by Lodge. He does not claim them, though audaciously describing them as novelties. Nor do Professor Slaby and Count Arco make any such broad claims in the system of wireless telegraphs which they have independently perfected, and which has been adopted in the German Navy. Both Signor Marconi and Professor Slaby must be content to patent details only—each his own—since neither of them can put himself in the position where Oliver Lodge stands as the original inventor.

Now comes the amusing turn of the whole business. Flushed with his trans-Atlantic success, Signor Marconi, though he has never once dared to contradict the prior claims of Professor Lodge, sends, through some of his underlings, communications to the news agencies whining about the doings of Professor Slaby and Count Arco. His grumbles are duly cabled over from New York and find credence in the English press. But the Slaby-Arco system is as much a lineal descendant of Lodge's earlier work as is Signor Marconi's. Both of them employ Lodge's methods, in that both of them use a coherer to relay Herzian waves upon a telegraphic receiver; and both of them employ an automatic tapper. Eliminate these features, due to Lodge, of coherer-relay and tapper, and both Marconi and Slaby collapse. So Marconi, who uses—without acknowledgment—these devices of Lodge, mouths out denunciations of Slaby, who dares to use the same devices for the same purpose! It is a pretty quarrel. If Signor Marconi imagines that his thin patent claims entitle him to a monopoly of the æther for the purpose of transmitting signals he is much mistaken. His dog-in-the-manger policy toward Professor Slaby is simply silly, and the more so because neither of them can either transmit or receive a single "wireless" message in the United States without infringing the patents of Professor Oliver Lodge. It seems like the irony of fate that Professor Lodge, the well-known Principal of the University of Birmingham, after expounding the principles of wireless telegraphy in London and at Oxford in 1894, should find himself pushed aside, first by the Italian, who by dint of advertisement gains the public ear, and then by the German professor, and yet should actually stand master of the trans-Atlantic situation because he holds the master-patents in the United States. It is said that Lloyds has made an agreement with Signor Marconi for fourteen years. Perhaps Lloyds was not aware of the question as to where the patent rights lie. Signor Marconi may whine as he pleases about other men snatching the rewards from a scientific investigator; that is precisely what he himself has been trying to do for these last four or five years, his victim being the Englishman who was first in the field, and who, if he but knew it, is to-day master of the situation.

SILVANUS P. THOMPSON.

The New York Sun April 7, 1902

TESLA ON LODGE'S PRIORITY.

Less Disputable Than the Importance of His Devices in Wireless Telegraphy.

Nikola Tesla returned yesterday to New York from his plant on Long Island and was seen by a SUN reporter in reference to Prof. Silvanus Thompson's statement that both Marconi and Slaby are indebted to Lodge for his discoveries in wireless telegraphy, rather than to anything that they have originated.

"It is to be regretted that so many eminent men should engage in battle over this matter," Mr. Tesla said, "especially when there is no necessity for it. All the facts in the case may easily be ascertained by going over the records.

"In reference to Hertzian telegraphy, I have been a disinterested onlooker, as I devoted myself to my own system. But I know in a general way that Lodge gave first descriptions of certain devices known as the coherer and the tapper, subsequently used by others. Lodge is a pioneer of great force, and I have myself frequently acknowledged my indebtedness to him in other lines of work.

"Nevertheless, I consider that the published writings of Prof. Slaby on Hertzian apparatus are deserving of the greatest credit, which every one should unhesitatingly accord to him, as he has never failed to acknowledge duly the work of others.

"I disagree with Prof. Thompson on the importance he assigns to the coherer and tapper, as I have exhaustively tested these devices and proved them inadequate for carrying on practically quick telegraphy.

"The coherer is an instrument of wonderful sensitiveness, but there are other devices better suited to use in connection with tuned circuits in all cases in which reliability of action is an important factor.

"Quite apart from that, however, the Hertzian circuits separated from the ground by spark gaps and choking coils, as used by Lodge and others, are for all purposes inoperative, as they permit neither the transmission of effects at considerable distances nor tunings."

TESLA'S WORK AND MARCONI'S.

(From the New York Sun.)

Prof. A. Slaby, inventor of the process of wireless telegraphy which the German Emperor has lately ordered to be used by all German warships, which is known as the Slaby-Arco system, has, in an interview in Berlin, given to Nikola Tesla the credit for making possible all the systems of wireless telegraphy now known.

Prof. Slaby refers to Mr. Tesla as the "father of wireless telegraphy," according to the published reports of his interview, and says that Tesla first explained and worked out in his book "Inventions and Researches," published in 1894, the theory which thereafter Marconi was the first to demonstrate practically. While he gives Marconi the credit for the demonstration, Prof. Slaby ascribes the origin of wireless telegraphy to the New York inventor.

Probably few people outside of those interested in technical studies have read this first announcement of the theory and of the outline of a process for carrying it out that gave to the world the system of communication now in daily use on the seas. Indeed few know that Tesla promulgated it years before the first wireless message was sent.

The book referred to by Prof. Slaby as published in 1894 was really a republication of the facts and speculations put forth by Mr. Tesla in a lecture delivered before the National Electric Light Association at St. Louis at its sixteenth convention which was in session from February 28 to March 3, 1893.

The lecture was given at a special evening session of the convention, and was entitled "Light and Other High Frequency Phenomena." It was published in the same year in the proceedings of the convention by order of the executive committee of the association.

Mr. Tesla had spoken at length upon phenomena produced by electrostatic force, and after devoting some attention to electrical resonance, he said:

"In connection with resonance effects and the problems of transmission of energy over a single conductor, which was previously considered, I would say a few words on a subject which constantly fills my thoughts, and which concerns the welfare of all.

"I mean the transmission of intelligible signals, or perhaps, even power, to any distance without the use of wires.

"I am becoming daily more convinced of the practicability of the scheme, and, though I know full well that the great majority of scientific men will not believe that such results can be practically and immediately realized, yet I think that all consider the developments in recent years by a number of workers to have been such as to encourage thoughtful experiment in this direction.

"My conviction has grown so strong that I no longer look upon this plan of energy or intelligence transmission as a mere theoretical possibility, but as a serious problem in electrical engineering, which must be carried out some day.

"The idea of transmitting intelligence without wires is the natural outcome of the most recent results of electrical investigations. Some enthusiasts have expressed their belief that telephony to any distance by induction through the air is possible. I cannot stretch my imagination so far, but I do firmly believe

that it is practicable to disturb, by means of powerful machines, the electro-static condition of the earth, and thus transmit intelligible signals, and perhaps power.

"In fact, what is there against the carrying out of such a scheme? We now know that electrical vibration may be transmitted through a single conductor. Why, then, not try to avail ourselves of the earth for this purpose? We need not be frightened by the idea of distance.

"To the weary wanderer counting the mile posts, the earth may appear very large, but to that happiest of all men, the astronomer, who gazes at the heavens, and by their standard judges the magnitude of our globe, it appears very small.

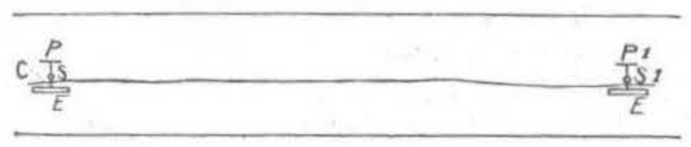
"And so I think it must seem to the electrician; for when he considers the speed with which an electric disturbance is propagated through the earth all his ideas of distance must completely vanish.

"A point of great importance would be first to know what is the capacity of the earth, and what charge does it contain if electrified? Though we have no positive evidence of a charged body existing in space without other oppositely electrified bodies being near, there is a fair probability that the earth is such a body, for, by whatever process it was separated from other bodies—and this is the accepted view of its origin—it must have retained a charge, as occurs in all processes of mechanical separation.

"If it be a charged body insulated in space, its capacity should be extremely small—less than one thousandth of a farad. But the upper strata of the air are conducting, and so, perhaps, is the medium in free space beyond the atmosphere, and these may contain an opposite charge. Then the capacity might be incomparably greater. In any case, it is of the greatest importance to get an idea of what quantity of electricity the earth contains.

"It is difficult to say whether we shall ever acquire this necessary knowledge, but there is hope that we may, and that is by means of electrical resonance. If ever we can ascertain at what period the earth's charge, when disturbed, oscillates with respect to an oppositely electrified system or known circuit, we shall know a fact possibly of the greatest importance to the welfare of the human race.

"I propose to seek for the period by means of an electric oscillator, or a source of alternating electric currents. One of the terminals of the source would be connected to earth, as, for instance, to the city water mains; the other to an insulated body of large surface.



"It is possible that the outer conducting air strata of free space contain an opposite charge, and that, together with the earth, they may form a condenser of very large capacity. In such case the period of vibration may be very low, and an alternating dynamo machine might serve for the purpose of the experiment.

"I would then transform the current to a potential as high as it would be found possible, and connect the ends of the high tension secondary to the ground and to the insulated body. By varying the frequency of the currents, and carefully observing the potential of the insulated body, and watching for the disturbance at various neighboring points of the earth's surface, resonance might be detected.

"Should, as the majority of scientific men in all probability believe, the period be extremely small, then a dynamo machine would not do, and a proper electrical oscillator would have to be produced, and perhaps it might not be possible to obtain such rapid vibrations.

"But whether this be possible or not, and whether the earth contains a charge or not, and whatever may be its period of vibration, it certainly is possible—for of this we have daily evidence—to produce some electrical disturbance sufficiently powerful to be perceptible by suitable instruments at any point of the earth's surface."

Mr. Tesla accompanied his lecture with a diagram illustrating his idea of the wireless telegraphy instrument, which is here reproduced. He said, referring to it:

"Assume that a source of alternating currents, S, be connected, as in the figure, with one of its terminals to earth (convenient to the water mains), and with the other to a body of large surface, P. When the electric oscillation is set up, there will be a movement of electricity in and out of P, and alternating currents will pass through the earth, converging to or diverging from the point C, where the ground connection is made.

"In this manner neighboring points on the earth's surface within a certain radius will be disturbed. But the disturbance will diminish with the distance, and the distance at which the effect will be perceptible will depend on the quantity of electricity set in motion."

Just here it is interesting to note that Mr. Marconi in an interview with a reporter for the "Sun" a few weeks ago said regarding his experiments between Poldhu and Newfoundland that the electric waves produced by his plant at Poldhu "diminished with the increase of distance," but that they "came," that being the important thing. He said also that with greater power he would have better results.

Continuing his lecture Mr. Tesla said, with further reference to the diagram:

"Since the body P is insulated, in order to displace a considerable quantity, the potential of the source must be excessive, since there would be limitations as to the service of P. The conditions might be adjusted so that the generator or source, S, will set up the same electrical movement as though its circuit were closed.

"Thus it is certainly practicable to impress an electric vibration, at least of a certain low period, upon the earth by means of proper machinery. At what distance such a vibration might be made perceptible can only be conjectured.

"I have on another occasion considered the question how the earth might behave to electric disturbances. There is no doubt that, since in such an experiment the electrical density at the surface could be but extremely small, considering the size of the earth, the air would not act as a very disturbing factor, and there would be not much energy lost through the action of the air, which would be the case if the density were great.

"Theoretically, then, it could not require a great amount of energy to produce a disturbance perceptible at a great distance, or even all over the surface of the globe.

"Now, it is quite certain that at any point within a certain radius of the source S a properly adjusted self-induction and capacity device can be set in action by resonance. But not only can this be done, but another source, S2, similar to S, or any number of such sources, can be set to work in synchronism with the latter, and the vibration thus intensified and spread over a large area, or a flow of electricity produced to or from the source S1, if the same be on opposite phase to the source S.

"I think that, beyond doubt, it is possible to operate electrical devices in a city, through the ground or pipe system, by resonance from an electrical oscillator located at a central point.

"But the practical solution of this problem would be of incomparably smaller benefit to man than the realization of the scheme of transmitting intelligence, or perhaps, power, to any distance through the earth or environing medium. If this is at all possible distance does not mean anything.

"Proper apparatus must first be produced by means of which the problem can be attacked, and I have devoted much thought to this subject. I am firmly convinced that it can be done, and hope that we shall live to see it done."

In March and May, 1900, Mr. Tesla secured patents additional to those which he took out in the years immediately following the first announcement of his theory, these later ones covering developments of his system for the transmission of electrical energy, carrying it far beyond what he had at first suggested, but along the same general lines.

In the specification which forms part of the letters patent dated March 20, 1900, Tesla says, in the formal notice to the public as to what it is that the patent covers:

"I have been led to the discovery of certain highly important and useful facts which have hitherto been unknown. . . . In illustration of these facts a few observations which I have made with apparatus devised for the purposes here contemplated, may be cited.

"For example, a conductor or terminal, to which impulses such as those here considered are supplied, but which is otherwise insulated in space, and is remote from any conducting bodies, is surrounded by a luminous flame-like brush or discharge, often covering many hundreds or even as much as several thousands of square feet of surface, this striking phenomenon clearly attesting the high degree of conductivity which the atmosphere attains under the influence of the immense electrical stresses to which it is subjected.

"This influence is, however, not confined to that portion of the atmosphere which is discernible by the eye as luminous and which, as has been the case in some instances actually observed, may fill the space within the spherical or cylindrical envelope of a diameter of sixty feet or more, but reaches out to far remote regions, the insulating qualities of the air being, as I have ascertained, still sensibly impaired at a distance many hundred times that through which the luminous discharge projects from the terminal and in all probability much further.

"It is, furthermore, a fact that such discharges of extreme tensions, approximating those of lightning, manifest a marked tendency to pass upwards away from the ground, which may be due to electrostatic repulsion, or possibly to slight heating and consequent rising of the electrified or ionized air."

It may be noted here that Mr. Marconi,

when he went back to Cornwall after his first Newfoundland experiments, saying that he would increase the power of his plant at Poldhu, made the statement that he had found that an increase of power showed itself multiplied many fold in the greater proportional distance to which his electric waves would carry.

Mr. Tesla's specification in his patent continues:

"By the discovery of these facts and the perfection of means for producing in a safe, economical and thoroughly practicable manner current impulses of the character described it becomes possible to transmit through easily accessible and only moderately rarified strata of the atmosphere electrical energy not merely in insignificant quantities, such as are suitable for the operation of delicate instruments and like purposes, but also in quantities suitable for industrial uses on a large scale, up to practically any amount, and, according to all the experimental evidence I have obtained, to any terrestrial distance.

"Expressed briefly, my present invention, based upon these discoveries, consists, then, in producing at one point an electrical pressure of such character and magnitude as to cause thereby a current to traverse elevated strata of the air between the point of generation and a distant point at which the energy is to be received and utilized."

After describing his apparatus Mr. Tesla goes on to say:

"While the description here given contemplates chiefly a method and system of energy transmission to a distance through the natural media for industrial purposes, the principles which I have herein disclosed, and the apparatus which I have shown, will obviously have many other valuable uses—as, for instance, when it is desired to transmit intelligible messages to great distances, or to illuminate upper strata of the air, or to produce, designedly, any useful changes in the condition of the atmosphere, or to manufacture from the gases of the same products, as nitric acid, fertilizing compounds, or the like, by the action of such current impulses, for all of which and for many other valuable purposes, they are eminently suitable, and I do not wish to limit myself in this respect."

In his specification in connection with the patent granted May 15, 1900, Tesla says:

"This application is a division of an application filed by me on September 2, 1897, serial number 650,343, entitled 'Systems of Transmission of Electrical Energy,' and is based upon new and useful features and combinations of apparatus shown and described in said application for carrying out the method therein disclosed and claimed.

"The invention which forms the subject of my present application comprises a transmitting coil or conductor, in which electrical currents or oscillations are produced, and which is arranged to cause such currents or oscillations to be propagated by conduction through the natural medium from one point to another remote therefrom and a receiving coil or conductor at such distant point adapted to be excited by the oscillations or currents propagated from the transmitter."

TESLA SPLIT-PHASE PATENTS.—The United States Circuit Court of Appeals of the Sixth Ohio District has rendered a decision sustaining the Tesla split-phase patents of Dec. 26, 1893. The decision was on an appeal from the lower circuit court in a suit for the infringement of the above patents as applied to a fan motor. The defence in both cases was that the invention of the above-mentioned patents had been the subject of an earlier patent issued to the same inventor Dec. 3, 1889, on an application filed May 20, 1889. The applications for the first mentioned patents were filed Dec. 8, 1888. The court held that the earlier patent relates to the construction of motors and circuits capable of utilizing the properties of self-induction and the resistance in the circuit, to effect the delivery of alternating currents such as to induce a sustained rotation of the motor. The claims are for special means or apparatus designed to be employed in carrying out the inventor's method of operating his motor as described in the later patents. Since the invention of the specific means covered by these claims, and the generic invention of the later patents were for independent inventions, and neither had been given to the public, the court held that it was competent for the inventor to take out a patent for each; and that in such case it is not material that the taking out of one patent was prior to that of the other. The subject matter of the later patents—that is, the invention covered by them—was not a component part of the former invention, but was an independent invention not necessary to the composition of the first, or included in it.

Tesla Patents Decision.

The United States Circuit Court of the District of Rhode Island handed down an opinion, May 12, sustaining the Tesla patents, in a suit of the Westinghouse Electric Manufacturing Company against the Royal Weaving Company, of Pawtucket, R. I. The suit was on a preliminary injunction against the infringement of certain patents which the court states were the same as those sustained in a suit against the New England Granite Company, the opinion in which suit was reprinted in our columns at the time. The opinion states that the defendant relied principally on a French patent issued to Dumesnil, Aug. 8, 1884, and on a French patent issued to Cabanellas, April 9, 1885. The contention was that these patents disclosed what was not before the courts in the Granite case, namely, that two single-phase synchronous motors could be coupled together, as for example, by having their armatures mounted on the same shaft; and that these two motors might be run each by its own circuit of alternating currents, which might be supplied either by two single-phase generators so mounted on the same shaft as to give currents out of phase with each other; or that a single generator, such as is known in the prior art, and which furnished alternating currents differing in phase, might have been used as the source of supply. The court considers that the above-mentioned patents, if produced in the Granite State case would not have affected the decisions as to the nature and novelty of the Tesla invention and as to the validity of the patents in suit. Referring to the Dumesnil patent, the court considered that to couple two single-phase synchronous motors upon one shaft, displacing the poles of one armature angularly with respect to the other so that one motor expends its maximum effort while the other expends its minimum effort, does not seem to exhibit the Tesla invention as described and claimed in the Tesla patent. Referring to the Cabanellas patent, the court said that this patent, upon many readings, seems to it to be fairly characterized by the complainant's counsel as "expressed in such obscure and indefinite terms as to be hopelessly unintelligible except in a few unimportant particulars," and as requiring an exceptional exercise of the imaginative powers in translating its phrases into electrical diagrams. The opinion further states that the Dumesnil and Cabanellas patents at best were based upon the use of two motors of an old type having the characteristic defects of such motors, and lacking the characteristics of the Tesla motors. Even if two of these motors can assist each other, by so timing their mechanical efforts that one exerts its maximum effect while the other exerts its minimum effect, the court does not find in such a combination of the two machines the invention of Tesla, nor the rotary field which was apparently conceded by the defendant in prior suits to be proper subject matter of controversy in determining the validity of the Tesla patent. The court decides that the question of infringement seems to be substantially determined by the prior decisions. The questions as to whether the defendant may be permitted to continue temporarily the use of the motors now installed, and if so, upon what terms, were reserved by the court.

Philadelphia North American May 18, 1902

TESLA THINKS WIND POWER SHOULD BE USED MORE NOW

By Nikola Tesla

The power of the wind has been overlooked. Some day it will be forcibly brought to the position it deserves through the need of a substitute for the present method of generating power. Given a good breeze, I have estimated that there is as much as half a horse-power to every square fooot of area exposed. Imagine what energy is left unused with all this force at hand.

The contrivance that has been at the disposal of mankind from all time, the windmill, is now seen in the rural districts only. The popular mind cannot grasp the power there is in the wind. Many a deluded inventor has spent years of his life in endeavoring to harness the tides, and some have even proposed to compress air by tide or wave power for supplying energy, never understanding the signs of the old windmill on the hill as it sorrowfully waves its arms about and bids them stop.

The fact is that the wave or tide motor would have but small chance of competing commercially with the windmill.
which is by far the better machine, allowing a much greater amount of energy to be obtained in a simpler way.

Wind power has been in all times of inestimable value to man, if for nothing else than for enabling him to cross the seas, and it is even now a very important factor in transportation. But there are limitations in this simple method of utilizing the sun's energy. The machines are large for a given output and the power is intermittent, thus necessitating a storage of energy and increasing the cost of the plant. But there is no question as to its usefulness as a substitute for the energy derived from fuel, and the fact that this power is literally as free as air makes it a wonderful factor in the future of the world of industry.

Apart from the views expressed by Lord Kelvin regarding the future, when the coal supply shall have been exhausted, there is need of more attention being paid to it in the present day.

The man who cannot afford to have a furnace in his house may have a windmill on the roof. In this labor-saving age it is astonishing that farmers are the only citizens who call the wind their friend. Dwellers in cities toil up and down stairs hauling and carrying, while above them is a good-natured giant who can do all this work for them if they will but force him into service. Why wait for the coal supply of the earth to be exhausted before enlisting the aid of this vast aerial force?

The power to run elevators, pump water to roof tanks, cool houses in the summer and heat them in the winter is above us, at any one's beck and call.

A little ingenuity will enable any householder to harness the wind and leave it to do the work that he has considered part of the curse of Adam.

ooo

An Important Polyphase Motor Decision.

In the Circuit Court of the United States for the District of Rhode Island, Mr. Justice Brown has just rendered a decision and opinion in the suit of the Westinghouse Electric and Manufacturing Company *versus* the Royal Weaving Company for infringement of the Tesla patents for polyphase motors. The opinion grants an injunction against the Weaving company, although it reserves decision as to whether the defendant may be permitted temporarily to use the motors which it now has installed.

The opinion of the court in full is as follows:

This is a petition for a preliminary injunction against infringement of patents No. 381,968, No. 382,279 and No. 382,280, granted May 1, 1888, to Nicola Tesla. These patents have been sustained, after full consideration, by the Circuit Court of the United States for the District of Connecticut in a suit against the New England Granite Company *et al*, 103 F. R., 951; and by the Circuit Court of Appeals for the Second Circuit, in the same case, 110 F. R. 753.

The defendant cites the language of the Supreme Court of the United States in Mast, Foos & Co. *vs.* Stover Mfg. Co., 177 U. S., 485:

"Comity, however, has no application to questions not considered by the prior court, or, in patent cases, to alleged anticipating devices which were not laid before that court.

"As to such, the action of the court is purely original, though the fact that such anticipating devices were not called to the attention of the prior court is likely to open them to suspicion."

The defendant contends that this Court should not be governed by the prior decisions, for the reason that it has before it new issues and new evidence.

The defendant relies principally on the French patent to Dumesnil, No. 161,564, dated August 8, 1884; and upon the French patent to Cabanellas, No. 168,172, dated April 9, 1885. It is said that the Dumesnil and Cabanellas patents disclose what was not before the courts of the Second Circuit, namely, that two single-phase synchronous motors could be coupled together, as by having their armatures mounted on the same shaft; and that these two motors might be run each by its own circuit of alternating currents, which might be supplied either by two single-phase alternating-current generators mounted on the same shaft, but so as to give currents out of phase with each other, or that a single generator such as was known in the prior art and which furnished the alternating currents of differing phase, might have been used as the source of supply.

While some of the general expressions of the opinions might have been modified, had the Dumesnil and Cabanellas patents been presented to the courts of the Second Circuit, a somewhat careful and laborious examination of these patents, and of the interpretations of them by experts, leads to the conclusion that these patents, if produced to the courts of the Second Circuit, would not have affected their decisions as to the nature and novelty of Tesla's invention, and as to the validity of the patents in suit. Neither does it seem to me that these patents would have affected the conclusion that the invention of Tesla was one of great novelty and merit.

The question whether Tesla was anticipated in the production of a rotary magnetic field for power purposes, by the use of alternating currents of different phase, was fully and elaborately argued in these cases, and fully and closely considered by the courts. By the decisions, it was found that:

"Tesla's invention, considered in its essence, was the production of a continuously rotating or whirling field of magnetic forces for power purposes by generating two or more displaced or differing phases of the alternating current, transmitting such phases, with their independence preserved, to the motor, and utilizing the displaced phases as such in the motor."

Also that he was the first to produce, by alternating currents, for power purposes, the shifting of the polar lines of the annular magnet through the entire circumference of the ring by the action of the magnetizing forces properly related.

A magnetic field wherein, by the cooperative action of two alternating currents, a resultant polar line progresses continuously towards the strengthening current, thus producing an effect as if a permanent magnet has been carried bodily around a rotable armature, I am unable to discover in the patents of Dumesnil or Cabanellas.

It is immaterial, therefore, to consider whether Tesla was the first to disclose the use of two alternating currents of different phase to rotate a shaft, or the criticism of those expressions in the opinions which may attribute to Tesla priority in the disclosure of the use of alternating currents of different phase for power purposes.

The decisions upheld the Tesla patents, and these patents well describe and claim the rotary magnetic field.

The sphere within which the defendant must show anticipation is narrower than that of the use of alternating currents of different phase, with an ultimate object of rotating a shaft. This renders much of the matter in the defendant's affidavits irrelevant to the question whether the prior decisions are controlling upon this petition for a preliminary injunction.

Narrowing the question, then, whether the defendant has disclosed any anticipation of the rotary magnetic field for which Tesla's patents were upheld, we will consider the contention based upon the Dumesnil and Cabanellas patents.

While the fact that these patents, though pleaded in previous litigation, were not put in evidence or brought before the courts, tends to awaken the suspicion that they have heretofore been considered too remote from the real questions presented by the Tesla patents, the defendant is still entitled to a consideration of the argument which it bases upon these patents.

Considering first the Dumesnil patent, and the drawings which are offered to show the "double crank action" of the alternating currents could, by their combined use, produce such magnetic effects as would be sufficient in themselves to rotate an armature; much less a suggestion that, by the combined use of two currents, a continuous rotary effect could be produced like that of a magnet carried bodily around the armature.

To couple two single-phase synchronous motors upon one shaft, displacing the poles of one armature angularly with respect to the other, so that one motor expends its maximum effort while the other expends its minimum effort, does not seem to me to exhibit the Tesla invention as described and claimed in the Tesla patents. In the opinion of Judge Shipman, it is stated that "Tesla must have a continuously rotating field."

The combination of two single-phase machines may have a "resultant" as distinguished from a summative effect upon the shaft; but the "resultant" of the operation of two machines is a different thing from the magnetic resultant of two currents upon a common element, as a Tesla ring or an armature within that ring.

If two single-phase machines are capable of rotating a shaft better than one machine, it is because the mechanical action of each single-phase machine is communicated through a shaft to assist the other machine. The armature of one machine would then be subjected, first, to a magnetic effort from its own field magnet, then to a mechanical effort from the shaft, which would bring it in position for the next magnetic impulse. The whole operation of the two single-pnase machines in combination would be from intermittent magnetic and mechanical efforts—neither magnetic field would be a rotary.

To show Dumesnil's combination of two single-phase machines, however, it is necessary to add another factor: The action of the magnetic poles of his armatures. Dumesnil nowhere suggests that continuous rotary action or tendency will result without the opposition of the magnetism of the armature to the magnetism of the field poles, or that by induction the field poles will properly magnetize the armature. Dumesnil, therefore, does not anticipate, since he fails to show that two alternating currents can, merely by combination of their magnetic effects, produce a continuous rotary effort, or that the action of two different magnetic forces upon a common element will give a resultant magnetic pole which exerts its force at positions intermediate of the field poles.

If we concede that Fig. 9 of the Hering affidavit might be considered as a mere mechanical consolidation of Figs. 7 and 8, we can not accept the statement that Dumesnil shows beyond question the arrangement of Figs. 7 and 8, as adequate to produce a constant rotary effect upon a shaft. Dumesnil nowhere discloses or suggests the idea

that such an electrical device as is shown in Figs. 7 and 8 can produce a rotary effect upon a shaft. The magnetic poles of the armature are described by him as features essential to rotary motion. His patent must be considered as a mere publication, giving a description and plan of operation. To make figures of the Hering affidavit illustrate both Dumesnil and Tesla, it is necessary to ignore what Dumesnil proposes as an essential feature.

Dumesnil, in my opinion, does not show a magnetic polar line, which is the resultant of two alternating currents of different phase; neither does he show any plan for producing a rotary effect merely by the unaided action of two alternating currents.

THE PATENT TO CABANELLAS.

This patent, upon many readings, seems to me to be fairly characterized by the complainant's counsel as "expressed in such obscure and indefinite terms as to be hopelessly unintelligible, except in a few unimportant particulars," and as requiring an exceptional exercise of the imaginative powers in translating its phrases into electrical diagrams.

It is contended that Cabanellas, like Dumesnil, contemplated arranging two single-phase machines side by side with the elements displaced so as to displace the phases of the currents, and thus get a continuous rotary effort from two currents. But, like Dumesnil, Cabanellas fails to show a magnetic pole which is the resultant of two alternating currents. When, therefore, the defendant's experts say that the armatures of Dumesnil and Cabanellas are caused to rotate "by the rotation of resultant magnetic attractions set up the joint action of two or more alternating currents of different phases," and that "these features of the prior Dumesnil and Cabanellas patent cover the ground of the Tesla patents in suit, and in substantially the same manner when the said patents are given a broad interpretation in accordance with the decisions of the court;" their testimony must be regarded as based upon a misinterpretation of the decisions of those courts, and upon a failure to recognize that it was expressly found that Tesla must have as a resultant of the currents a continually rotating field of magnetic forces. The "resultant" of the decisions is that which is produced by combining upon a common element the magnetism created by two alternating currents. This magnetic resultant, applied to power purposes, I understand to be the Tesla invention. The defendant's "resultant" is not a magnetic resultant, but merely the rotation of the armature.

Conceding that Dumesnil, Cabanellas, and Tesla all rotate an armature, the point for comparison is as to the way in which this rotation is accomplished. Conceding, further, for the purposes of this petition, that all employ alternating currents of different phase, Tesla alone discloses means whereby two alternating currents may so magnetize a common element as to produce a force with a constant rotary effect. Dumesnil and Cabanellas at best show the combined use of two motors of an old type having the characteristic defects of such motors, and lacking the characteristics of the Tesla motors. Even if two of these motors can assist each other by so timing their mechanical efforts that one exerts its maximum effect while the other exerts its minimum effect, I do not find in such a combination of two machines the invention of Tesla, nor the "rotary field" which was apparently conceded by the defendant in the prior suits to be the proper subject-matter of controversy in determining the validity of the Tesla patent.

This defendant seeks to show anticipation by an interpretation of the prior decisions which is too broad; and does not, in my opinion, show anticipation of what was decided to be the Tesla invention, and the subject-matter of his patents.

The question of infringement seems to be substantially determined by the prior decisions.

The question of laches and estoppel do not require extended discussion. These matters were ably and carefully presented at the hearing, and the opinion formed by me at that time was adverse to these contentions. Upon an examination of the entire record relating to these points, my opinion is confirmed that this defendant decided the question of adopting its motors as a mere business proposition; that it contemplated, as a part of this proposition, the risk of infringing the complainant's patents, and took the risk with its eyes open, relying upon protection from its vendors or from others; consequently, upon this hearing, it must stand by its business proposition. I fail to see that the defendant has in any way been inequitably treated by the complainant.

It is implied by the argument that if a patentee does not see fit to shape his business to suit the wishes of persons who desire to use his invention, this in some way creates an equity which entitles such persons to use the invention in such specific form as they prefer, without the consent of the patentee. I see no ground for thus abridging the rights of the patentee.

The objection to granting a full preliminary injunction is the hardship which would result to the defendant and its employés from preventing the use of the motors now installed in the defendant's factory. This objection, however, is insufficient to deprive the complainant of all right to a preliminary injunction, but goes rather to the question of the extent of the decree. The record upon this petition is voluminous; and we must recognize the possibility of error upon a subject of considerable complication and difficulty and should seek to avoid so far as possible mischief which might arise before such error can be corrected. It is also due to the complainant that we should recognize that it has established the validity of the patents after meeting and overcoming a most skillful and elaborate defence; and that its rights, thus established, should not be evaded or rendered worthless by unnecessary delay in their enforcement. While there are objections to determining questions like those raised upon this petition, save upon final hearing, the court must also consider that it is objectionable to refuse an injunction merely because of voluminous or complicated matters of defence.

This defendant, to avoid the effect of the former decisions, should show, not only that new matters and new issues are presented but that the new matter might require a different decision as to the character of Tesla's invention and as to the validity of his patents. Though the argument for the defendant has been presented forcibly and with ability, I am of the opinion that the defence to this petition is insufficient, since it does not seem to me to meet the points actually decided by the Courts of the Second Circuit.

Upon the complainant's brief, it is suggested that the order for a preliminary injunction can be granted upon terms which will impose no hardship or unnecessary damage upon the defendant, its employés, or the public. To such an injunction, with special terms as to the motors actually installed and in use in the defendant's factory, I am of the opinion that the complainant is entitled. Under all the circumstances, it would seem hardly necessary to make an immediate order permitting or requiring the gradual substitution of licensed for unlicensed motors. The complainant probably can be sufficiently protected as to these motors by a suitable bond, and by terms as to the speedy prosecution of the case to a final decision. The questions whether the defendant may be permitted to continue temporarily the use of the motors now installed and if so upon what terms, are reserved.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

MR. NIKOLA TESLA requests us to state that his office and laboratory have been removed to Wardenclyffe, Long Island, N. Y., and that all correspondence should be addressed there.

CURRENT NEWS AND NOTES.

TESLA PATENT LITIGATION.—Judge Lacombe, in the United States Circuit Court, New York City, on June 4, denied the application of the Westinghouse Electric and Manufacturing Company for an injunction to prevent the Stanley Electric Company from manufacturing apparatus claimed to come under certain Tesla patents. The refusal was made on the ground that the Stanley company manufactured the appliances in Pittsfield, Mass., and that, therefore, the matter was not within Judge Lacombe's jurisdiction. The question of the alleged infringement of the patents was not considered. The case was argued last week, the defendants being represented by ex-Speaker T. B. Reed, ex-Patent Commissioner Mitchell, and Mr. W. H. Kenyon.

The New York Herald June 9, 1902

USES ELECTRICITY WITHOUT A MEDIUM

Scientist Declares He Can Apply Atmospheric Current Without Motive Force.

WAS SIMPLE DISCOVERY

Senor Clemente Figueras, Engineer, of Canary Isles, Inventor of the Method.

[SPECIAL CABLE TO THE HERALD.]

The HERALD'S European edition publishes the following from its correspondent:—

LONDON, Monday. — A most remarkable claim, the genuineness of which it is as yet impossible to test, says a cable despatch published by the Daily Mail from its Las Palmas correspondent, has been made by Señor Clemente Figueras, Engineer of Woods and Forests in the Canary Islands, for many years professor of physics at St. Augustine's College at Las Palmas.

It seems that for many years he has been working silently at a method of directly utilizing atmospheric electricity—that is to say, without chemicals or dynamos—and making a practical application of it without the need of employing any motive force.

A true revelation might rob him of his reward, and even now, while he claims to have succeeded, he is silent concerning the exact principles of his discovery.

He asserts, however, he has invented a generator by which he can collect electric fluid so as to be able to store it and apply it for infinite purposes—for instance, in connection with shops, railways and manufactures.

He says he expects its effect will be a tremendous economic and industrial revolution. He will not give the key to the invention, but declares that the only extraordinary point about it is that it has taken so long to discover a simple scientific fact.

He intends shortly going to Madrid and Berlin to patent his inventions.

In addition to the discovery, the Daily Mail says that, according to letters received in London from his friends in Teneriffe, Señor Figueras has constructed a rough apparatus by which, in spite of its small size and defects, he obtains a current of 350 volts, which he utilizes in his own house for lighting purposes and driving a motor of twenty horse power.

His inventions comprise a generator, a motor and a sort of governor or regulator, the whole apparatus being so simple that a child could work it.

ELECTRICIANS IN CONVENTION

NOTABLE GATHERING IN GREAT BARRINGTON TO-MORROW.

One Feature Will Be a Test of Overland Wireless Telegraphy Over the Greatest Distance Yet Attempted—Many Learned Papers and Social Fetes.

One of the features of the nineteenth annual convention of American Electrical Engineers to be held in Great Barrington, Mass., to-morrow and the rest of the week, will be a test of long-distance, overland wireless telegraphy at the summer home of William Stanley, president of the Pittsfield Electrical Works.

Mr. Stanley has had constructed a station on the grounds, and has had a similar one at Watch Hill. From these two private messages will be sent and received, and if they are successful they will be the longest overland wireless communications that have yet been attempted.

Many distinguished scientists will attend the convention, including Mr. Edison, Prof. Thomson, Prof. Pupin, Dr. Kennedy, Mr. Tesla, Prof. Williams, Dr. Perrine, Dr. Kelley, Stephen Field and many others from all parts of the country.

These annual conventions have previously been held in some of the large cities of the country, but this season the institute decided to break away from time-honored precedents. They argued that a certain amount of pleasure could be combined with the business to be transacted, and that in the up-to-date summer resort the former coould be found.

GREAT PREPARATIONS.

In return for the honor done its town the prominent citizens of Great Barrington are making most elaborate preparations to receive their distinguished visitors, and for five days the town will be practically turned over to them. As this village is in close proximity to Lenox, Stockbridge and Pittsfield, they also propose to do their share in the way of entertaining. Local committees have been formed who are arranging the details, and these committees contain the names of men who are well known in the business and social world of New York, and who have their summer homes in the Berkshire Hills.

The visitors are expected to arrive from New York by a special train to-morrow afternoon, and in the evening a large reception will be given to them at the Berkshire Inn. There will be addresses of welcome and a banquet, followed by a dance.

PAPERS TO BE READ.

The convention proper will have one morning session each day. The first will be devoted to the steam turbine, with papers by Prof. Francis Hodgkinson on the Parsons turbine, and by R. R. Bowker on the De Laral turbine.

Another session will be given up to electric railroading, the education of electrical engineers, and to technical papers. Some of those who are to speak, and their subjects, are:

"A New Photometer for Incandescent Lights, and Similar Sources," Prof. C. P. Matthews, of Lafayette, Ind.; "The New Generating Plants of the Niagara Falls Power Co.," Harold W. Buck, of Niagara Falls, N. Y.; "A New Type of Current Tracing Instrument," Prof. R. B. Owens, of Montreal; "Notes on Railway Speed-time Curves.," by C. O. Mailloux, of New York;" Commutation, by David B. Rushmore, and many others that will be of interest even to outsiders.

During the afternoons the learned visitors and any members of their families who may accompany them will take drives through the picturesque parts of the country about Lenox, Stockbridge and Sheffield and visit the many places of historic interest.

MANY FETES PLANNED.

Probably the most brilliant entertainment of any that has been planned will be a lawn party that Mr. and Mrs. Stanley will give at their residence, Brookside, on the second day of the convention. This place is one of the most beautiful among the many splendid homes found in this part of the country.

Thursday will be strictly Great Barrington day, for in the afternoon the golf club will give an open-air concert, there will be May-pole dances by children of the village at the fair grounds, and in the evening a real country dance will be given.

The particular feature of Friday will be a visit to the Stanley Electrical Works at Pittsfield. After an inspection of the works Prof. and Mrs. Perrine will give a lawn party in honor of the guests at their charming place just out of Pittsfield.

In addition to these public affairs, several private dinners and other entertainments will be given. On Saturday, June 21, the distinguished party will say good-by, and will be conveyed by special train to New York.

This same wonder of wireless work is possibly destined to further feats in the great future of scientific civilization. Not merely in the way of beautiful laboratory phenomena, but rather in the domain of human wants and practical industry. Along Tesla's lines, why can not large quantities of electrical energy be transmitted as well as the pigmy potentials now successful? Should it be any more difficult than the development of the giant steam hammer used on armor-plate from the little tack-driver Artemus Ward used to fatten his thumb?

A New Tesla Laboratory on Long Island.

The public is always very much interested in whatever Mr. Tesla may say or do, and we are very glad, therefore, to have the opportunity of presenting herewith two views which have been forwarded us by a correspondent on Long Island, showing his new laboratory at Wardenclyffe, L. I., and the interesting tower that is associated with it. It will be remembered that after the unfortunate destruction by fire some years ago of his laboratory, near Bleecker Street, New

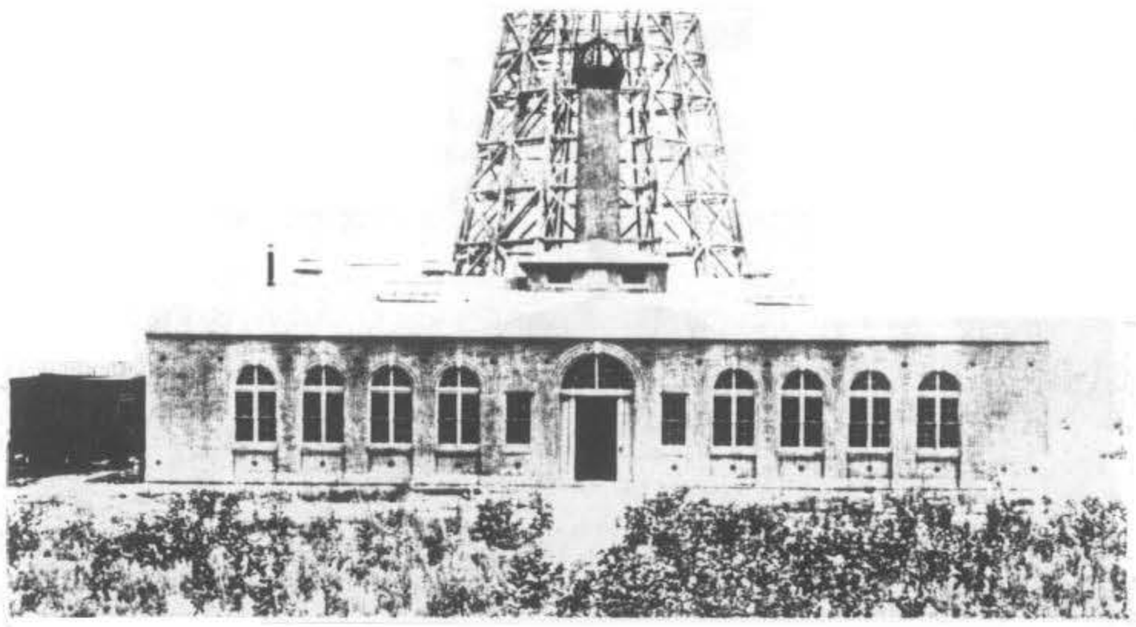


FIG. I.—TESLA LABORATORY AT WARDENCLYFFE, L. I.

York City, Mr. Tesla established himself in East Houston Street, where a great deal of interesting work and many new inventions have resulted from the indefatigable labors of this well-known inventor. It would appear, however, that Mr. Tesla has needed more seclusion and quiet than could be obtained in the city, where his laboratory is not only the rendezvous of inquisitive reporters, but is the center of pilgrimages from all parts of the world of those who have heard of his work and desire to meet him, either from sheer curiosity or for legitimate purposes of scientific inquiry or industrial development. Hence Mr. Tesla has now, like Mr. Edison, established himself out of town, yet within easy reach of the metropolis.

The new Tesla laboratory at Wardenclyffe is about 65 miles from New York, or 1½ hours by fast train on the Long Island Railroad. According to the statement, quoted in our columns last year, from a circular as to Wardenclyffe, "This property was purchased from the North Shore Industrial Company, which owns an estate of something more than 1,600 acres adjoining, under an agreement that the Wardenclyffe Building Company shall have the first right and privilege to do all building and make all constructional improvements of said North Shore Industrial Company, and shall have the first right of purchase of any additional land offered by it for sale, and under which contractual rights large profits will be realized in the future. In addition to this exceptional advantage, Mr. Nikola Tesla, the foremost electrician of the age, whose achievements in electrical science eclipse in practical importance all other discoveries of the century, has just closed a contract to expend at Wardenclyffe a very large sum of money in constructing electrical laboratories and the main station for his wireless telegraphy system of communication with Europe and Australasia. This development will require

a large number of houses for the accommodation of the several hundred of people whom Mr. Tesla will employ." It was further stated that the real estate enterprise is backed by Mr. Chas. R. Flint, the well-known merchant, and that Mr. Tesla is to occupy a cottage in the vicinity of the Wardenclyffe Inn.

We are not able to give any details as to the equipment of the work, other than that some little while ago Mr. Tesla placed a con-

FIG. 2.—TESLA TOWER AT WARDENCLYFFE, L. I.

tract with Westinghouse, Church, Kerr & Company for a power plant equipment. As might be expected, and in keeping with Mr. Tesla's custom in such matters, great privacy and secrecy are observed in regard to the laboratory, and the visitor who can secure entrance is indeed a lucky man, while at the same time he is likely to be an ignorant one, unable even to conjecture the meaning of what he may see going on around him. It has been stated that the large tower, shown in one of our cuts, is intended for wireless telegraphy and wireless power transmission experiments, and that underneath it is an excavation as deep as the tower is high, possibly for the purpose of perfect ground connection. A subway with conduits leads from the laboratory or factory proper to the tower.

NIKOLA TESLA FINED $100.

For failing to appear in answer to a summons for jury duty, Nikola Tesla, the electrician, was fined $100 by Judge Foster yesterday. He will have to explain or pay or go to Ludlow Street Jail.

The New York Sun October 8, 1902

NIKOLA TESLA FINED $100.

Fails to Show Up for Jury Duty in General Sessions—Is Sorry Now.

Nikola Tesla, the electrician, was fined $100 by Judge Foster in Part I., General Sessions yesterday, for failing to appear as a talesman on the jury panel of that court for the October term.

Mr. Tesla said last night that he had overlooked the summons, because he had been absorbed in very important work, and, besides, had been away on Long Island for three days

"I got the notice too late," explained Mr. Tesla, "but, nevertheless, I will apologize to the Court. When I become absorbed in my work I forget everything else."

The New York Tribune October 8, 1902

NIKOLA TESLA FINED $100.

HE FAILED TO OBEY A SUMMONS FOR JURY DUTY

For failing to appear in answer to a summons for jury duty Nikola Tesla, the inventor, was fined $100 by Judge Foster, in Part II, General Sessions, yesterday. Unless he can give a good reason for his failure to appear in court he will have to pay the fine, the alternative being imprisonment in Ludlow Street Jail.

The New York Herald October 9, 1902

CITY JOTTINGS.

Nicola Tesla, inventor, explained to Judge Foster, of the Court of General Sessions, yesterday that because of absent mindedness he did not answer a summons for jury duty. The fine of $100 was remitted.

The New York Tribune October 9, 1902

NICOLA TESLA'S FINE REMITTED.

Nicola Tesla, the electrical inventor, on whom a fine of $100 was imposed on Tuesday by Judge Foster, in the Court of General Sessions, for failing to answer a summons for jury duty, appeared in court yesterday and explained to Judge Foster that he was very busy at the present time and had overlooked the summons. He said that he meant no disrespect to the court, and that it was merely a case of absentmindedness. The fine was remitted, and Mr. Tesla was excused until October 15 on account of his business.

The New York Times October 16, 1902

COURT EXCUSES TESLA.

Inventor, Summoned in Murder Case, Termed the Death Penalty Barbarous, Inhuman, and Unnecessary.

Nikola Tesla, the electrical inventor, was excused from jury duty in a murder case yesterday on account of his views on capital punishment. Mr. Tesla stated emphatically that he thought the infliction of the death penalty not only barbarous and inhuman, but unnecessary as a factor in the scheme of modern civilization.

The inventor was called as talesman in the case of Michaele La Mendola, an Italian, who is being tried on a charge of murder in the first degree before Judge Warren W. Foster in General Sessions. La Mendola is accused of having killed Micapro Alangi, another Italian, in an altercation over $6 last January.

Only a week ago Mr. Tesla was fined $100 by Judge Foster for failing to obey a summons to jury duty, also in a capital case. The fine was later remitted, when Mr. Tesla explained that he had been very busy and overlooked the summons.

The New York Tribune October 16, 1902

TESLA AGAINST DEATH PENALTY.

SO THE ELECTRICIAN IS EXCUSED FROM JURY DUTY IN LA MENDOLA MURDER TRIAL.

Nikola Tesla, the electrician, was excused from jury duty yesterday in the trial of Michael La Mendola, for murder in the first degree, because he said emphatically that he did not believe in capital punishment. A few days ago Mr. Tesla was fined $100 because he failed to obey a summons for jury duty. When he appeared and said that he was so absorbed in his work that he overlooked the summons the fine was remitted, and he was excused until yesterday.

La Mendola is accused of having been a party to the killing of Micapio Alangi, in January last. La Mendola and his son Samuel got into a fight with Alangi, during which Samuel La Mendola shot and killed Alangi. The fight was over the ownership of $6. The defence is that Alangi tried to kill Samuel's father, and that Samuel prevented it by shooting. Samuel pleaded guilty to murder in the second degree on March 16, and is now serving a life sentence.

When Mr. Tesla was called he was asked by Assistant District Attorney Ely if he believed in capital punishment, when the death penalty was warranted by the finding of a jury.

"I do not," replied Mr. Tesla. "I think it is barbarous."

"Well, Mr. Tesla," interposed the judge, "you would uphold the laws of the State which are on the statute books, would you not?"—

"I would within my power and reason," was the reply, 'but I do not believe that capital punishment is proper. I do not see how one person can condemn another to death. I could not.'

Mr. Tesla was excused for the term because of his views. After a jury had been obtained the trial was adjourned for the day

Tesla's New Laboratory.—In a recent issue of the *Electrical World* illustrations are given of the new Tesla laboratory at Wardenclyff, and of the large tower erected near by for experiments in wireless telegraphy and the transmission of power. The reasons which have induced Mr. Tesla to erect his new laboratory 65 miles away from New York are given in a short article. Amongst these is the isolation of this expert from the reporters of the daily papers. If this can only be accomplished we think that the move will be a most valuable one, but we are afraid that Mr. Tesla will not be free from the effects of the encouragement which he has given to these gentlemen in the past. With respect to the tower, we regret that no dimensions are given. It consists of a vertical cone of iron girder work, on the top of which there appears from the illustration to be a large disc. It is said that the tower stands on a hollow base excavated in the ground and of practically equal dimensions There is only one small building near the tower, and from the character of this we infer that the height of the tower is considerably over 150ft. It will be interesting to see whether the announcements concerning the object and use of this tower will be communicated first to a scientific society, or to the reporter of one of the New York newspapers.

Tesla Motor Patents in Litigation.

In the infringement suit which the Westinghouse Electric and Manufacturing Company brought against the Catskill Illuminating and Power Company some interesting facts appear concerning the Tesla motor. The case was decided in favor of the Westinghouse company by the United States Circuit Court of the Southern District of New York, but has been carried up to the United States Circuit Court of Appeals by the Catskill company. The appealed case was called for Monday, November 10th, but was postponed until last Monday, at which time it came up for a rehearing. In the brief for the appellant, prepared by Charles A. Brown of Chicago, many interesting historical facts are presented.

The patents on which it is claimed the Catskill company is infringing were applied for by Nikola Tesla on December 8, 1888. These patents were granted as improvements to prior patents granted to the same inventor, and relate to the rotating-field motor. The infringement proceedings involve the working principles of the Scheefer meter.

An idea of the slight knowledge of the action of the electric current in dynamo-electric machines some 14 years ago may be obtained from the following, which is an extract from a paper read before the American Institute of Electrical Engineers by Mr. Tesla in May, 1888: "In our dynamo machines, it is well known, we generate alternate currents which we direct by means of a commutator, a complicated device, and, it may be justly said, the source of most of the troubles experienced in the operation of the machines. Now, the currents so directed cannot be utilized in the motor, but they must—again by means of a similar unreliable device—be reconverted into their original state of alternate currents. The function of the commutator is entirely external, and in no way does it affect the internal working of the machines. In reality, therefore, all machines are alternate-current machines, the currents appearing as continuous only in the external circuit during their transit from generator to motor. In view simply of this fact, alternate currents would commend themselves as a mere direct application of electrical energy, and the employment of continuous currents would only be justified if we had dynamos which would primarily generate, and motors which would be directly actuated by, such currents.

"But the operation of the commutator on a motor is twofold; first, it reverses the currents through the motor; and, secondly, it effects, automatically, a progressive shifting of the poles of one of its magnetic constituents. Assuming, therefore, that both of the useless operations in the systems, that is to say, the directing of the alternate currents on the generator and reversing the direct currents on the motor, be eliminated, it would still be necessary, in order to cause a rotation of the motor, to produce a progressive shifting of the poles of one of its elements, and the question presented itself—How to perform this operation by the direct action of alternate currents?" From the above one easily understands what rapid strides have been made in the applications of electricity since that time. It seems scarcely possible to realize how short a time it has taken to develop a science which, 15 years ago, was just becoming known to the inventor.

Another instance of the work being done on the alternating current is shown in a paper written by G. Ferraris in April, 1888. He conceived the idea of the rotating-field principle or mode of operation of a motor obtained by the direct action of two out-of-phase alternating currents in fixed energizing coils of the motor, and he embodied it in illustrative apparatus and lectured at the Turin Institution on the subject, a full disclosure of his work having been published on April 22, 1888. The important thing in the mind of Ferraris was the motor and its rotating-field mode of operation, and that the method of producing the required out-of-phase alternating currents was of no consequence. Records show that for four or five years he had been working on inductive and other split-phase methods, measuring the difference of phase obtained under different conditions and generally determining the laws of transformers, the differences in phases of currents, the retardation of induction, etc.

Mr. Ferraris treated the obtaining of the necessary out-of-phase relationship of the currents as a manifest thing. Either two independent and originally out-of-phase currents of the same period or rapidity of alternation could be employed, or the two could be obtained from a single alternating current. And he describes three ways of obtaining them from a single alternating current, and describes it as manifest and well-known matter in the following: "The effects above described may be produced (the rotating magnetic field) by means of a single alternating current. It is, in fact, always possible in various ways to obtain the two currents necessary to produce the component magnetic forces from a single alternating current, and to vary the difference of phase between them within certain limits. One way of doing this is by letting the current pass through the primary coil of a transformer. Then the original current and the induced current are at our disposal.

"Another method of obtaining the same result consists in producing the two component fields from the two secondary currents produced in two transformers, or in two portions of the same transformer traversed by the primary current. Finally, to produce the forces, two derived currents can be used. If in one of the circuits resistances free from self-induction are introduced, and in the other circuit a coil of small resistance and high self-induction, it may be brought about that, while the mean intensities of the two curents are equal, or have a predetermined ratio, the phases of the currents themselves differ considerably." Ferraris, from his knowledge of the electrical laws governing split-phasing predicted the failure of such a source of out-of-phase currents for power-transmission purposes, but suggested the utility for meter purposes, a prediction which has been fulfilled by the present developments of the art.

Again, Shallenberger, in the spring of 1888, developed a meter having a rotating-field motive device run by out-of-phase currents, obtained by split-phase apparatus from a single source. The device was gotten up as a meter for single-phase alternating-current systems, just then coming into use.

Borel and Paccaud devised a motor apparatus operated by split-phase currents some time in 1887, the publication and patents occurring in the summer of 1888.

Meylan, in La Lumiere Electrique, July 14, 1888, describing the Borel meters for alternating currents, says, in the course of a description of the work of Ferraris, and after setting out the rotating idea: "How is it possible now to attain the two alternating currents which we need? Nothing is simpler, and there are many means offered us for that; in the first place by the use of a transformer; one of the coils is inserted in the primary circuit and the other in the secondary circuit. . . . Another arrangement that allows of obtaining currents with a difference of phase consists in putting the two circuits in multiple arc and in inserting in one of the branches a large self-induction." Thus the idea of using split-phase currents and split-phase apparatus for producing the necessary out-of-phase currents seems to have come naturally to all to whom the rotating-field motor idea became known, and the fact that such a motor required two or more out-of-phase alternating currents.

What all the technical men of that day seem to have been seeking for, was the modern economical multiphase system of transmitting power. The Tesla motor required double circuits, and these the inventors were trying to do away with by some means which would still retain the full and undiminished power-carrying capacity of the currents.

The Tesla invention of the May 1, 1888, patents solved the problem of the utilization in a motor of double-phase alternating currents for power-transmission purposes, and did this by a peculiar construction of motor, to wit, with two or more independent energizing circuits and such a connection of those circuits with the source or sources of the double-phase currents (an alternating-current dynamo) that that out-of-step characteristic of the currents was preserved in the energizing coils of the motor, and a rotating or whirling magnetic field was thereby produced, which caused the armature to start up and rotate.

The invention of the patents in suit, granted December 8, 1888, is not addressed to the utilization of two-phase currents in a motor, but to a way of producing the necessary two out-of-phase currents. Whereas, in the patents of May 1, 1888, the two-phase currents were produced separately in fact and in point of time by the separate coils of the ordinary polyphase alternating-current generator, in the patents in suit the two out-of-phase currents employed are produced from a single-phase alternating current, one being delayed or made to lag more than the other by the inductive or the derivative method. The original unitary current is divided into two currents, and the two are then artificially thrown out of step

with relation to each other, and in that condition they enter and operate the motor.

For a better idea of the relation of the two sets of Tesla patents to each other, the three diagrams, shown in Fig. 1 are given. The first is typical of the earlier Tesla patents and the second and third of the patents now in suit. In these diagrams are shown in dotted lines those parts of the apparatus that make use of the out-of-phase alternating currents after they are produced, and in full lines those parts of the apparatus which are involved in the production of the out-of-phase alternating currents prior to their utilization. (G) is the generator; (L), the line wires; (M), the motor; (a) and (b), the two independent energizing circuits of the motor; (I), an induction coil or transformer; (S), a self-induction coil; (R), a resistance coil. The line (x) (x) separates the current-producing parts of the systems from the current-utilizing parts.

The Scheefer meter, which, as has been said, is involved in the infringement suit, is shown in Fig. 6. Figs. 2, 3, 4 and 5 are diagrams of development stages. Fig. 2 represents a disk which is operated by means of a single energizing circuit, wound upon a field core similar to that of the Scheefer meter. This is wound upon one leg of the core and causes a rotation by means of a difference in the strength of the magnetic poles. It makes no difference whether this winding upon one leg of the core be a series or a shunt winding. In either case the meter will rotate and will be in one case a meter which will measure volts (that is, when it has a pressure winding), and which will in the other case measure current or amperes (when it has a current winding). The trouble with a meter like this is that it will not measure watts unless both windings are superposed, but when both windings are superposed upon the same leg of the core, as in Fig. 3, a rotation is obtained, which is in proportion to the volts times the amperes, or the watts, because both the pressure and the series windings are delivering their magnetic fluxes into the circuit and causing rotation of the disk.

The trouble with this meter, however, is that, because it is under the influence of the shunt winding at all times, even when there is no load connected in circuit, a rotation will ensue and the meter will register when there are no lights in the circuit. To obviate this difficulty, Mr. Scheefer put upon both legs of the core a shunt winding, and thereby secured two opposing balanced tendencies to rotation (Fig. 4), which exactly balanced each other. There would be no rotation, therefore, in the disk with this arrangement under no load. Now if to the shunt windings which thus balance each other in their effect upon the disk are added two series windings which assist the shunt winding on one leg and oppose the effect of the shunt winding upon the other leg, a rotation will ensue which is in proportion to the watts, and a wattmeter will be the result. This arrangement is shown in Fig. 5.

This is a meter which will operate to secure the same result as the Scheefer meter. The Scheefer meter, however, takes the series winding, and for convenience in arrangement, places it between the two legs of the magnet, and causes it to operate by its magnetic flux to strengthen one pole and weaken the other. It is by this last step that infringement is claimed.

While considering either one of the two devices (Figs. 5 and 6) it will be readily understood that the magnetic flux produced by the shunt winding upon the two legs of the magnetic cores creates a north pole at one end and a south pole at the other end. The series winding, whether placed upon each leg of the core or placed in the center between the two legs, operates by its magnetic flux to strengthen one pole and weaken the other. There results from this condition of unbalanced poles the following action: Each pole sets up in the disk eddy currents, which produce magnetic effects opposed to that of the core There will be repulsion, therefore, between the magnetic poles created in the disk and the magnetic poles of the field. The stronger pole, however, having a predominating effect, will drive away the polar region created in proximity to it upon the disk, and will thus overcome the opposing tendency of the other pole. In addition to this repulsion effect, there will be likewise an attraction between the strong pole and the polar regions of the opposite sign in the disk, which will tend to assist the rotation of the disk. The meter may have a difference of phase in the circuits of its two windings, but this depends wholly upon the character of the translating devices connected in circuit therewith. It continues to operate whether there is a difference of phase or not, and it operates according to the same principle of operation, whether there is a difference of phase between the currents of its energizing circuits or not.

The essential feature of the patents in suit is the rotating or whirling field of force. This rotating or whirling field of force, as defined in the Tesla patents, is produced by the blending of the fluxes due to the independent energizing circuits of the motor. As expressed by Mr. Ferarris in his disclosure of the inventions of the patents, "the magnetic fields produced by two electric currents are superposed" in order to produce the rotating field. The Tesla rotating or whirling field of force requires the superposition of the magnetic fluxes in one and the same space. Otherwise they do not lose themselves in a resultant. This superposition of the magnetic fields does not occur, and the operation of thereby securing a resultant in accordance with the law of the parallelogram of forces does not proceed in the Scheefer apparatus.

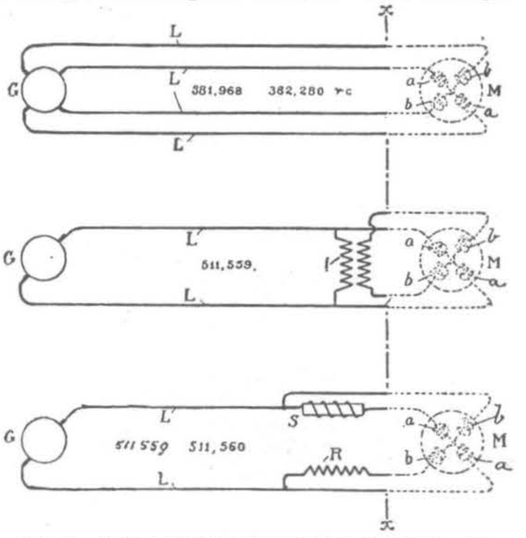

FIG. 1. TESLA MOTOR PATENTS IN LITIGATION. — DIAGRAMS OF TESLA PATENTS.

On the contrary, the arrangement of the parts necessary to bring about that operation is practically reversed. The fluxes or lines of force or operating magnetic fields of the two out-of-phase currents do not traverse the same space or cross each other at an angle in that space. As a consequence, there is no parallelogram of forces brought into play. Again, the fluxes due to the separate currents are exerted in lines that are parallel to each other and independent of each other and far apart, and they maintain their independence throughout. There is no resultant in the sense of the Tesla patents. The individual fluxes do not lose themselves in a resultant. There is no motion of a resultant which is essential to the rotation of the armature. In the Scheefer meter the currents coact, not on the principle of the parallelogram of forces, nor through the action of a resultant magnetizing force, the whirling of which whirls the armature, but on a different principle.

It does not operate by a difference of phase, but by a principle of attraction and repulsion, distinct from that of the Tesla patents. The defendant asserts, moreover, that the patents in suit are completely anticipated and void on that account.

TESLA MOTOR PATENTS IN LITIGATION. — DIAGRAMS OF SCHEEFER METER.

The Penalty of Fame.

The subjoined, from the *New York Journal,* is extraordinary, anyhow, and shows how the "people" note what is taking place: Since Judge Warren W. Foster imposed a fine of $100 on Nikola Tesla, the electrical inventor, for failing to obey a jury notice, the Judge has received a number of eccentric letters from Mrs. Annie Thierstein, of No. 239 East Fifty-fourth Street. One, which he received recently, was registered to insure its reaching the Judge. It reads as follows: "I must remind again you, Mr. Judge, as to Nikola Tesla, the electrician. He used me as a living telephone for his revolving motion, already since four years, causing ruin to my existence and good reputation. I lose all the parties for whom I do laundry work because the fine people of the West Side complain of the nuisance deriving from the telephonograph. Tesla knows all about the damage done by him for four years. He must give compensation for it, and cannot deny charge as I have witnesses. I desire, Mr. Judge, you would call us both officially as soon as possible. I already sent you three times to assist me. I am not bound to take my own life for want of work and means. Tesla drives me to despair. He is an unscrupulous fellow. He, unconcerned, looks on at his living telephone as it wastes away in misery. I trust, Judge, you won't forget calling Tesla to task." Judge Foster says he does not know exactly what he will do with this "human telephone," but declared his secretary would probably attend to the matter.

THE
ELECTRICAL AGE
NEW YORK

VOL. XXX FEBRUARY, 1903 No. 2

Nikola Tesla, His Work and Unfulfilled Promises

By LAURENCE A. HAWKINS, E. E.

THAT commendation on the part of the public which we call fame is a prize struggled for throughout the world. It is as distinctly valuable as a mine, a 20-story building or any other property, and, in the estimation of many, great fame is of more value to its possessor than would be any section of mines or 20-story buildings. It is wise, then, on the part of society to see that this valuable thing, fame, is distributed justly.

Ten years ago, if public opinion in this country had been required to name the electrician of greatest promise, the answer without doubt would have been "Nikola Tesla." To-day his name provokes at best a regret that so great a promise should have been unfulfilled. In ten years the attitude of the scientific press has passed from admiring expectancy to good natured banter and at last to charitable silence. In 1892 a leading electrical periodical of this country contained the following ("Electrical World," Vol. 19, p. 20):

"During the past six months Mr. Nikola Tesla has been steadily at work developing the beautiful principles that he enunciated in his striking lecture before the American Institute of Electrical Engineers. In his skilful hands the experiments have extended far beyond their merely theoretical importance in the direction of important practical applications. The revolutionary character of his methods will make any extensive application of them of unique interest." In 1898, the same journal, speaking of Tesla's latest patented scheme, says ("Electrical World," Vol. 32, p 466): "Mr. Tesla, if correctly re-

ported, previously proposed to wobble the earth's charge for man's ignoble uses, but he now, if these things can be taken seriously, has designs on the universe. The price of copper remains in the neighborhood of 11 cents, however." In 1900, a description of a Tesla patent which if practicable would revolutionize the electrical industry, is printed without one word of editorial comment. ("Electrical World," Vol. 35, p. 792.)

Tesla's career, since the time he first stepped into prominence by his lecture before the A. I. E. E. in 1888, naturally divides itself into three periods, which may be designated as the rotary field or patent period, the high voltage and high frequency or lecture period, and the present or newspaper period. It will be well to consider these separately in an endeavor to arrive at a just estimation of the man's work and of the value of his contributions to the engineering or scientific world.

Prior to 1884, the alternating current system of distribution, though older than the direct current system, was in little use. Gramme had taught the world how to build a satisfactory direct current commutator. Direct current seemed to have all the advantages of alternating current and would perform many services for which the latter was not suitable, notably electrolytic work. But in '83 and '84 Gaulard showed that the well known Ruhmkoff coil could be used to transform alternating current from high to low voltage, permitting of great economy in line wire, and he built and operated his transformer for lighting.

In 1885 Zipernowski & Deri produced a transformer of high commercial efficiency, and showed how to obtain excellent regulation, impossible with Gaulard's series system, by proper connection of the primaries in parallel. From this time alternating current began to be more used for electric lighting. One of the objections to the system was that there were no small self-starting motors that would operate efficiently on it. Accordingly, when Tesla announced, in May, 1888, that he had solved this motor problem, he at once became one of the most prominent figures in the engineering world. His solution was a theory of the combination of two or more alternating currents of different phase to produce a resultant rotating magnetic field. This same theory had been published in Italy a few weeks prior to Tesla by Ferraris. ("L'Elettricita," April 22, 1888.) Ferraris, however, contented himself with publication of the theory, while Tesla patented it, and followed up his first patents with a mass of other patents describing every conceivable construction and mode of operation that could in any way be imagined to embody his rotating magnetic field. It is for this reason that the rotating field theory is associated in this country with the name of Tesla rather than with that of Ferraris, although the contrary is the fact in every other country.

The idea of a rotating magnetic field as the resultant of two currents was not novel. It had been produced by Bailey ("Phil. Magazine," October, 1879) in 1879 with commutated direct currents, and by Deprez ("La Lumiere Electrique," December 8, 1883) in 1883 with alternating currents. It is scarcely conceivable that the application of these experiments would have escaped the eyes of the engineering world when the greater efficiency of polyphase alternators over single-phase alternators forced the former into general use. But that time had not come in 1888, and the motors described by Tesla, even if they had been commercially efficient struc-

tures, could not be operated on the circuits then existing.

Like Edison's three-wire system, the rotating field must have been obvious when changed conditions called for its application, but in 1888 it was not what was wanted. As Swinbourne said at the time ("Electrician," Vol. 21, p. 342): "The low efficiency is not at all the chief objection to the scheme. The whole arrangement is impracticable, as it demands special alternate-current generators and leads. Until Mr. Tesla can produce a motor which will work on alternate-current circuits as they are, and do that efficiently even with varying loads and without difficulty in starting, he can hardly be said to have solved the problem." The achievement of the Tesla and Ferraris publications was not the solution of a problem presented by existing conditions. They assumed non-existent and, at that time, impracticable conditions, and then applied the obvious principle of the rotating field of Bailey and Deprez. Had not experience subsequently proved the polyphase generator more efficient than the single phase, the rotary field of Tesla and Ferraris, like that of Bailey and Deprez, would never have become of more than academic interest.

In time the polyphase generator did prove its superiority per se, and brought polyphase motors of different types with it into commercial use. But engineering to-day owes Tesla no more than it owes Ferraris, Deprez or Bailey, for Tesla never produced a commercially successful motor. As the demand for polyphase motors gradually came into existence he worked hard to produce a commercial motor, but it did not appear in the market. The motors of the so-called fundamental patents failed absolutely to meet commercial conditions. Though the later Tesla patents describe multitudinous modifications, Tesla himself, with practically unlimited means at his disposal, seems to have failed to produce a commercial self-starting motor for power purposes. Undoubtedly Tesla's theory of magnetic laws, as shown in some of his patents depending on so-called magnetic screening and on reducing iron losses by removing the iron, was an important factor in his failure. But other engineers equally failed to reduce those patents to practice, although on one occasion, according to the sworn testimony of a prominent engineer, $100,000 was offered if he would make the Tesla motor operate successfully.

Two widely different classes of alternating-current motors are in general commercial use to-day. They are known as synchronous motors and induction motors. The two differ radically in principle of design, in theory of operation, in method of manipulation, in the necessary accessory apparatus and in adaptability to different kinds of work.

The synchronous motor is simply an alternating-current generator with its function reversed. The same machine, with no change whatever, runs equally well as generator or motor. This is true of either single phase or polyphase. The polyphase generator is two or more single-phase machines wound on the same frame, and the same is true of the polyphase motor. When the electrical world had polyphase machines given it, and was told that alternating-current generators, like direct-current generators, were reversible, it knew all that was necessary for the successful operation of polyphase synchronous motors. And it had the machines (United States patent, No. 218,520, Gramme; "Electrician," October 28, 1882, p. 565; Gordon's dynamo electric machine) and it

had the knowledge ("Jour. Soc. Tel. Eng." and "Electricity," Vol. 13, p. 496 and p. 515; "Electrician," November 15, 1884, p. 11; "Electric Illumination," by Dredge, London, 1882, Vol. 1, p. 69; "L'Electricien," August 1, 1884, p. 131; United States patent, No. 390,439) years before Tesla and Ferraris published the rotating field principle in 1888.

The synchronous motor, however, finds its applications in conditions of large power and continuous running. Those conditions are furnished by the great long-distance systems of power transmission of to-day, and it is only in such systems that the synchronous motor is or ever has been used. No such systems existed in 1888, and it was for this reason that though the reversibility of the alternating-current generator was known, it had never been utilized. The machine was there, but the conditions for its use were lacking. What was wanted then, and is wanted now, for general distribution and subdivision of power, was a small self-starting motor. This requirement is met by the "rotary field" or "induction" motor of to-day.

The man, in my opinion, to whom the induction motor is chiefly due is Dobrowolski. He was the first clearly to perceive the theory of its operation and the requirements in its design. To produce the maximum action of the alternating currents on the other member he perceived the necessity of a minimum magnetic air gap He gained the desired result, among other things, by imbedding the conductors in the iron, and his motor was a success. The first commercially successful induction motor of any size was the one built by him and exhibited at Frankfort in 1891. His designs were successfully copied in this country, and the induction motor of to-day became a fact.

After Tesla's apparent failure in motor production he turned to more promising fields. In 1891 he burst upon the electrical world with the first of a series of the most remarkable lectures ever delivered before a scientific audience. The experiments shown were fairly startling. Lamps and motors were operated on open circuit with a single-line wire. Lamps were made to burn brightly when short-circuited by a heavy copper bar, while exhausted tubes were brought to incandescence without any wire near them. Tubes were lighted by merely approaching them with the hand. Beautiful flames of varied appearance were made to leap from many objects, even from the hand of the lecturer himself.

Before the eyes of the startled spectators Tesla touched both terminals of a 200,000-volt transformer, with no more serious result than the production of the flames aforesaid. And throughout the lecture vague hints were offered of the tremendous possibilities exposed by the experiments—possibilities of obtaining unlimited light and power anywhere on the earth's surface, not by means of expensive wires from costly central stations, but by taking the energy directly from the earth itself or from the circumambient ether.

The public was astounded. Popular opinion, ever ready to ascribe the most impossible attributes to that vaguely understood force, electricity, hailed the lectures as disclosing a new era of wonders and Tesla as the last and greatest of electrical wizards. Even the eye of science was dazzled by Tesla's brilliant flames, and the most extravagant tributes were poured upon him. As stated in the London "Electrical Engineer": "No man in our age has achieved such a universal scientific reputation in a single stride as this gifted young electrical engineer."

It was asserted that similar effects to those shown by Tesla had previously been produced by Crookes, Hertz, Rayleigh, Spottiswood, Lodge, De La Rue, Kennedy and Thomson, some of those effects having been patented nine years before the first Tesla lecture (British patent, No. 4,752, Rankin Kennedy, 1882). But Tesla had made his experiments more spectacular by the use of higher voltages and higher frequencies, and the difference in degree passed for novelty in kind. It is true that the lectures abounded in fallacies and absurdities, as, for instance, Tesla's favorite theory of magnetic screening ("Inventions, Researches and Writings of Nikola Tesla," p. 185), his misconception of harmonics (Id., 187), his inexplicable statement regarding Arago's experiment (Id., 233), and even a gross misunderstanding of the fundamental law of physical science—the conservation of energy (Id., 147)—but all were overlooked or forgiven. Few, if any, measurements are recorded in the lectures; nor is there more than the feeblest attempt at even orderly sequence in the experiments, but spectacular sensationalism was accepted as a substitute for scientific methods. No attempt at any commercial adaptation of the experiments is described, but, instead, Tesla's vague hints at possibilities won him the reputation of prophet of the new era.

To-day, as we look back on those lectures of ten years ago and the developments since then, it is hard to understand the scientific enthusiasm Tesla aroused. Have any useful results ever come from those famous experiments? Instead of Tesla's high frequencies, the tendency has been steadily to lower frequencies. Instead of using static effects for power transmission, the chief problem on modern long-distance lines is to diminish those very effects. The electrostatic light is still a laboratory toy, while two wires and a filament are still used in commerce. Central stations still produce their power and distribute it through their mains. The prophecies of those lectures and articles are still unfulfilled, and their suggestions forgotten or disregarded. But ten years ago those who could see beyond the glamour of the Tesla tubes were few. Even then, however, there were some who regarded the lectures in the less spectacular light of science. The London "Electrical Review," in an editorial expressive of some bewilderment at the chaotic mass of experiments and of an inclination to suspend judgment until Tesla should have opportunity for further explanation through the press, calls attention to the fact that Tesla's work was not in a wholly unexplored field. (London "Electrical Review," Vol. 30, p. 184.) "The Electrician" at first called attention to the fact that the experiments were not new, but consisted "in repetitions of well-known effects on a large scale" ("Electrician," Vol. 28, p. 395), and later expressed itself conservatively as follows ("Electrician," Vol. 31, p. 139): "If a few quantitative determinations of current, voltage, or even of frequency, had been given in the lecture it would have had a definite scientific value. To reduce even one out of the 50 experiments to a complete reasearch would be worth all the other 49 brilliant and suggestive demonstrations." And "Industries" said (London "Electrical Review," Vol. 29, p. 193): "We have no desire to pick out weak points in such an interesting lecture, but we think that any one who read Mr. Tesla's articles must have had great difficulty in understanding his repeated idiomatic statements. Is it asking Mr. Tesla too much, holding the prominent position he does in the American electrical world,

when we say we think if he omitted some of the confusing passages his lecture would be much better understood, and if he would keep ideas anent electro-magnetic theory of light, also Hertz and Dr. Lodge from his work, his experiments would be clearer, as well as more interesting. We hope Mr. Tesla is correct when he surmises that the future light may be produced by vacuum tubes, but we believe the subject has been thoroughly searched out ere this by many inventors without a result which has been very promising." In this connection, it might be mentioned that small acknowledgment of the work of Hertz or Lodge occurs in the lectures. The ambiguity referred to in the above quotation, and certainly existing in the lectures, has been passed over in this paper, as in Tesla's case a certain lack of facility in handling English may account for what in another would seem an attempt at mystification.

Had Tesla's labors ended with these lectures perhaps he would have received less criticism in these later days. They seemed to teem with brilliant possibilities. But the applause they had evoked seems to have resolved him to keep himself before the public at all hazards. In the succeeding years each new idea or fad in the electrical world was eagerly seized upon by him and made the pretext for rushing into print, at first in the technical papers, and later, as the engineering press began to regard his effusions askance, in the non-technical daily papers, the adoption of the latter medium being accompanied with increase in sensationalism. When X rays were holding the popular attention, he dabbled in them and published his results. ("Electrical World," Vol. 27, p. 343.) When the Wehnelt interrupter attracted the interest of scientists, Tesla immediately leaped into notice. As the London "Electrical Review" says (Vol. 44, p. 653): "Tesla lets himself out on the Wehnelt interruption in the 'Electrical Review' (New York), March 15th. He invented this device two or three years ago. This belated publication in our contemporary would not, according to the generally accepted code, secure to Tesla the credit of being the inventor; but Tesla evidently does not regret this, since he considers there is not merit in the invention." And again (at p. 733): "Tesla has expressed a somewhat ungenerous contempt for the Wehnelt break, which has recently given such remarkable results in the hands of experimenters here and abroad. Its inferiority to Tesla's break appears to be known as yet only to Tesla; in simplicity, at least, it is certainly superior."

When the efforts of Marconi, Lodge and Slaby brought their first achievements in wireless telegraphy before the world Tesla had nothing but pity for their puerile efforts. When Marconi was ready to send a signal a few hundred miles, Tesla was ready (in the papers) to transmit thousands of horsepower the same distance. ("Century Magazine," June, 1900.) When Marconi was attempting to signal across the Atlantic, Tesla had already (in the papers) received a signal from Mars. (New York "Sun," Jan. 3, 1901). Before the enthusiasm over the Spanish War had had time to cool, Tesla had published a description of his torpedoes, which would revolutionize warfare. (New York "Sun," November 21, 1898.) The "Electrical Engineer" quotes the following from Tesla's signed article (at p. 514 of vol. 26): "We shall be able, availing ourselves of this advance, to send a projectile, at a much greater distance; it will not be limited in any way by weight or amount of explosive charge; we shall be able to submerge

it at command, to arrest it in its flight and call it back, and to send it out again and explode it at will; and, more than this, it will never make a miss." The editorial comment follows: "When we are expected, wide awake and in our sober senses, to accept in silence such an utterance as that quoted above, or that which describes as 'a possibility' the operation of a distant torpedo boat by the mere exercise of the will, we refuse point blank, and we are willing to face the consequences." The significance of this comment lies in the fact that this paper had always been so ardent a supporter of Mr. Tesla that it had been said to have made him and his reputation, and from the pen of its editor-in-chief had come only four years previous the greatest tribute Tesla ever received. "Inventions, Researches and Writings of Nikola Tesla," by T. C. Martin.

It was of this torpedo boat invention that Tesla said ("Criterion," November 19, 1898): "Had I nothing else to show for a life-work, this would put the laurels of everlasting fame on my head." It was of this same invention that Prof. Brackett, of Princeton, said ("Electrical Engineer," Vol. 26, p. 491): "The shortest, most correct and most complete criticism which I can make in reference to this bold boast is that, what is new about it is useless, while that which is useful had all been discovered by other scientists long before Tesla made this startling announcement." It was of this invention that Prof. Dolbear, of Tufts College, said ("Electrical Engineer," Vol. 26, p. 491): "This last so-called invention of Nikola Tesla's is a very pretentious affair, and it is so incredible that the story is not to be believed until the work is actually done. The announcement is most amazing, and, coming as it does from Tesla, scientists are all the more chary about accepting it. During the last six years he has made so many startling announcements and has performed so few of his promises that he is getting to be like the man who called 'Wolf! wolf!' until no one listened to him. Mr. Tesla has failed so often before that there is no call to believe these things until he really does them."

Lack of time and space forbids more than a passing reference to the Tesla engine which was to revolutionize steam engineering; the "discovery" of the variation of capacity with elevation, which was to necessitate the rewriting of all electrical literature ("Electrical World," Vol. 37, p. 201); the torpedo boat, which was to be manipulated at the Paris Exposition from Tesla's laboratory at New York, but which failed to appear; the Tesla oscillator, which was to enable central stations to dispense with wires ("Century Magazine," June, 1900); the method of insulation by refrigeration, which was to give the highest efficiency to transmission with wires ("Western Electrician," Vol. 27, p. 122); and even the message actually received from Mars (New York "Sun," January 3, 1901) must be passed by with merely the comment made by Prof. Fessenden ("Electrical World," Vol. 37, p. 165) that "only the crassest ignorance could attribute any such origin" to the so-called signals.

From the mass of imaginative literature that has recently issued from Tesla's ever-ready pen a single one is here selected for comment. It is chosen both because it includes a large number of Tesla's vagaries, and also because its publication in a magazine of some standing drew more attention to it than was bestowed on others appearing in the more sensational daily press.

"In the 'Century Magazine' for

June, 1900, Mr. Tesla printed a long article, superbly illustrated with cuts that had little or nothing to do with his subject, which dealt with a few electrical matters and also with philosophies and social problems, upon which he freely expressed a jumble of trivial, ignorant, pretentious and erroneous opinions." ("Popular Science Monthly," Vol. 58, p. 437.) This article attracted widespread attention, and if Tesla in truth experiences a feeling of satisfaction at adverse criticism, as he once stated in the New York "Sun," he must have enjoyed keen ecstacies on reading the comments it evoked, as the above quotation would indicate. Nor did the "Century" itself escape criticism. In publishing such pseudo-scientific productions such magazines "descend to a footing with the Sunday newspaper. They evidently do not know science from rubbish, and apparently seldom make any effort to find out the difference." ("Popular Science Monthly," July, 1900.) A brief review of the article will assist to an appreciation of the justice of the criticisms, and, perhaps, to a truer estimate of Tesla's character and the value to be put upon his work than could otherwise be obtained.

The problem treated is that of humanity as a mass acted on by forces, one tending to acceleration, the other to retardation. The three methods of increasing the energy are the increase of the mass, the diminution of the retarding force, and the increase of the force making for progress. The treatment of the first method need not be considered here. It consists merely in the assertion of well-known sociological principles. It is the second method that introduces the first novel element in this remarkable paper. War is justly considered an important factor in the retarding force, and the means of its elimination are unique. Battles will no longer be waged by human beings, but, instead, by machines, by Tesla's "telautomatons."

Rival fleets of these beneficent Frankensteins will clash in mid-ocean for the determination of maritime supremacy, their maneuvers being controlled from physicists' laboratories on shore. These long-distance weapons, the harbingers of universal peace, are already perfected. Another more wonderful type is on its way. (Quoting from the "Century" article): "An automaton may be contrived which will have its 'own mind,' and by this I mean that it will be able, independent of any operator, left entirely to itself, to perform, in response to external influences affecting its sensitive organs, a great variety of acts and operations as if it had intelligence. It will be able to follow a course laid out or to obey orders given far in advance. It will be capable of distinguishing between what it ought and what it ought not to do, and of making experiences, or, otherwise stated, of recording impressions which will definitely affect its subsequent actions. In fact, I have already conceived such a plan." Truly, Tesla's science is stranger than fiction. This noble scheme for universal peace must be passed by with a single quoted comment ("Popular Science Monthly," July, 1900): "Inasmuch as the interest in this telautomatic warfare is to be purely aesthetic, it would seem as if international bull fights or kite flying, or spelling matches, or potato races, might do as well, and have the added advantage of leaving Mr. Tesla's expectations free to wander among the following prospective discoveries."

The methods of increasing the accelerating force comprise the third and largest division of the "Century" article This section is introduced by the

wise but trite statement that all energy is derived from the sun. Three ways of manipulating this energy efficiently are suggested—the cold coal battery, direct utilization of the energy of the ether, and transmission of power through the ether. The first method is introduced by a digression on the value of iron and the wastefulness of its present production, with incidental reference to a new method of manufacture perfected by Tesla in which water is the fuel, having previously been decomposed electrolytically. This method of reduction is stated to be "cheaper than by any of the adopted methods." The digression is continued by a reference to aluminum and its prospective value to mankind. Then electric transmission is considered and the following remarkable statement appears: "Steamers and trains are still being propelled by the direct application of steam power to shafts or axles. A much greater percentage of the heat energy of the fuel could be transformed in motive energy by using, in place of the adopted marine engines and locomotives, dynamos driven by specially designed high-pressure steam or gas engines and by utilizing the electricity generated for the propulsion. A gain of 50 to 100 per cent. in the effective energy derived from the coal could be secured in this manner. It is difficult to understand why a fact so plain and obvious is not receiving more attention from engineers. In ocean steamers such an improvement would be particularly desirable, as it would do away with noise and increase materially the speed and the carrying capacity of the liners." This difficulty of Tesla's must have been cleared away by a paper of Prof. Durand's ("Marine Engineering," July, 1900), who points out that in the case of a liner of 25,000 horse power, Tesla's scheme would result in loss of about one-third of carrying capacity, besides a loss of about 2,500 horse power due to two transformations of energy, hence a loss in speed of one-half to three-quarters of a knot. As Prof. Durand remarks, "The increase of carrying capacity referred to at the close of the quotation would be, therefore, of a character not likely to commend itself to the stockholders or board of directors."

The cold coal battery itself receives scant notice. Apparently it is one of the few things Tesla has not yet perfected.

The treatment of the method of deriving energy direct from the ether contains numerous suggestions. Brief reference is made to the windmill and the solar engine. Then two perpetual motion possibilities are described. The first is a disc kept in motion by a gravity screen. A critic regrets ("Popular Science Mo.," July, 1900) that "Into further particulars concerning the nature of such a screen Mr. Tesla does not enter, though it would seem a matter well fitted to engage his peculiar gifts." The second is a perpetual heat engine, regarding which the critic just quoted says: "We should thus employ 'an ideal way of obtaining motor power' and incidentally rebuke the narrow minded physics of Carnot and Lord Kelvin." This section ends with a mention of the Tesla mechanical oscillator and a reference to liquid air.

The third and last method, that of utilizing the ether as a bus bar, is stated to find greatest favor in the author's eyes. Mention is made of his experiments with one wire and with none, with wobbling the earth's charge and with electrifying the upper strata of the atmosphere. The secret of tuning for wireless transmission is revealed and the errors of the experiments of Hertz pointed out. The possibility of signaling to Mars is asserted, and the facts of

power transmission are stated as follows: "The experiments have shown conclusively that, with two terminals maintained at an elevation of not more than 30,000 to 35,000 feet above the sea level, and with an electric pressure of 15,000,000 to 20,000,000 volts, the energy of thousands of horse power can be transmitted over distances which may be hundreds and, if necessary, thousands of miles." No data as to methods of ballooning or of supporting wires at this elevation are given. Instead, the article closes with a quotation from Goethe. This quotation, with its reference to fulfilment, furnishes a most strikingly complete and sarcastic, though evidently unconscious, comment on the whole ludicrous production.

A perusal of the article forces one to coincide with the verdict of "Marine Engineering," whose editor describes it ("Marine Engineering," July, 1900) as the "handiwork of a cerebrose individual —a bombastical genius who has illumined unknown fields of imaginative science with his intellectual searchlight, and is willing to permit the gaping world of ignorance or complaisance to peep in and wonder, the credulous editor drawing the curtain. This dazzling contribution to modern unscientific research reads like nothing so much as an essay on Christian Science, so profound is it in the ambiguous nothingness whereby it leads through the intricacies of incoherency into the climax of absolute assininity."

Enough has been given to indicate the reason for the standing that is Tesla's today in the scientific world. Not even the brilliancy of suggestion and experiment contained in his early work, not even the persistent efforts of powerful friends, moved by their commercial interests to magnify and exalt the value of his patented inventions, could avert the discredit to his reputation as a scientist brought upon himself by his wild struggles for notoriety He has been condemned by his own extravagant boasts, never followed by the realization of their claims and often revealing a total misunderstanding of the very elements of physical laws.

Tesla is still a young man, and those whose sympathetic expectation was aroused by his early work still hope that he will turn from the gaudy notoriety of the Sunday newspaper, and by conscientious work give at last one complete useful invention that may be honestly set to his credit, and that may make its influence felt on the progress of engineering science.

NOTES.

THE second Paper deals with Prof. BRAUN'S apparatus for military signalling. Here, in a remarkably portable form, is arranged powerful apparatus capable of operating without the earthing of the air-wire across a distance of 50 miles on land. A 5 H.P. benzine engine drives a dynamo whose current is transformed to yield a 16in. spark. This spark occurs between balls in the primary circuit of a Tesla coil. The air-wire, suspended by balloon, is in series with the secondary of the Tesla transformer; but, instead of being earthed, it is connected to a large insulated plate. The generating plant is virtually a Poldhu in miniature. Evidently, BRAUN, like MARCONI, has been converted to the high potential methods introduced by TESLA. BRAUN has freed himself from the earth, however, and has thus produced a system endowed to the fullest with that mobility so urgently demanded in modern warfare.

WIRELESS TELEGRAPHY FOR MILITARY PURPOSES.*

BY ARTHUR WILKE.

The first experiments in the use of wireless telegraphy for military purposes were in the Boer war, but these met with little success, and it is possible that for this reason interest in wireless telegraphy for such purpose has somewhat abated. By means of the Braun system, however, the German army authorities, in conjunction with the Braun and Siemens and Halske Wireless Telegraph Co., have succeeded in developing a useful system of wireless telegraphy for the German army, and have constructed portable stations which can communicate with one another with certainty over distances up to 100km.

Owing to topographical considerations the transmission of Hertzian waves over land is extremely difficult unless an extremely high air-wire is employed. This requisite for a successful system has been provided for by the balloon section of the German army, under which the wireless telegraph department was placed. The air-wire, which is a fine steel wire, is elevated by a small balloon held captive by the wire itself, or, if the conditions are favourable, by a kite. I will first shortly sketch the Braun wireless principle and the form it takes for field wireless telegraphy in the German army. First, the difference between an open and closed oscillating circuit must be explained, and this explanation will be a technical one and differs to some extent in this form from the theoretical one which Prof. Braun has given.

Let us consider a positive quantity of electricity on one-half, *oa*, Fig. 1, of a wire so collected that the pressure grows towards one end of the wire, and in the same manner an equal quantity of negative electricity on the other half of the wire *ob*. Let the curve above and below the wire represent the pressure at each point. This distribution represents that of a stationary electric wave at one moment of the oscillation. It is now evident that the action which the one

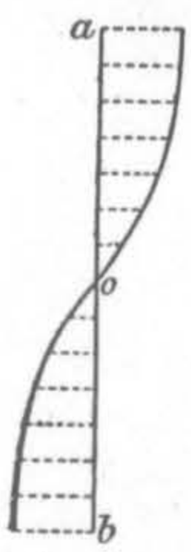

FIG. 1.

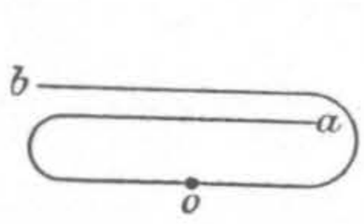

FIG. 2.

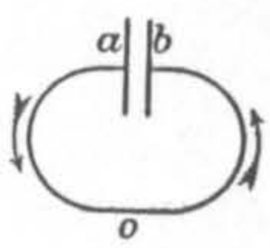

FIG. 3.

quantity of electricity exerts upon the other will be a minimum in this arrangement. In the same way the capacity possible for a good conductor will also be a minimum. Such a conductor thus absorbs the relatively smallest amount of energy. Further, the two quantities of electricity in such a conductor will annul themselves in relatively the quickest time, and the highest discharge currents will be developed. Now, let us consider further the straight form of conductor. If the conductor discharges itself with the distribution of electricity shown in Fig. 1, a current flows from *a* to *b*. Thus waves will be emitted radially in all directions from the whole length of the wires. It is thus clear that the emitting capacity of such an oscillating conductor will be the maximum. With this kind of oscillating conductor in which the charges are subject to the smallest mutual effect on one another—viz., in an open oscillating circuit, as we will now call it, we have the maximum absorption of energy and the maximum emitting capacity. Now, if we have the wire *aob* and bend it in the form shown in Fig. 2, the discharges on both ends of the wire will influence one another. Thus the oscillating circuit assumes another character whose properties will be clearer to us, if we bring the charges of the two ends of the wire to two plates which are placed opposite one another, and are connected by a wire as shown in Fig. 3. By this arrangement the capacity of the conductor will be considerably increased. The relative amount of energy is a maximum to this closed oscillating circuit. Now, the conductor *aob* will likewise omit waves, but considered geometrically the direction of the current in *ao* is opposed to that in *ob*, so the effects of the two halves cancel out, either entirely or to a certain extent. The closed oscillating circuit is, therefore, of no use for transmitting. Its emitting capacity can, in addition, be diminished at will, for the connecting wire *aob* can be shortened down to the very smallest length. Thus it happens that the closed oscillating circuit can absorb a great quantity of electrical energy, and can maintain a condition of oscillation for a comparatively very long time, as the losses by radiation and by resistance can be diminished by shortening the conductor *aob* considerably. The closed oscillating circuit is thus the form for the excitation of strong oscillations and successions of waves. As it further admits of a very accurate tuning, the generation of pure and accurately tuned oscillations are possible. The open oscillating circuit is without all these advantages, but in place of them, as has already been said, it possesses what is absent in the closed oscillating circuit—viz., a high degree of emitting capacity.

Thus Braun's conclusions are as follows:—If one wishes to obtain a powerful transmitting action, the waves should be generated in a closed oscillating circuit, and then conveyed to an open oscillating circuit for transmitting. Then we are in a position to send out long, persistent and pure successions of waves, and thus increase the

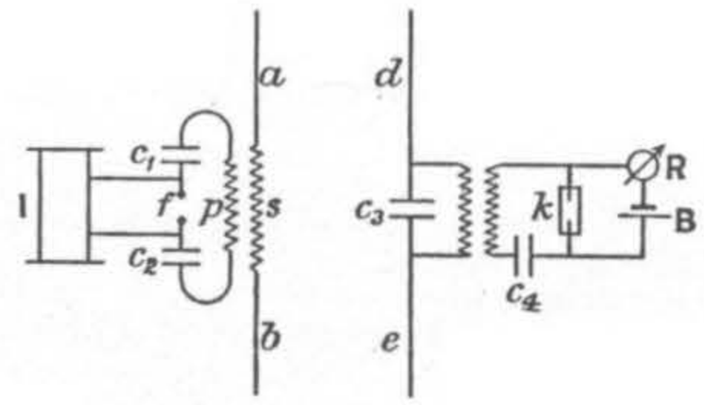

FIG. 4.

amount of energy sent out, and tune the apparatus to a given wave-length. Here it must also be observed that the powerful closed oscillating circuit can force its oscillations upon the open oscillating circuit connected to it, even if the latter has another period of its own. The open oscillating circuit must oscillate in tune with the closed one, and its own period is only the effect of a slight superposition or light ripple on the main wave. What has here been said about the transmission applies to the same extent to the receiving apparatus. The open form of oscillating circuit is the one provided to receive the energy from the incoming waves. If used alone, however, it would quickly be saturated. By connecting it with the large reservoir which the closed oscillating circuit affords, it can lead the received energy directly to the latter, and is thus ready to receive more. Thus, by a combination of the open and closed oscillating

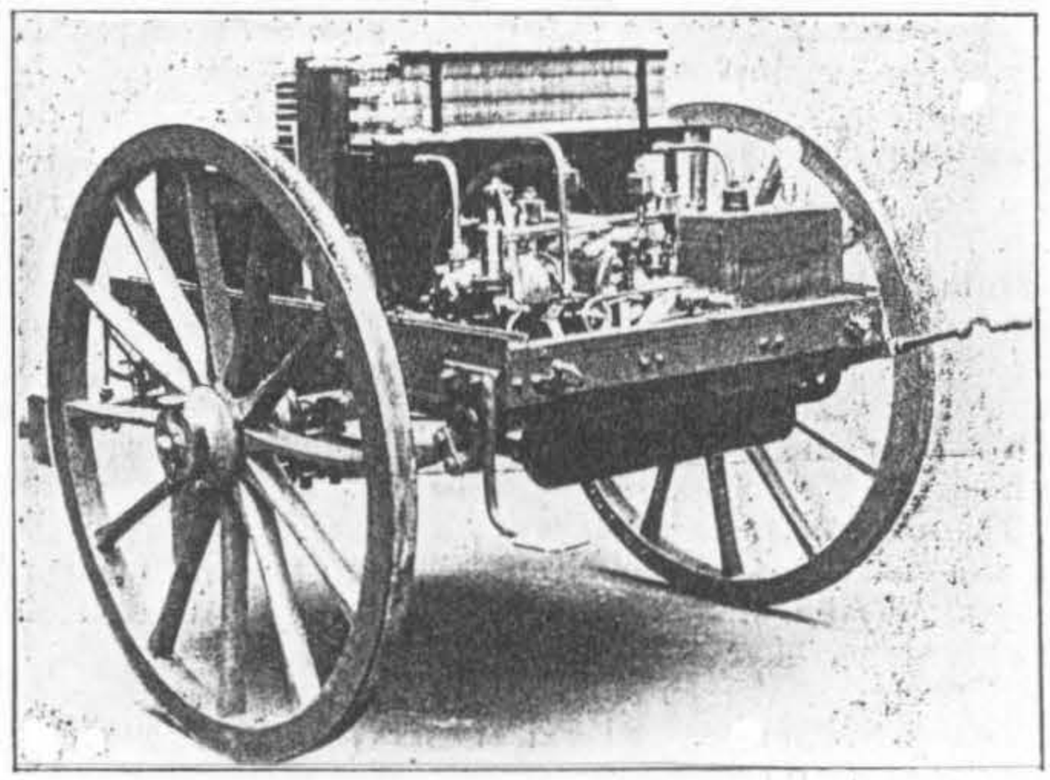

FIG. 5.—BENZINE MOTOR ON THE REAR CARRIAGE.

circuits, the receiving station can receive the maximum of energy from the waves. For good transmission over long distances it is also of governing importance that the coherer shall have as much energy as possible led to it, so that an increase in the quantity of energy received means an increase in the distance over which it can be transmitted.

It may be remarked that in the application of this system to field wireless telegraphy, owing, on the one hand, to the length of the wire attached to the kite, or, on the other hand, to the fact that this wire must be very thin, to save weight, the good, but also the bad, properties of the open oscillating circuit are evidenced to a much greater extent than with the air-wire arrangements with ordinary

* Abstract of an article in the *Elektrotechnische Zeitschrift* for January 15, 1903.

fixed stations, and, therefore, in this case, the use of a closed circuit as an auxiliary is particularly important.

Fig. 4 shows diagramatically the connections employed. I is the induction coil, whose secondary coil is connected to the spark-gap *f* The spark-gap is also connected into the oscillating circuit which is formed by the condenser c_1, the connecting wire, and the condenser c_2. In this circuit the primary winding *p* of a transformer is also included. It may be observed that connecting two condensers in the oscillating circuit in place of the single one shown in Fig. 3, implies no alteration in the principle. The rapidly oscillating alternating currents produced in the closed oscillating circuit act inductively on the secondary winding *s* of the transformer to which the straight wires *a* and *b* are connected. These wires have such dimensions that each is a quarter wave-length in length, corresponding to the period of oscillation obtained in the closed oscillating circuit. On *a* and *b*, therefore, stationary waves of opposite nature will be formed whose maxima will be at the ends of *a* and *b*. The electrical condition in the open oscillating circuit *asb* is thus balanced. At any moment there will be equal and opposite quantities of electricity on the two halves *as* and *sb*. The open oscillating circuit of the Braun arrangement, therefore, needs no earth connection, and it will at once be recognised what an advantage this is for portable stations. The inductive transmission of the oscillations of the closed circuit to the open circuit can be replaced by direct conduction, and Braun speaks of a direct and indirect (inductive) connection which are, however, the same in principle. Now, one could extend the two halves of the open oscillating circuit above one another in the air, as in Fig. 4; but it is at once evident that the transformer would then have to be placed in the middle of the air-wire. It is possible, however, to keep the transformer below at the station, and employ the half *sb* in another form to serve as a balancing conductor. This half of the conductor can be replaced by an insulated metal plate.

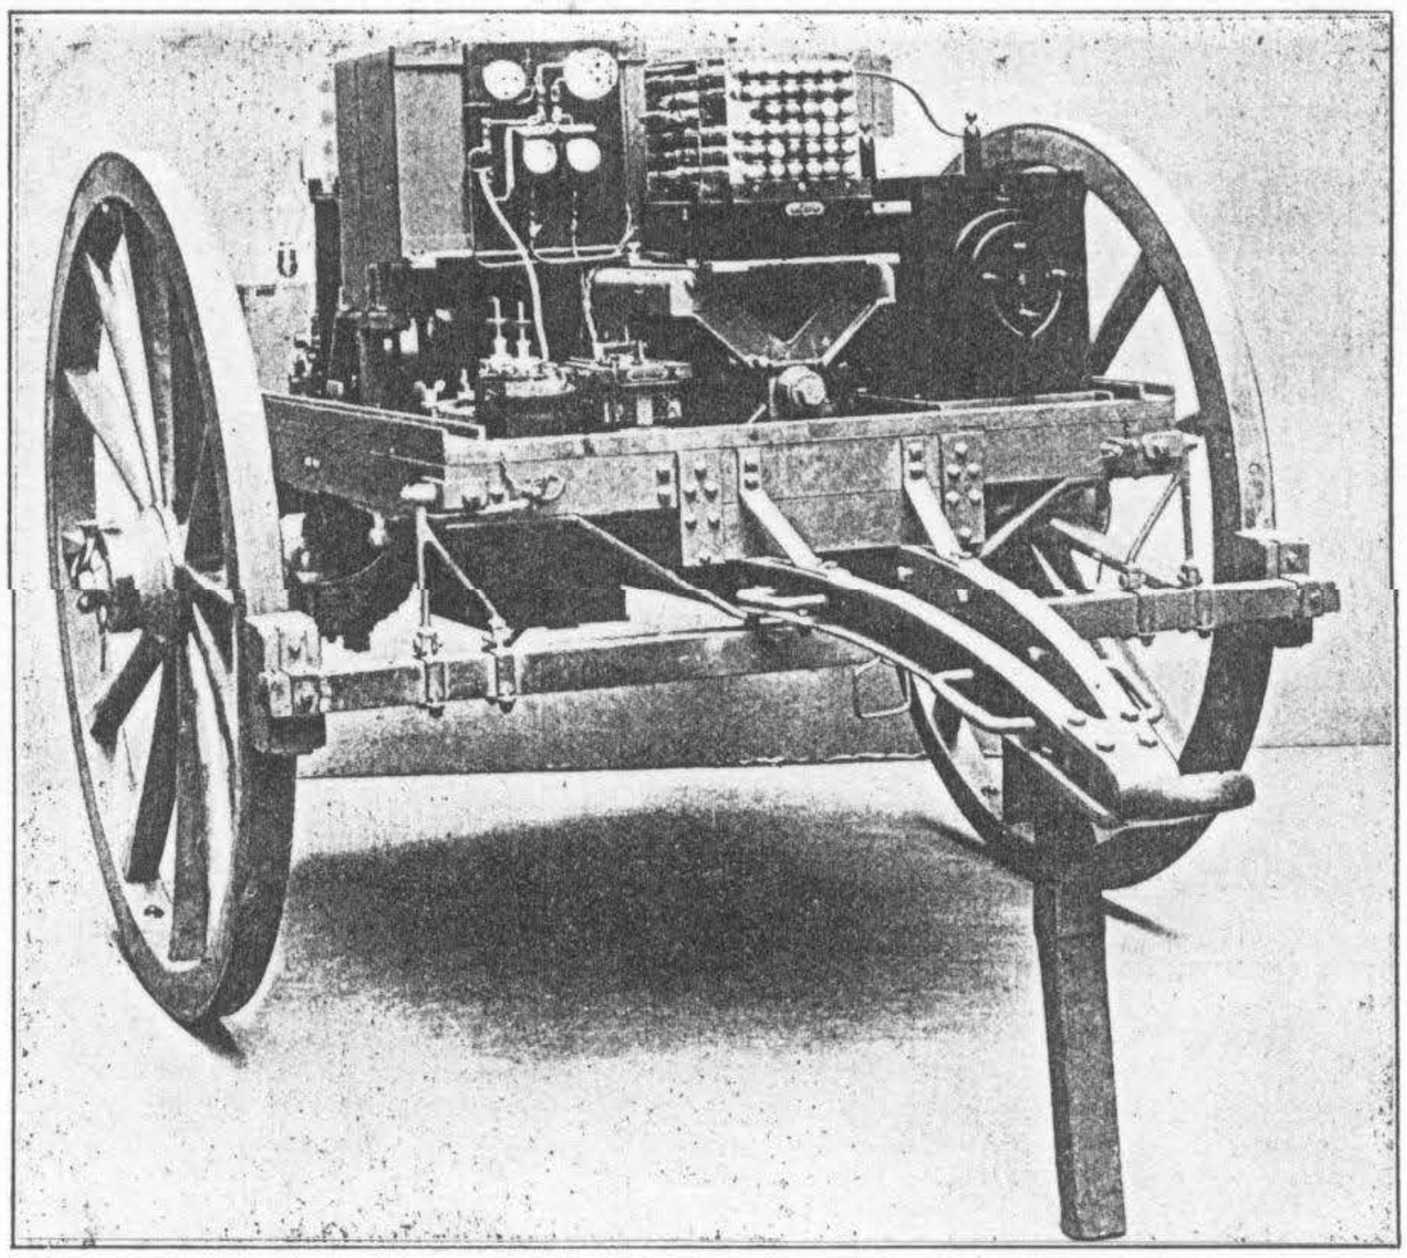

FIG. 6.—DYNAMO AND TRANSMITTER.

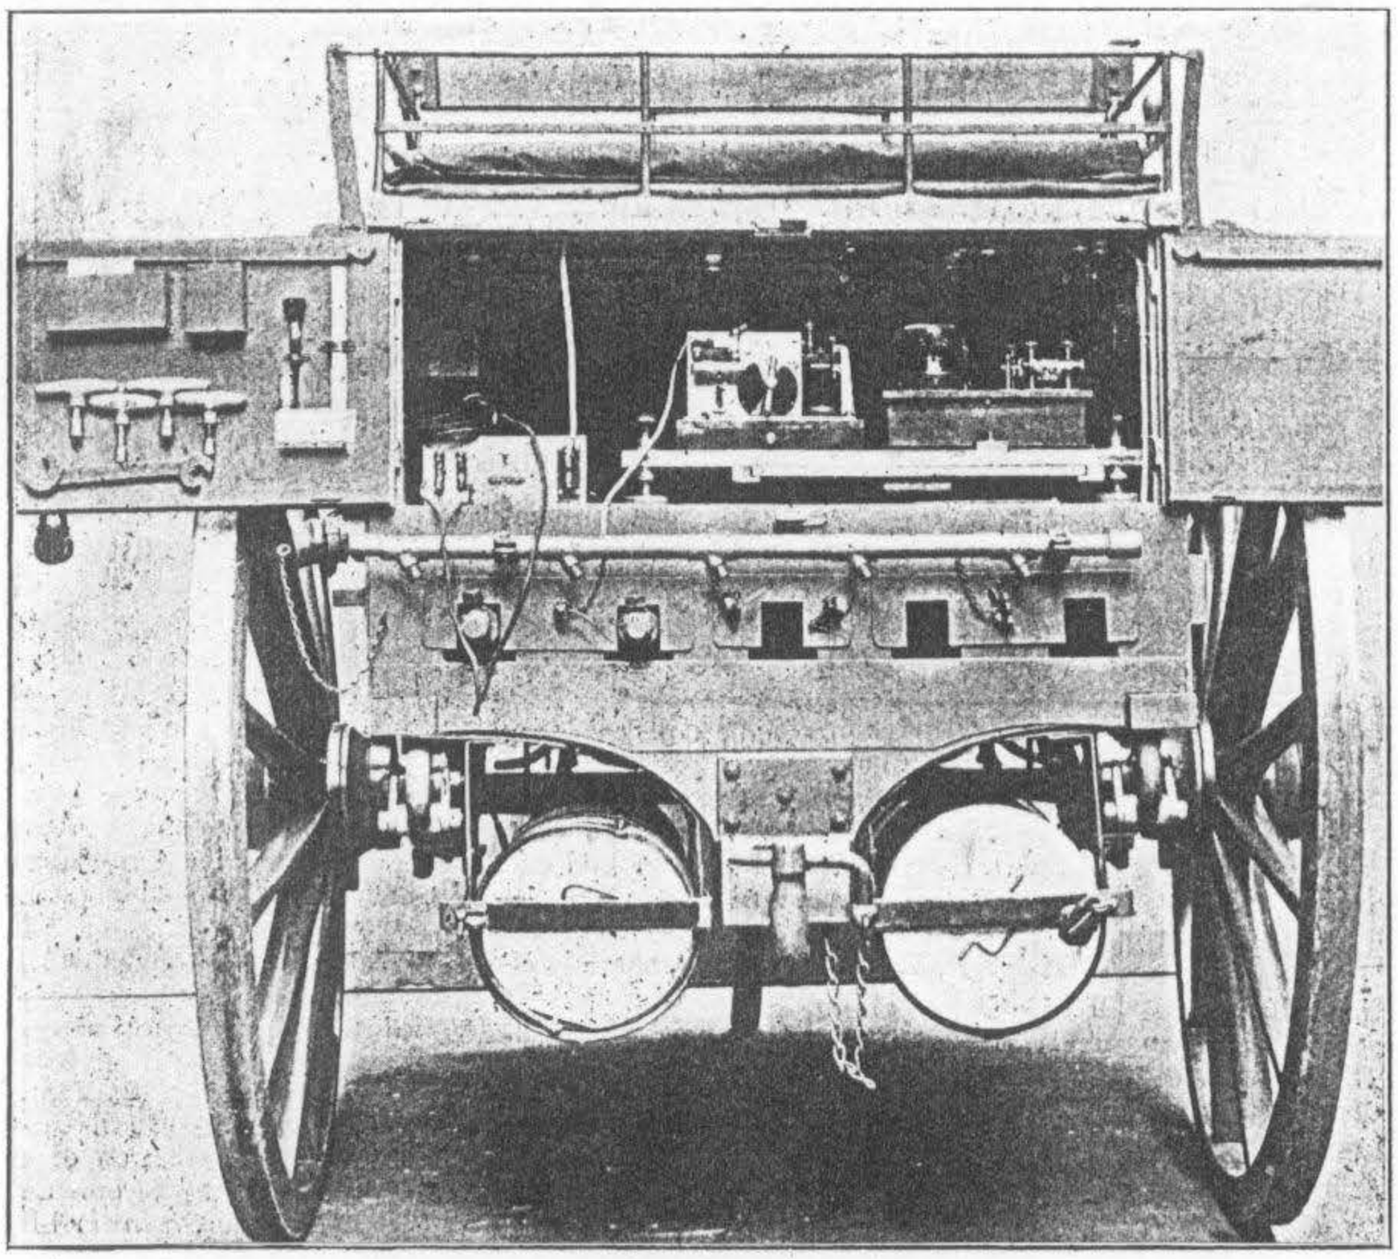

FIG. 7.—FRONT CARRIAGE WITH RECEIVER.

The actual apparatus as used in field wireless telegraphy is divided into two halves: one for the production of current and the oscillations, and thus for transmission; the other for receiving. Each half is carried on a two-wheeled cart, and the two carts are coupled together, as seen in Fig. 8. Fig. 9 shows the two carts disconnected and in actual work. As in these illustrations only the external appearance of the carts is seen, Figs. 5, 6 and 7 are added, showing the disposition of the apparatus in the carts. In Figs. 5 and 6 the transmitting plant is seen. This consists of a 5 H P. benzine motor driving a dynamo at 800 revs. per min. The benzine motor is seen in Fig. 5, and the dynamo can be distinguished in Fig. 6. This generates 2·5kw. at a pressure of 120 volts. This method of generating current is the only one that could be applied, as for military reasons the employment of dry batteries or accumulators would not be possible. To the right of the dynamo in Fig. 6 is the series resistance, which is contained in a wooden box. In the pipe leading to the cooler of the benzine motor, a small pump is connected, whch is driven by the motor shaft and circulates the cooling water. To the left of the dynamo in Fig. 6 is the induction coil, which is designed for a sparking distance of 40cm., and on the dividing wall between the front and back of the cart and to the back of the cooler is a small switchboard with an ammeter and voltmeter. Between the switchboard and the induction coil over the dynamo the Leyden jar circuit is fixed. This circuit is the part of the apparatus which we call the condensers, c_1 and c_2, in Fig. 4. It consists of 40 Leyden jars, each 30cm. long, with an external diameter of 2·5cm. The two batteries formed in this manner are then connected in the closed oscillating circuit, as shown diagrammatically in Fig. 4. The capacity of the double battery is 0·01 microfarad, and this is not altered. Such an oscillating circuit produces many hundred—up to 1,000—single waves for each spark, while the sequence of waves of the open oscillating circuit may be as little as one or a few dozen oscillations. There is little to say about the front carriage, shown open in Fig. 7. Each carries a receiving apparatus. To the right is the coherer, with its relay, and next to these the Morse ink-writer. For the relay circuit, as well as for the Morse ink-writer circuit, Hellessen dry cells are used. Particular attention has been paid to ensure high insulation

both for the receiver and transmitter, and tests have shown that absolute certainty of working may be obtained in the worst weather. The containers for the hydrogen gas used for filling the balloon are placed under the body of the front cart. In addition to this, the balloons themselves, kites, and the various material necessary for military purposes are carried on the carts. Each pair of carts is accompanied by one officer, one non-commissioned officer and five men in addition to the driver. The apparatus was used with success during the German manœuvres last year, and was employed to transmit the most important news. Various distances of transmission were successfully overcome. In general, the distance was from 40km. to 50km., but in some cases it was over 60km. and up to 80km. It is evident that these distances are not the ultimate limits of wireless telegraphy over land.

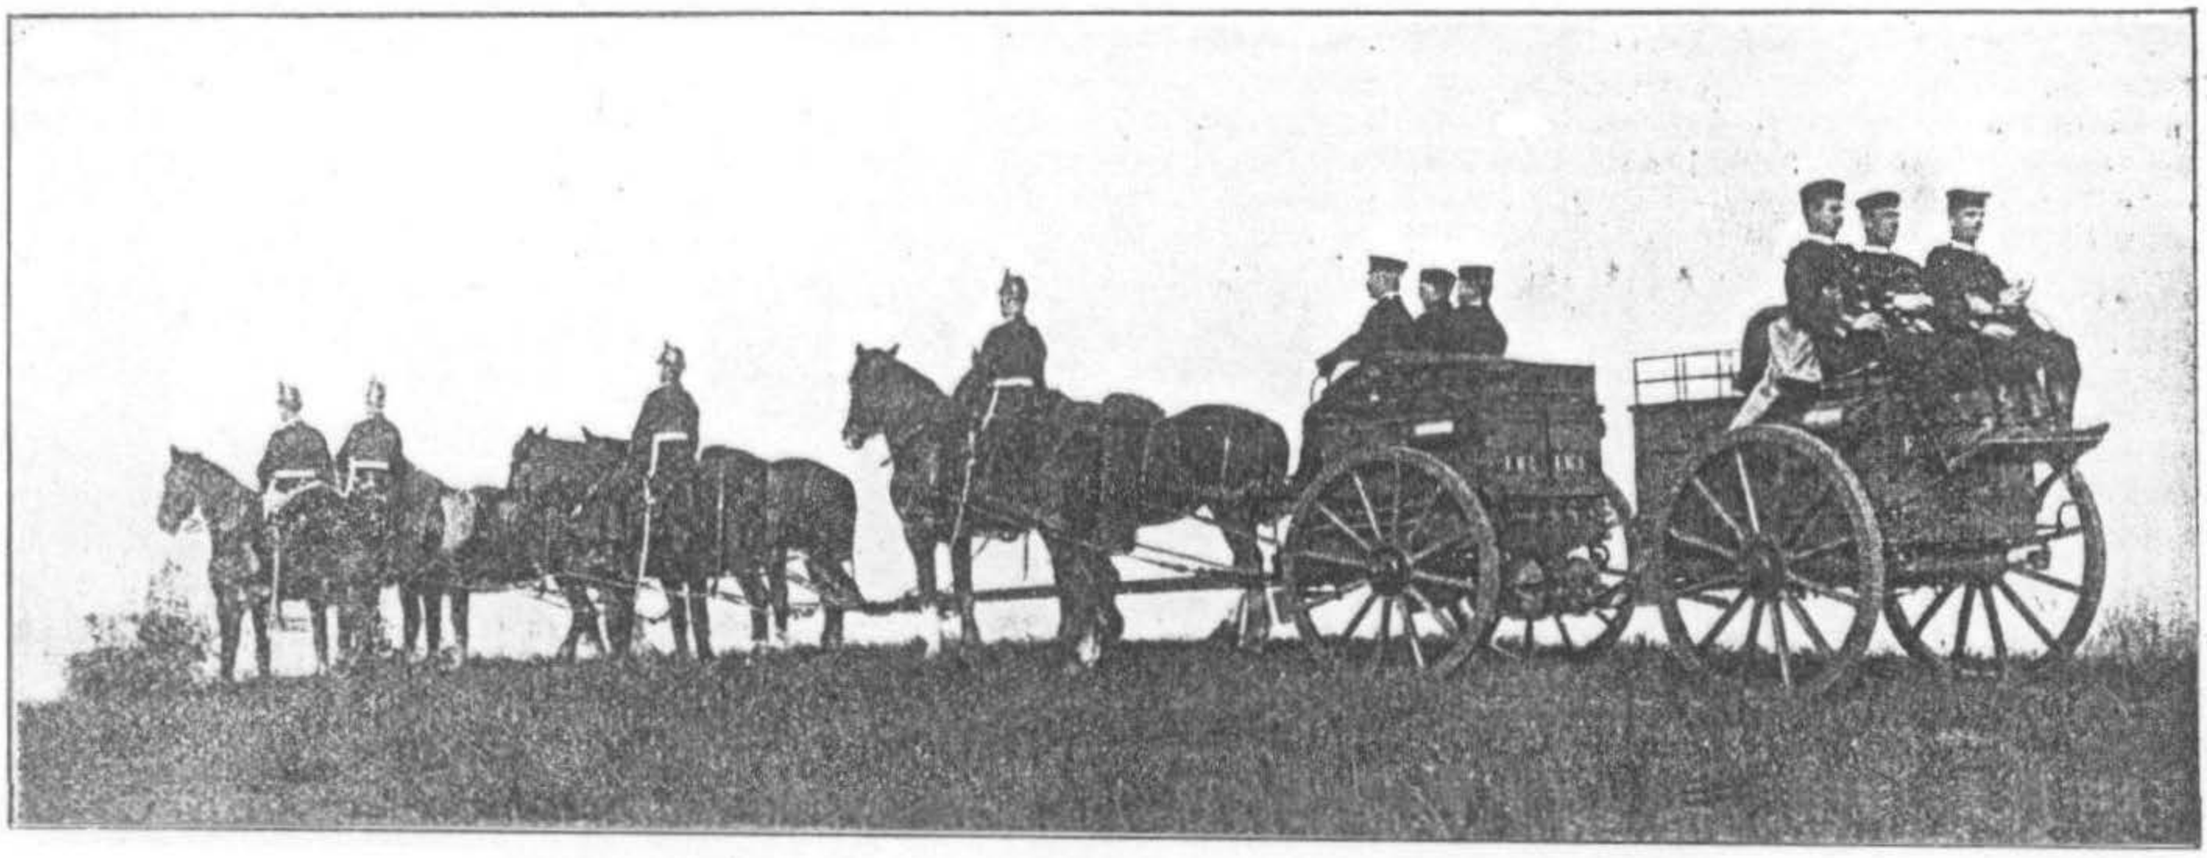

FIG. 8.—FIELD WIRELESS TELEGRAPH APPARATUS READY TO TAKE THE FIELD.

FIG. 9.—APPARATUS READY FOR OPERATION.

Tesla Split-phase Patents Not Infringed.

Meter manufacturers and electrical men generally are greatly interested in the litigation based on the Tesla split-phase patents. On February 26th, by a decision handed down in New York city, the United States Circuit Court of Appeals for the Second Circuit reversed the decision of the court below and declared that invention by Tesla prior to April 22, 1888, had not been proved, thus deciding against the patents and in favor of the defendant. The case was that of the Westinghouse Electric and Manufacturing Company, appellee and owner of the patents, against the Catskill (N. Y.) Illuminating and Power Company, appellant, which was a user of the well-known Scheeffer meter, the device complained of as infringing the patents. The manufacturer of this meter, the Diamond Meter Company of Peoria, was the real defendant, and is receiving congratulations on the strong and successful defense made on its behalf.

The opinion of the court in this important case was written by Judge Townsend, Judges Wallace and Coxe concurring. It is as follows:

Appeal by defendant in the court below from its decree on bill alleging infringement of complainant's patents, Nos. 511,559 and 511,560, granted to Nikola Tesla on December 26, 1893. The court below sustained both patents and found infringement of both claims of patent No. 511,559 and of the first claim of patent No. 511,560.

Inasmuch as we have reached a conclusion adverse to the complainant upon the question of priority of invention, the other issues will not be discussed.

The claims of patent No. 511,559 are as follows:

"1. The method of operating motors having independent energizing circuits, as herein set forth, which consists in passing alternating currents through both of the said circuits and retarding the phases of the current in one circuit to a greater or less extent than in the other.

"2. The method of operating motors having independent energizing circuits, as herein set forth, which consists in directing an alternating current from a single source through both circuits of the motor and varying or modifying the relative resistance or self-induction of the motor circuits and thereby producing in the currents differences of phase, as set forth."

The first claim of No. 511,560 is as follows:

"1. The combination with a source of alternating currents, and a circuit from the same, of a motor having independent energizing circuits connected with the said circuit, and means for rendering the magnetic effects due to said energizing circuits of different phase, and an armature within the influence of said energizing circuits."

The claims of the former patent cover a certain method, and of the latter certain means of operating electrical motors by means of alternating currents from a single original source. This system is known as the "split-phase" system.

Nikola Tesla, the patentee herein, was the inventor of what is known as the polyphase system of transmission of power, and had covered by his earlier patents, Nos. 381,968, 382,279 and 382,280, said system when operated by means of currents of varying phase from independent lines or circuits. The applications for these earlier patents were filed during the fall and winter of 1887, and the winter and spring of 1888, the final fees were mailed on April 8, 1888, and said patents issued May 1, 1888.

Up to April 8th Tesla had not intimated to his solicitor that his broad invention of the rotary-field motor could be practiced by any means which did not involve the use of two independent circuits from the generator to the motor.

The applications for the patents in suit were filed December 8, 1888. By the method and means therein described Tesla dispensed with one of the line circuits and was able to run the motor by means of alternating currents from a single original source. This was accomplished, as appears from the foregoing claims, by means which so retarded the phases of the current in all circuits or so varied the relative resistance of the motor circuits as to maintain the necessary difference of phase in the currents. Such utilization of a single original source by thus splitting a single current into two currents, was an improvement of great practical value.

But on April 22, 1888, there had been published at Milan, in an Italian journal, a report of a lecture by Professor Galileo Ferraris, in which the system covered by the patents in suit was fully described. This printed publication is such a disclosure of the subject-matter of the patents in suit that if prior thereto would constitute an anticipation.

To support the burden thus cast upon it of proving to the satisfaction of the court that the supposed inventions in suit were made prior to April 22, 1888, complainant has introduced a photograph and the evidence of two witnesses, Messrs. Brown and Page. One of said witnesses has testified that said photograph represented a motor which was in Tesla's shop in the fall of 1887, and in which the difference in phase was secured by the introduction in one of the circuits of a coil having self-induction. There is nothing in the photograph, however, to indicate the means by which said motor was operated, nor whether it was adapted to receive a single or double current from the generator. Its construction is at least as suggestive of use in connection with the earlier polyphase as with the latter split-phase patents. We are, therefore, confined to a consideration of the testimony of said two witnesses.

Mr. Brown furnished capital to Tesla to make his experiments at the date here in question, and afterward sold his interest in the Tesla inventions to this complainant. On May 25, 1900, he testified that in 1887 Tesla disclosed to him certain inventions made by him relating to split-phase alternating-current motors and showed him such motors in operation in his shop in Liberty Street (in 1887), and that the shop was afterward moved and destroyed by fire, and he thought all the motors were destroyed in said fire. He further stated that he had had no experience with alternating currents beyond that which he had had through his connection with Tesla. He failed to identify the date of the disclosure or to account for the loss of said motors further than as hereinbefore shown, and complicated his vague general description of said apparatus by contradictory statements as to the specific means used in their operation. But, apart from all this, he failed to so describe the said apparatus that this court can determine whether they did, in fact, embody in structure and practical operation the specific form of apparatus used by the defendant. Such evidence, under the familiar rule, called either for corroboration or for some explanation why corroboration was impossible.

The complainant failed to comply with said rule. It failed to show that Tesla alone constructed said motors, or to produce anyone employed in said shop in 1887 who might have seen said motors or taken part in their construction, or to account for their absence. It failed to put Tesla himself, a resident of New York, on the stand to show to the court the precise nature of the inventions disclosed and practiced by him in 1887.

Farther than this, other uncontradicted testimony strongly tends to show that the witness must have been mistaken as to the date of this disclosure and of the operation of said motors. It appears that in 1888 Tesla spent nearly two weeks at the factory of the Mather Electric Company, explaining his new alternating-current motor inventions, with a view to interesting said company in their development and manufacture; that one of the objections made to their operation was the fact that they required a special generator and extra wires, but that Mr. Tesla did not then claim that he had made any invention whereby two currents of different phase could be derived from a single source. Again, complainant's other witness to the date of invention, Page, who was Tesla's attorney, and who, during 1887 and 1888, prepared the Tesla applications for the polyphase and other patents, including those here in suit, testified that up to a few days after April 8, 1888, "Mr. Tesla had never intimated in any way to me that his invention of the rotary-field motor could be practiced by any means which did not involve the use of two independent circuits from the generator to the motor."

We are forced to the conclusion that Brown, testifying at this distance of 13 years, must have had in mind the year 1888, during which year also, as he testifies, he saw said motors in said shop.

We are brought, then, to a consideration of the testimony of said Page, the witness chiefly relied on to carry the date of invention back of April 22, 1888. The material parts of his testimony are as follows, namely, that having been employed as aforesaid, Tesla "explained that he had other ideas about the operation of these motors, and thereupon disclosed to me his scheme for operating the motors by connecting them with single circuits; that when he first described the scheme of patent 555,190 (application filed May 15, 1888), Mr. Tesla also described to me the plan of operating these motors which involves the splitting of a circuit, * * * upon which patent 511,560, which is one of the patents in suit, is based; and that I understood fully from his description, not only the principal and essential features of the inventions involved in the patents in suit, but also another plan which he had at that time developed for effecting the same result by making the poles of a motor of different magnetic susceptibility, * * * the subject of an application filed October 20, 1888, and which became patent No. 524,426."

It further appeared on the hearing in this court that Mr. Page filed three other Tesla applications on April 23, 24, and 25, 1888, respectively, and which issued in October, 1888, as patents Nos. 390,414, 390,820 and 390,721, respectively. Neither these patents nor Nos. 555,190 and 524,426 are in suit herein. Some of the patents cover modifications of the polyphase, others of the split-phase invention. The applications which resulted in the patents in suit were not filed until December 8, 1888. As to the character and date of said disclosures, the witness further testified as follows:

"I cannot say, from present recollection, how many of the specific arrangements for producing artificially the necessary differences of phase which are described in the two patents in suit Mr. Tesla described to me in the early part of April, 1888, but my recollection is clear to the fact that between April 8, and April 18, 1888, on which latter date I entered a charge in my diary for services in this particular matter."

The diary was not produced. The witness stated: "I had occasion several years ago to look up the facts in connection with the matter about which I have just testified, and at that time I had this book in my possession;" that he then used it in giving certain testimony; that he had since searched for it, but had been unable to find it; and that his present testimony was based upon his recollection of the matter and upon the records of previous testimony given on this point.

This evidence is clear, direct and persuasive as to a disclosure by Tesla of various schemes for operating motors on the split-phase principle. But it falls far short of the requirement in such a case.

"The burden which rested upon the defendant in the first instance has been transferred to the complainant, and it must furnish the court with convincing proof that the anticipation has been anticipated." (The Westinghouse Electric and Manufacturing Company v. Saranac Lake Electric Light Company, 108 Fed., 221, 222; Clark Thread Company v. Willimantic Linen Company, 140 U. S., 481.)

It is to be noted that this testimony relates to events which occurred 12 years before; that the only means which the witness had for refreshing his recollection is the lost diary. The witness could not be expected to have any independent recollection as to what was covered by the charge, entered four days before the date of the anticipating publication, for "services in this particular matter," nor whether the date and character of said charge was correctly entered. The evidence fails to show the specific character of said disclosure, whether it covered the constructions herein held to be infringed or some of the other constructions embraced in the patents in suit or in said other patents not in suit on which the witness was then engaged. Nor does it appear with satisfactory definiteness that the disclosure was a sufficiently full and complete disclosure of the particular claims involved herein, or, if so, which were thus disclosed. The witness does not state what Tesla said to him. Apparently, all that he learned from Tesla was the "principal and essential features of the inventions involved in the patents in suit."

The fact that the applications for the patents in suit were not filed until December 8, 1888, while said applications for other specific phases of said invention were filed on May 15th and October 20th, tends to support the claim that the "particular services" were rendered in regard to said earlier specific inventions and that Tesla did not perfect and complete the inventions in suit until a later date.

In these circumstances it was incumbent upon complainant to furnish additional evidence in order to remove these uncertainties or to account for its failure so to do. No attempt was made, however, to further fix the date or character of Page's services, either by the books of his firm, the bills rendered, the testimony of his partners or of his Washington associates, with both of whom he consulted, or by the date of the trip taken to Washington in regard to the matter, or by the testimony of Tesla himself. Complainant has failed to comply with the fundamental rule that the best evidence of which the case is, in itself, susceptible, must be produced.

In these circumstances we are constrained to hold that invention by Tesla prior to April 22, 1888, has not been proved.

The decree is reversed with costs and with instructions to the court below to dismiss the bill with costs.

Charles A. Brown, the well-known patent lawyer of Chicago, in commenting on the decision for the benefit of the readers of the Western Electrician, expressed himself as follows:

"The patents involved in this suit are known as the Tesla split-phase patents. The claims which are quoted in the opinion of the court show that the patents are very broad in their apparent scope—so broad, in fact, that unless limited to the particular mode of operation of the so-called Tesla rotating field, they are anticipated by many devices of the prior art.

"The anticipating reference on which the Tesla patents were found to be invalid by the Circuit Court of Appeals was the well-known Ferraris publication. Ferraris' lecture, which fully described the construction and mode of operation set forth in the Tesla patents, was delivered in Turin on the 16th of March, 1888. Publication of this lecture occurred in the Italian journal l'Eletricitta, April 22, 1888, and other technical journals in Europe and America published the lecture soon afterward. Shallenberger and others also made the improvements set forth in the patents independently of Tesla, and before December 8, 1888, the date of filing the applications for the patents under consideration.

"As the court's opinion shows, it was necessary for complainant to establish a date for Tesla's invention earlier than April 22, 1888, and to do this clearly. The failure to do this was fatal to complainant's case and to the patents.

"Tesla's claim was based solely upon a legal technicality. He was not in any case the one who gave the split-phase motor to the world. Ferraris did that. Not only was the Ferraris publication earlier, but he undoubtedly made the improvement actually long before Tesla thought of it. Tesla could get no patents in Europe on account of Ferraris' work. But in this country, under our laws, the use of an improvement in a foreign country does not anticipate an invention. It is the publication that counts as an anticipation in such a case. It was upon this legal technicality that the Tesla patents were based. The Westinghouse company bought the Ferraris rights in this country.

"An interesting fact in connection with this matter is not referred to in the opinion of the court. In

the latter part of February, 1888, Tesla went to Manchester, Conn., to show his rotating-field motors (it was Ferraris, by the way, and not Tesla, who gave the name 'rotating field' to these motors) to Professor Anthony, with a view of getting a report from him. When Professor Anthony saw and understood the polyphase motor, he promptly thought of operating the motor on a split-phase circuit, and he wrote to his friend, Dugald C. Jackson, now professor of electrical engineering in the University of Wisconsin, explaining both the polyphase and split-phase modes of operation. Professor Jackson replied, giving descriptions of other ways of operating the rotating-field motor. It was some nine months later that Tesla applied for patents showing precisely the plans and methods of operation set forth in this correspondence between Professor Anthony and Professor Jackson. The patents thus applied for are those which have just been declared invalid by the Circuit Court of Appeals.

"The point upon which the decision turns lies at the threshold of the defense in this case. That other and serious defenses were presented may be appreciated from the fact that the record comprises between 2,300 and 2,400 printed pages."

What Mr. Tesla Is Said to Have Said.

In a floating newspaper paragraph Nikola Tesla is thus reported: "The wireless telegraphy plants you may have seen are but networks of flimsy wire. We are not doing anything of that sort here at Wardenclyffe. We are building for the future. It will be some time before our preparations are complete, but when we are ready we will be able to accomplish what we desire. We shall not be handling a plaything. It will be something for business. I do not believe that messages can be transmitted without wires for more than 50 or 60 miles without the use of the principles which I have patented throughout the civilized countries of the world. By the use of my system you will be able to put an instrument in your house and talk to anyone who has a similar apparatus anywhere in the country without any metallic or artificial connection."

The New York Sun March 15, 1903

DIFFER OVER TESLA METERS.

U. S. Court in One Circuit Upholds His Patents, in Another Does Not.

Judge Cult, in the United States Circuit Court for the First Judicial district, which includes Maine, Vermont and Massachusetts, handed down a decision Thursday in the case of the Westinghouse Electric Manufacturing Company against the Stanley Instrument Company of Great Barrington, Mass. The suit was brought to restrain the Stanley company in its principal business, manufacturing electric meters, which, it was alleged, Nicola Tesla had invented and the patents on which the Westinghouse Company owns.

The decision was in favor of the Stanley Company, the court holding that the plaintiffs had not satisfactorily established Tesla's priority of invention over that of an Italian of the name of Galileo Ferraris Tesla asserted that he had, in April, 1887 taken out letters patent on a meter of the particular "phase" of the one in litigation The Stanley company asserted that he had simply patented in this country the device of the Italian inventor.

Several years ago Tesla's labratory took fire and all the records of earlier inventions were destroyed. Therefore direct proof of the plaintiff's contention was wanting. On the proof which was adduced before Judge Cult, however, the Westinghouse company won a similiar suit in a Western circuit, and a similiar suit is now pending in Pennsylvania.

The decision has no bearing whatever on the transmission-of-power invention, the greatest of all Tesla's inventions and one of the greatest of any age, all claims against which have been decided in Tesla's favor.

Stanley Instruments Held not to Infringe Tesla Split-phase Patents.

Judge Colt of the United States Circuit Court, District of Massachusetts, has handed down a decision in the suit brought by the Westinghouse Electric and Manufacturing Company against the Stanley Instrument Company of Great Barrington, Mass., for alleged infringements of certain Tesla patents, holding that the complainant failed to establish the conception by Tesla of the inventions in suit prior to April 22, 1888, the date of the Ferraris publication. The patents in suit are what are commonly known as the Tesla split-phase patents, and they were held to be non-infringed by the Circuit Court of Appeals in a similar suit by the Westinghouse company against the Catskill Illuminating and Power Company, as stated in the Western Electrician of March 7th. The same evidence was produced by the complainant in both cases, so that Judge Colt considers an opinion unnecessary, as it would be only a repetition of the decision of the Appellate Court. The bill is accordingly dismissed with costs.

Tesla Double-circuit Selective Space-telegraph System.

Nikola Tesla has found that, notwithstanding all constructive advantages and experimental resources, the method of selective signaling in space telegraphy, as commonly practiced, is in many cases inadequate. Thus, while he has succeeded in so operating selectively under certain favorable conditions more than 100 receivers, in most cases it is practicable to work successfully but a few, the number rapidly diminishing as, either owing to great distance or other causes, the energy available in the tuned circuits becomes smaller and the receivers necessarily more delicate. Evidently, a circuit however well constructed and adjusted to respond exclusively to vibrations of one period is apt to be affected by higher harmonics, and still more so by lower ones. When the oscillations are of a very high frequency, the number of the effective harmonics may be large and the receiver consequently easily disturbed by extraneous influences to such an extent that when very short waves, such as those produced by Hertzian spark apparatus, are used little advantage in this respect is to be derived from tuning the circuits.

"It being an imperative requirement in most practical applications of such systems of signaling or intelligence transmission," says Mr. Tesla, "that the signals or messages should be exclusive or private, it is highly desirable to do away with the above limitations, especially in view of the fact which I have observed, that the influence of powerful electrical disturbances upon sensitive receivers extends even

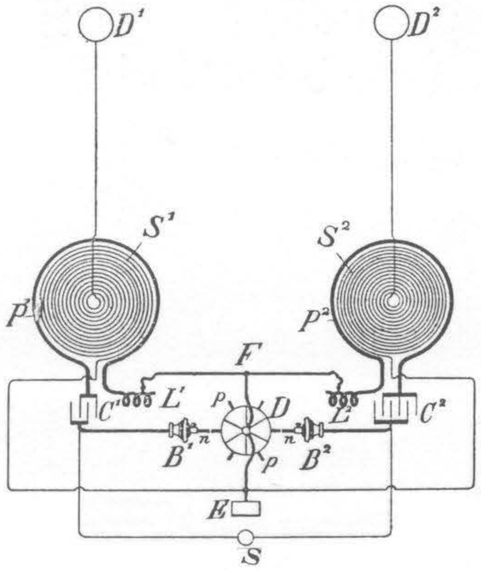

FIG. 1. TESLA DOUBLE-CIRCUIT SELECTIVE SPACE-TELEGRAPH SYSTEM.—SENDING STATION.

on land to distances of many hundreds of miles, and consequently, in accordance with theory, still farther on sea." To overcome these drawbacks and to enable a great number of transmitting and receiving stations to be operated selectively and exclusively and without any danger of the signals or messages being disturbed, intercepted, or interfered with in any way is the object of an invention recently patented by Mr. Tesla.

Broadly stated, this invention consists in generating two or more kinds or classes of disturbances or impulses of distinctive character with respect to their effect upon a receiving circuit and operating thereby a distant receiver which comprises two or more circuits, each of which is tuned to respond exclusively to the disturbances or impulses of one kind or class and so arranged that the operation of the receiver is dependent upon their conjoint or resultant action.

By employing only two kinds of disturbances or series of impulses instead of one, as has heretofore been done, to operate a receiver of this kind, he has found that safety against the disturbing influences of other sources is increased to such an extent that he believes this number to be amply sufficient in most cases for rendering the exchange of signals or messages reliable and exclusive; but in exceptional instances a greater number may be used and a degree of safety against mutual and extraneous interference attained, such as is comparable to that afforded by a combination lock. The liability of a receiver being affected by disturbances emanating from other sources, as well as that of the signals or messages being received by instruments for which they are not intended, may, however, be reduced not only by an increased number of the co-operative disturbances or series of impulses, but also by judicious choice of the same and order in which they are made to act upon the receiver.

Figs. 1 and 2 represent diagrammatically an apparatus and circuit connections employed at the sending and receiving stations, respectively, for the practice of Mr. Tesla's invention.

In Fig. 1, (S') (S²) are two spirally wound coils or conductors connected with their inner ends, to preferably elevated terminals (D') and (D²), respectively, and with their outer ends to an earth plate (E). These two coils, conductors, or systems, (D') (S') (E) and (D²) (S²) (E) have different and suitably chosen periods of vibration, and, as pointed out in other patents relating to his system of energy and intelligence transmission, their lengths should be such that the points of maximum pressure developed therein coincide with the elevated terminals (D') (D²). The two systems may have electrical oscillations impressed upon them in any desired manner conveniently by energizing them through primaries (P') and (P²), placed in proximity to them. Adjustable inductances (L') and (L²) are preferably included in the primary circuits chiefly for the purpose of regulating the rates of the primary oscillations. In the drawings these primaries (P') and (P²) surround the coils (S') (S²), and are joined in series through the inductances (L') (L²), conductor (F), condensers (C') and (C²), brush-holders (B') and (B²), and a toothed disk (D), which is connected to the conductor (F), and, if desired, also to the ground-plate (E), as shown, two independent primary circuits being thus formed.

The condensers (C') and (C²) are of such capacity and the inductances (L') (L²) are so adjusted that each primary is in close resonance with its secondary system, as explained in other Tesla patents. The brush-holders (B') and (B²) are capable independently of angular and, if necessary, also of lateral adjustment, so that any desired order of succession or any difference of time interval between the discharges occurring in the two primary circuits may be obtained. The condensers being energized from a suitable source (S), preferably of high potential, and the disk (D) being rotated, its projections or teeth (p p) coming at periodically recurring intervals in very close proximity to or, as the case may be, in contact with conducting rods or brushes (n n), cause the condensers to be discharged in rapid succession through their respective circuits. In this manner the two secondary systems (D') (S') (E) and (D²) (S²) (E) are set in vibration and oscillate freely, each at its proper rate for a certain period of time at every discharge. The two vibrations are impressed upon the ground through

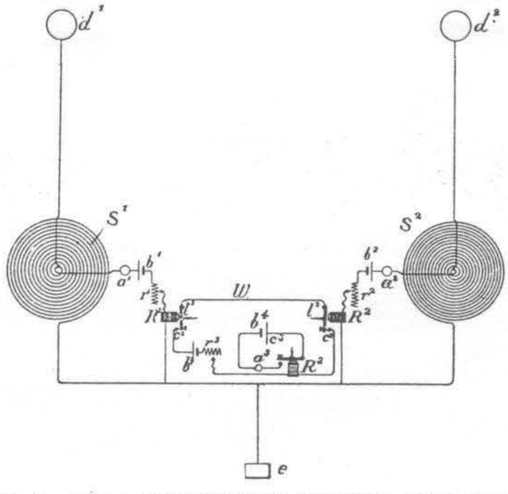

FIG. 2. TESLA DOUBLE-CIRCUIT SELECTIVE SPACE-TELEGRAPH SYSTEM.—RECEIVING STATION.

the plate (E) and spread to a distance reaching the receiving station, which has two similar circuits or systems (e) (s') (d') and (e) (s²) (d²), arranged and connected in the same manner and tuned to the systems at the sending station, so that each responds exclusively to one of the two vibrations produced by the transmitting apparatus.

The same rules of adjustment are observed with respect to the receiving circuits, care being furthermore taken that the tuning is effected when all the apparatus is connected to the circuits and placed in position, as any change may more or less modify the vibration. Each of the receiving coils (s') and (s²) is shunted by a local circuit containing, respectively, sensitive devices (a') (a²), batteries (b') (b²), adjustable resistances (r') (r²), and sensitive relays (R') (R²), all joined in series, as shown. The relays (R') (R²) have armatures (l') (l²), which are connected by a wire (w), and when attracted establish electrical contacts at (c') and (c²), thus closing a circuit containing a battery (b³) and adjustable resistance (r³) and a relay (R³). From the above description it will be readily seen that the

relay (R^3) will be operated only when both contacts (c') and (c^2) are closed.

The apparatus at the sending station may be controlled in any suitable manner—as, for instance, by momentarily closing the circuit of the source (S), two different electrical vibrations being emitted simultaneously or in rapid succession, as may be desired, at each closure of the circuit. The two receiving circuits at the distant station, each tuned to respond to the vibrations produced by one of the elements of the transmitter, affect the sensitive devices (a') and (a^2) and cause the relays (R') and (R^2) to be operated and contacts (c') and (c^2) to be closed, thus actuating the receiver or relay (R^3), which in turn establishes a contact (c^3) and brings into action a device (a^3), by means of a battery (d^4), included in a local circuit, as shown. But evidently if through any extraneous disturbance only one of the circuits at the receiving station is affected the relay (R^3) will fail to respond. In this way a communication may be carried on with greatly increased safety against interference, and privacy of the messages may be secured.

The receiving station shown in Fig. 2 is supposed to be one requiring no return message; but if the use of the system is such that this is necessary, then the two stations will be similarly equipped, and any well-known means may be resorted to for enabling the apparatus at each station to be used in turn as transmitter and receiver. In like manner the operation of a receiver, as (R^3), may be made dependent, instead of upon two, upon more than two such transmitting systems or circuits, and thus any desired degree of exclusiveness or privacy and safety against extraneous disturbances may be attained. The apparatus, as illustrated in Figs. 1 and 2, permits, however, special results to be secured by the adjustment of the order of succession of the discharges of the primary circuits (P') and (P^2), or of the time intervals between such discharges.

"Whatever the nature of the specific devices employed," says Mr. Tesla, "it will be seen that the fundamental idea in my invention is the operation of a receiver by the conjoint or resultant effect of two or more circuits, each attuned to respond exclusively to waves, impulses, or vibrations of a certain kind or class, produced either simultaneously or successively, by a suitable transmitter."

April 1903

THE JOURNAL OF ELECTRICITY, POWER AND GAS. [Vol. XIII—No. 4

THE TESLA SPLIT-PHASE PATENTS.

JUDGE COLT, of the United States Circuit, District of Massachusetts, on March 11th, handed down a decision covering the Tesla split-phase patents, the parties to the suit being the Westinghouse Electric and Manufacturing Company and the Stanley Instrument Company. The opinion, which is very brief, refers to the recent decision of Judge Townsend in a suit on appeal in which the same patents were involved.

The opinion states that upon careful consideration of the evidence, the court has reached the conclusion that the complainant has failed to establish, by sufficient proofs, the conception by Tesla of the inventions in suit prior to April 22, 1888, the date of the Ferraris publication. In a complainant's supplemental brief no reasons were found stated or authorities cited which should lead the court to any different conclusion. Since the hearing in case at bar, the Circuit Court of Appeals for the Second Circuit, in a suit invoking the same patents brought by the complainant against the Catskill Illuminating and Power Company, upon the same evidence which was before the present court, has held that the proofs were insufficient to establish invention by Tesla prior to April 22, 1888. Judge Colt considers that this decision, which was passed down February 26, 1903, renders unnecessary an extended opinion by him, since it would be only repetition of the views so clearly expressed by Judge Townsend in the opinion of the court in the Catskill case. A decree is to be entered dismissing the bill, with costs.

Loaded Lines in Telephonic Transmission.—CAMPBELL.—A mathematical investigation of the effect of inserting self-induction coils on long telephone lines as in Pupin's system, and an account of some experiments. He worked with a cable circuit 46 miles in length, partly artificial, containing 100 equally-spaced inductance coils. The initial loss due to the loading was found to be equivalent to the introduction of 9 miles of standard cable, but on account of the greatly reduced attenuation, the loaded line is better than the unloaded line for all distances greater than 15 miles. In the author's arrangement, the distance over which transmission could be obtained was nearly trebled by the loading, and the quality was improved in addi-

tion. At the transmitting end a person talked in a steady, monotonous manner, and at the receiving end a person could switch instantly from the loaded line to the artificial cable standard, to compare the clearness of transmission over the two. The comparison gave the equivalents of the two circuits for commercial service. The author admits that much further experimental work remains to be done.—*Phil. WIRELESS TELEGRAPHY IN THE UNITED STATES.

By E. GUARINI.

The first experiments in wireless telegraphy, and the first patents taken out in connection with this branch of telegraphy in the United States, date from long ago. Without going back to the attempts of Morse in 1842, we must begin as far back as 1891. In that year, in his patent No. 465,971, dated December 29th, taken out for his system of transmission of electric signals, Thomas Alva Edison expressed as follows his first claim:—"A method of transmitting signals between stations separated from one another, consisting of an elevated condensing surface at each station, of a transmitter connected with one of these condensing surfaces in order to modify its electric tension according to the signal to be transmitted, and thus varying in a corresponding manner the tension of the other condensing surface, and of a receiver connected with the other condensing surface in substance as described."

Few people have a clear or adequate idea of the importance of this patent of Edison's in the history of wireless telegraphy. The greater number of the component parts of the present systems of wireless telegraphy are found in it; the antennæ, the coil, the connections to earth. The receiver of the future will probably be Edison's, *i.e.*, a receiver in which the energy of the wave works directly the apparatus that operates the signals.

A complete Edison station was constituted as follows (fig. 1):—A source of current, either variable in itself or

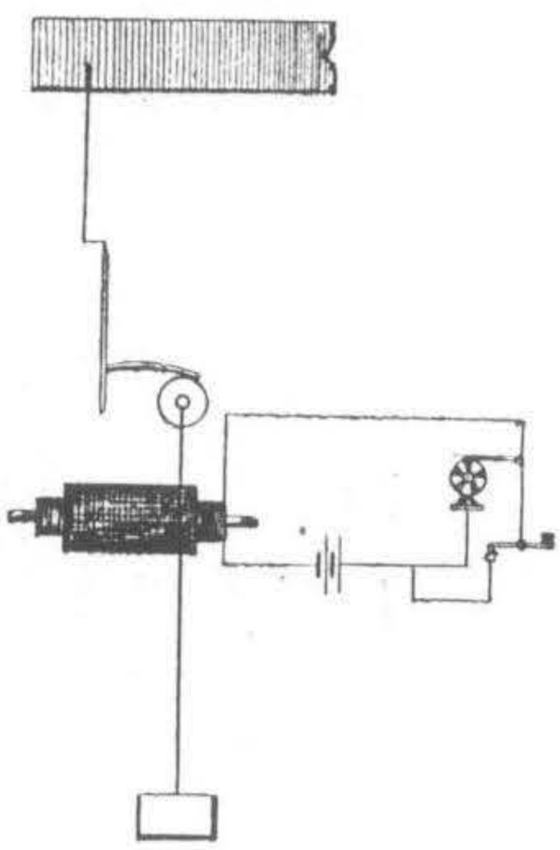

Fig. 1.

rendered so by an interrupter, fed the primary of an induction coil, the secondary of which was, at one end, connected to earth; and at the other through a telephone by a vertical wire to a capacity, *e.g.*, a plate, placed at a certain height.

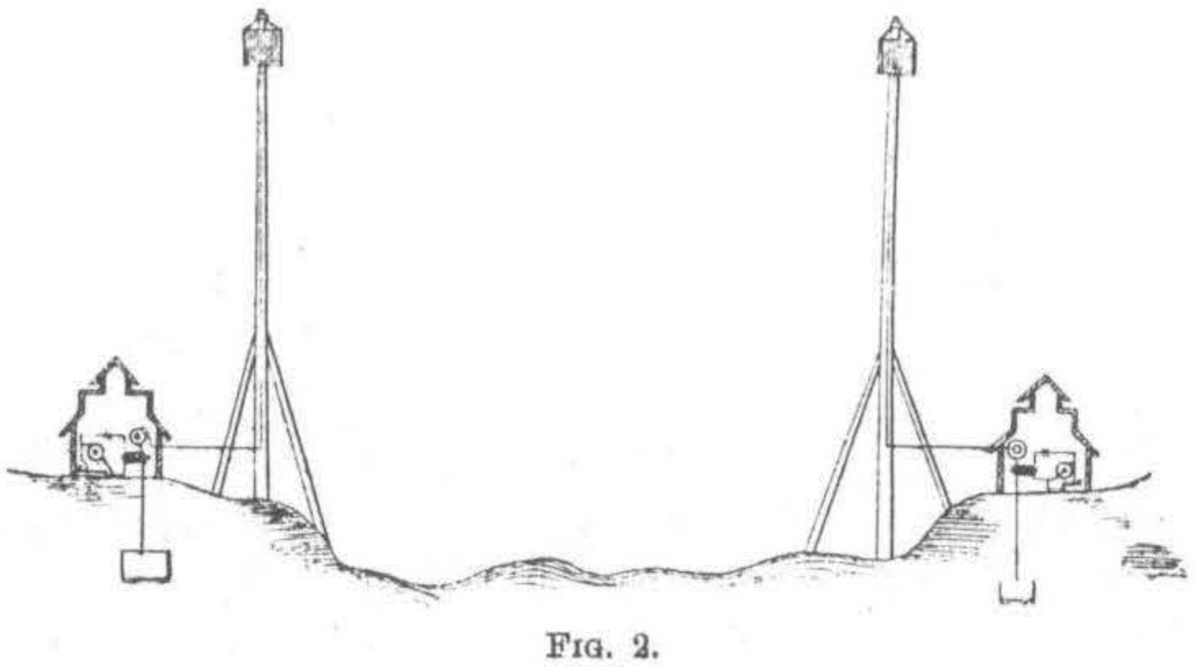

Fig. 2.

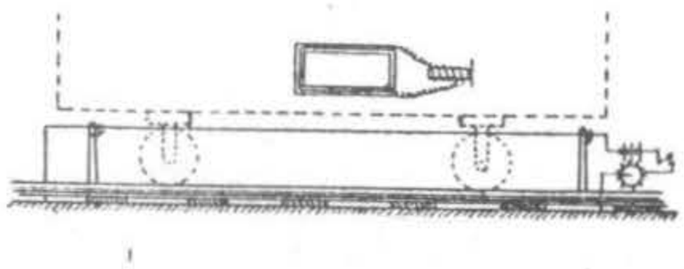
Communication was established between two stations by providing each of them with a similar apparatus (fig. 2). On working the coil the high pressure current of the secondary charged the antenna and the capacity. An induced current

was produced in the capacity and in the antenna of the other station. This current proceeded towards earth through the winding of the telephone. A sound was heard in the telephone, and its duration was in proportion to that of the primary current.



The writer may remark in passing that it was with the aid of the Edison transmitter, and by the substitution of a coherer for the telephone in the receiver, that he was able to effect the overland experiments over a distance of 44 km. between Brussels, Mechlin and Antwerp (Electrical Review, May 24th, June 7th and 28th, and July 12th, 1901), and by means of which he is able to dispense with the Hertzian waves, which are generally thought indispensable, in realising long-distance wireless telegraphy. This is in no way surprising: the current which an antenna on open circuit can send out is the product of the frequency and the capacity. Thus two methods of radiating great energy present themselves:—(1) To use a high frequency (Hertzian waves) and antennæ of small capacity. This is the method employed by Marconi, Braun, Slaby, &c. (2) To employ a current of low frequency and antennæ of great capacity. This is the method used by Edison and by the writer.

In concluding these remarks upon the Edison system, we will here quote a passage from his patent, which will remain one of the most noteworthy pages in the still early history of wireless telegraphy:—"I have discovered," says Edison, "that if we get an elevation sufficient to clear the curvature of the earth, and to reduce to a minimum the absorption of the earth, electric telegraphy, or the interchange of signals between far distant points, can be worked by induction without the use of wires connecting these points. This discovery is specially applicable to telegraphy across masses of water, so as to avoid the use of submarine cables, or to communication between vessels at sea or between vessels at sea and stations on land; but it is also applicable to electric communication between distant points on land, although on land (except in the case of open prairies) there is always the necessity of increasing the elevation in order to reduce to a minimum the absorbing effect of houses, trees, and elevations of the ground itself. At sea, with an elevation of 100 ft., I can send electric communications to a great distance, and as this height can be attained by using the masts of ships, signals can be transmitted and received between vessels separated by a considerable distance, and if these signals are repeated to other vessels, communication can be established for any distance, even across the largest seas and oceans. Collisions during fogs can be prevented by this system of signals, which might also be used to warn a vessel approaching a dangerous coast during foggy weather. For communications between points on land, poles of great height may be used, or captive balloons."

Edison, as we see, proposed captive balloons, antennæ, repeaters—in fact, all that is now being used, and all that is at present likely to be used, at any rate on land.

After Edison's apparatus, those designed by Mr. Phelps, with a view to effecting communication between trains in

Fig. 3.

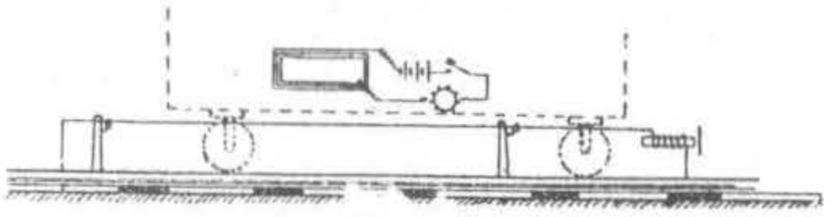


Fig. 4.

motion, are worthy of attention, though they are not strictly wireless (figs. 3 and 4). The system comprises:—

1. Between the rails a line, the extremities of which are connected to earth.

2. A rectangular coil placed vertically on the train, as near as possible to the line.

The transmitting system comprises a variable source of current, *e.g.*, a toothed wheel interrupting the current of a battery; the receiving system, a simple telephone. Fig. 3 shows the arrangement required for sending signals to the train; fig. 4, that which is required at a station for the reception of signals sent by a train.

In order to allow of communications in both directions, each station consists of a transmitter and a receiver, placed in circuit in succession.

An application having the same object was designed by Gilliland with a modification of the Edison system. In the Edison-Gilliland system, as applied to railways, a line goes along the track; the metal roofing of the carriage constitutes the capacity of the Edison system; the wheels form the connection to earth. In the line, as on the train, the Morse key serves to switch on the antenna.

Another most interesting patent was taken out in 1897; this time by Mr. Nicola Tesla, who has become famous through his Martian communications and his towers, which in 1899 were constructed for wireless telegraphy. He took out the patent in question for "improvements in the system for the transmission of electrical energy, and in the apparatus used for this transmission." The title is most modest, but when we penetrate into the details we soon perceive that we have before us a Pindaric flight of the fertile imagination of the child of Montenegro.

In principle the Tesla method consists in establishing a circuit in which the rarefied air of the upper strata of the atmosphere serves as the outgoing and the earth as the return conductor.

As in the Edison system, the transmitter consists of an induction coil, but an induction coil of special construction, the high pressure circuit of which is connected at one end to earth and at the other to a disc supported by a balloon in the rarefied air of the upper strata of the atmosphere. The arrangements made for the reception are similar to those used for the transmission. The fine wire winding of the transformer is connected at one extremity to earth and at the other to the aerial disc. The thick wire circuit of the transformer comprises lamps, motors, &c., which it is designed to feed.

Without doubt electricity owes some important discoveries to Tesla. But in this case we fear that his so-called invention, or discovery, will remain a dead letter and never be carried out in a practical way.

Tesla compares his system to a Geissler tube fed by the secondary of an induction coil, and draws from this comparison conclusions too long to reproduce here. But is the comparison justified? Can the Tesla system really be compared to the Geissler tube? That is the question. Admitting that a sufficiently high pressure can be produced to overcome the resistance of the earth and of the rarefied air, why should the current go towards the Tesla receiver, and not in all directions? Would not the conduction of the air and the earth constitute a serious difficulty? We can limit the area of *radiation*, but how can we limit the *conduction* of the earth and the atmosphere to certain sectors? Moreover, if the whole of the surrounding earth and atmosphere be involved, has Mr. Tesla thought what a small quantity of energy would arrive at his receiver, if, indeed, any arrived?

Mr. Tesla, however, has not given up his idea, and does not own himself beaten. Moreover, the New York *Electrical World and Engineer* recently published an engraving and a short description of a tower constructed by Tesla at Wardencliff with a view to experiments in wireless telegraphy, and in the transmission of energy without conductors to Europe and Australia, where corresponding stations are to be established. *Qui vivra verra!* In the meantime, let us glance at some other systems.

(*To be continued.*)

THE ROYAL SOCIETY SOIRÉE.

THIS year, for the first time within our recollection, the annual soirée of the Royal Society was held on Friday night instead of Wednesday night. The change, no doubt, is due to the altered rules under which Parliament works. Formerly Wednesday night was an off evening in the House, and members were at liberty to attend the conversazione of the Royal Society; under the present rules they are all occupied on Wednesday, and Friday is the only evening which they have at leisure. The meeting last Friday, the 15th inst., was a highly successful one, and was attended by the Prince of Wales and by a very large gathering of men of science and others. The collection of exhibits for the instruction and amusement of the visitors was rather smaller than the average, and excepting Sir William Crookes's display of the emanations of radium, it can scarcely be said that there was much that was either new or important. There was, however, a good level of excellence all round, and the visitors found plenty to attract them.

The Rev. F. J. Jervis-Smith, F.R.S., showed his high-pressure spark-gap for Tesla inductors. The spark-gap consists of two brass balls, platinum faced, fixed at an adjustable distance in a glass sphere, which can be charged with compressed air. The gap and the inner coatings of two Leyden jars were joined in the secondary circuit of a Tesla inductor, the outer coatings to the primary. The brush discharge in air is changed into a torrent of thick sparks when the air pressure in the sphere is raised to 40 lb. per square inch, and a glass plate nearly $\frac{1}{2}$ in. in thickness, placed between two point terminals in an oil-trough, is at once perforated. Yet that discharge is physiologically harmless, and only pricks the finger a little when approached to one of the terminals. Another peculiarity is that if a spark strikes a vacuum glass tube without electrodes, a greenish glow appears on the inner coating opposite—not on the coating nearest to the point struck—and at any point earthed outside through the hand in which the tube is held; this glow emits Röntgen rays, and gives good skiagraphs. The sparks also produce Hertzian waves, a property which has been utilised in wireless telegraphy. For this reason Mr. Jervis-Smith has probably resumed these interesting experiments, which date back to 1892 and 1896.

Mr. Tesla and His Oscillator.

The New York Sun, which is supposed to have excellent sources of information in matters relating to the work of Nikola Tesla, published this short but interesting editorial in its issue of May 31st:

"It is now a little more than two years since the Sun gave to the world Mr. Tesla's announcement that, some time within the eight months following, he would send a wireless telegram across the Atlantic Ocean.

"With the failure of that prediction the public is familiar, although not with the immediate cause. As we understand it, progress toward fulfillment revealed possibilities so much greater that it was determined to aim at a higher mark, and we are now authorized to say, in Mr. Tesla's behalf, that some time within the present year he will send wireless telegrams to the other side of the world. The Tesla oscillator is to deliver to the earth the shock that will be felt and recorded on its uttermost confines.

"As before, we have to wait and see, doubtful because of the miraculous character of the task, but hopeful on the strength of the wonders that science has already done."

Tesla Patent Litigation.—An important decision was lately given by the United States Circuit Court of Massachusetts in the case of the Westinghouse Electric and Manufacturing Company against the Stanley Instrument Company for alleged infringement of certain patents of Nikola Tesla. A similar suit was brought against the Catskill Illuminating and Power Company, and resulted in the Circuit Court of Appeals giving judgment, as in the first-mentioned case, in favour of the defendants. The point involved was as to the priority of invention. The claims of the first patent which came up for consideration cover a certain method, and of the second certain means of operating electrical motors by means of alternating currents from a single original source. This system is known as the "split-phase" system. Nikola Tesla was the inventor of what is known as the polyphase system of transmission of power, and had covered by his earlier patents the said system when operated by means of currents of varying phase from independent lines or circuits. By the methods and means therein described Tesla dispensed with one of the line circuits, and was able to run the motor by means of alternating currents from a single original source. This was accomplished by means which so retarded the phases of the current in certain circuits, or so varied the relative resistance of the motor circuits, as to maintain the necessary difference of phase in the circuits. Such utilisation of a single original source by thus splitting a single current into two currents was an improvement of great practical value. But on April 22, 1888, there had been published at Milan, in an Italian journal, a report of a lecture by Prof. Galileo Ferraris, in which the system covered by the patents in suit was fully described. This printed publication is such a disclosure of the subject matter of the patents that if prior thereto it would constitute an anticipation. After reviewing the evidence the court found that the claims of Telsa had been anticipated, and that there was therefore no infringement of his patents

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. FOURNIER D'ALBE.]

Energy of Transmission in Wireless Telegraphy.—The energy available for wireless telegraphy with a Tesla transformer depends upon the capacities which can be introduced into the exciting circuit and upon their discharge potential, and hence the antennæ should have a large surface so as to facilitate their being tuned to an exciting circuit containing high capacities. But when induction coils are used, a certain value of these capacities cannot be exceeded without interfering with the proper working of the coils, and the antenna can, therefore, not go beyond certain dimensions. On the other hand, since the discharge potential is nearly inversely as the capacity, the available energy is sensibly constant, and it is usual to tune the antenna to two or three turns only of the Tesla secondary. Marconi has solved the difficulty by first devoting all the available energy to produce oscillations of any period in a primary circuit of the highest possible capacity. These oscillations are then brought to a high potential by means of a first Tesla coil, which charges another capacity, so that its period of discharge can be adjusted to the antenna by means of a second Tesla coil. G. Ferrié proposes an alternative scheme. He divides all the capacities which the transformer can charge into two or more groups placed in different oscillating circuits, but mounted on the same oscillator. All these circuits, adjusted to equal periods, act upon the antenna through as many Tesla coils whose secondaries are mounted in series or in parallel on the antenna. Adjustment is made by trial with a thermal ammeter, which must show the maximum reading.

[G. FERRIÉ, *Comptes Rendus*, June 2, 1903.]

The New York Sun July 17, 1903

TESLA'S FLASHES STARTLING.

But He Won't Tell What He Is Trying For at Wardenclifte.

WARDENCLIFFE, L. I., July 16.—Natives hereabouts are intensely interested in the nightly electrical display shown from the tall tower and poles in the grounds where Nicola Tesla is conducting his experiments in wireless telegraphy and telephony. All sorts of lightning were flashed from the tall tower and poles last night. For a time the air was filled with blinding streaks of electricity which seemed to shoot off into the darkness on some mysterious errand. The display was continued until after midnight.

This morning workmen about the plant declined to say anything. It is understood that Tesla has a well more than 200 feet deep driven beneath the tower and that the electrical waves are sent both underground and through the air.

Mr. Tesla said last evening that the evidences of experiments which have been seen by the people of Wardenclifte, near which his laboratory is located, have been going on for some time there, but that he had no announcement to make at this time as to their character or the success that had been achieved.

"It is true," said Mr. Tesla, "that some of them have had to do with wireless telegraphy and that in addition to the tower and poles there is a hole dug in the ground. This is 150 feet deep and is used in these experiments. The people about there, had they been awake instead of asleep, at other times would have seen even stranger things. Some day, but not at this time, I shall make an annnouncement of something that I never once dreamed of."

The New York Tribune July 19, 1903

STRANGE LIGHT AT TESLA'S TOWER.

Manager, However, Refuses to Explain Its Significance—Inventor's Reserve.

From the top of Mr. Tesla's lattice work tower, on the north shore of Long Island, there was a vivid display of light several nights last week. This phenomenon provoked the curiosity of the few people who live near by, but the proprietor of the Wardencliffe plant declined to explain the spectacle when inquiries were addressed to him.

For several years Mr. Tesla has been talking about wireless telegraphy and the transmission of electricity for commercial purposes through the upper air. So numerous were the postponements of any actual consummation that the public began to fear that nothing would ever come of the prophecies attributed to this inventor. The outlook was more encouraging when he bought land at Wardencliffe two years ago, and began putting up a tower there and building workshops and a laboratory. The latter having been completed, they have taken the place of those long used by him in Houston-st. The tower was 150 or 200 feet high, and had a well underneath.

In a conversation reported by The Tribune on November 27, 1901, Mr. Tesla said that he would probably install an engine of 100 horsepower to drive his dynamo. In connection with this he intended to use that combination of the condenser and induction coil with which he has for several years been able to produce high pressures. This resembles the outfit at Marconi's Glace Bay and Cape Cod stations. In some experiments in his laboratory and in public lectures Mr. Tesla has often produced a brilliant light at one end of a wire, and has taken photographs therewith.

From what Mr. Tesla has himself said on several occasions it might have been inferred that he had abandoned wireless telegraphy altogether, and was planning only a transient power. So long as he continues to maintain his usual mysterious reserve the public can adopt any one of half a dozen explanations of his conduct. Though sensitive to criticism, he sometimes appears to be oblivious to some of the uncomplimentary interpretations which are put upon his delays.

Action of Tesla Coil on Radiometer.

THE following phenomena, observed while experimenting with a small Tesla coil, will, I believe, interest some of your readers. Not having access to the necessary literature, I am not in a position to find out whether they are new or already known.

The knobs of the Tesla coil were placed in contact with, or just close to, the bulb of a Crookes's radiometer, and the coil set at work. When the brush discharge fell upon the bulb, the blackened surfaces of the vanes first retreated, as they do under the influence of radiant heat, but soon the direction of rotation changed, and the blackened surfaces moved forward, the motion continuing as long as the brush discharge fell upon the bulb.

At the same time, inside the bulb, were seen diverging from the glass sides close to the knobs two cones of pale blue light, which, falling on the opposite sides of the bulb, caused a yellowish-green fluorescence. On the fluorescent parts the shadows of the rotating cones were clearly visible, the shadow on one side being always more intense than on the other side. When the direction of the current in the charging Ruhmkorff was reversed, the shadows exchanged places, but no change in the direction of rotation of the vanes was noticed.

On examining the fluorescent parts with a screen of potassium platinocyanide, the same effects were noticed as with the X-ray tubes.

Similar effects were obtained on repeating the experiments with two incandescent lamps in the laboratory. The larger of these, an old Swan lamp, fluoresced green, and the smaller new one, supplied with the Tesla coil by the manufacturer, fluoresced blue. But in both cases, though somewhat feeble, the same X-ray effects were observed.

To study further the cause of the motion of the vanes of the radiometer, the experiment was repeated with a Crookes's tube containing a freely suspended wheel with transparent mica waves. In this case it was found possible to alter the direction of rotation of the wheel by adjusting the positions of the knobs of the Tesla coil relatively to the sides of the tube and the wheel inside it.

P. L. NARASU.

Christian College, Madras, June 18.

Tesla's Doings.

According to the newspapers, strange things are happening at Wardencliffe, L. I., where Tesla has his laboratory.

Ever since Mr. Tesla retired from the public gaze and hid himself in Long Island, he has been credited with performing strange feats. These rumors are at last confirmed. For some time, residents about the laboratory have been startled by vivid flashes of light emanating from a tall tower erected by the inventor. Just what this tall tower, and the gleams and flashes which come and go, may mean, no one knows; but it is to be inferred that Mr. Tesla is bent upon improving the present methods of telegraphing by the Hertzian waves.

The New York Tribune August 3, 1903

TESLA'S TUNING PLAN.

IT ASSURES SECRECY.

An Advance in Wireless Telegraphy —Meddling Impossible.

Any one who has ever tried to persuade Mr. Tesla to talk for publication about his experiments and projects knows how firm and courteous are his refusals. Nevertheless, one source of information about his inventions is open to the public. His patents are matters of record. Any one may obtain copies by proceeding in the right manner, though familiarity with legal phraseology and electricity is necessary fully to understand them. Two patents, almost identical in tenor, were recently issued to Mr. Tesla. The invention which they cover seems to constitute a distinct improvement in wireless telegraphy, and its character and purpose are perfectly intelligible.

Almost from the first it has been apparent that that system of communication would have a limited application unless secrecy could be insured. Hence, several of the most conspicuous workers in this field have been studying how to attain such a result. While their methods differ in detail, they all agree that the problem is to be solved by "tuning." By that phrase electricians mean a regulation or adjustment of the transmitter which makes it send out waves of a certain frequency—say 500,000 a second—and a treatment of the receiving apparatus which renders the latter more susceptible to that number than to any other. It has been assumed, rashly perhaps, that unless a piratically disposed outsider either knew what frequency was being used, or hit upon it by accident, he could not adjust his instruments so that he could steal a message where "tuning" had been employed. Of course, where no attempt was made to insure such agreement, wireless communications would not be private. In some kinds of service, indeed—as between steamships meeting at sea—no harm would result from overhearing.

In his patent specification Mr. Tesla points out a difficulty which is experienced in the operation just described, and which he has sought to evade. A phenomenon is observed in the generation of electric waves which parallels one in music. If a given tone is produced by a violin string, several others, less audible, will also be emitted. If that tone be the one which is caused by one hundred vibrations a second, the additional but fainter sounds will be those resulting from 200, 300 and other frequencies. Such extra tones, or "harmonics," represent exact multiples of the number of vibrations requisite to the lowest, or fundamental, one, and there are usually six of them. When a Hertz wave generator is put in operation, that, too, produces "harmonics." Besides the one principal frequency which the operator aims to employ, his apparatus will also give out multiples. Mr. Tesla declares that a receiver which has been regulated to respond to one frequency is likely to pick up waves which are given off anywhere from exactly twice to exactly seven times as often. Hence it might receive messages not intended for that station. That system of tuning, therefore, seems less secure than is desirable.

Mr. Tesla's plan certainly appears distinctly superior to this. What he proposes to do is to generate two or more sets of waves at once, and employ them all simultaneously in sending. These might have frequencies proportioned to each other in some such fashion as 13 and 17, or 37 and 43, or 73, 80 and 101. Only a receiver which had been tuned to respond to two or three selected rates of vibration, when all were in use, would be able to pick up a message thus sent. It will be seen at a glance that this scheme differs from the other very much as the many notched Yale key differs from an ordinary latch key. Though Mr. Tesla thinks that only two frequencies would usually be enough, the system admits of considerable multiplicates. Moreover, it may be taken for granted that the mechanism used would admit of a quick alteration of the selected frequencies, like that of the numbers of a combination for a bank safe lock.

Another advantage may result from this invention besides that of secrecy. It may avert mischievous interference. Some years ago, when preparations had been made for reporting the international yacht races off Sandy Hook, the following incident occurred: A press boat went down the Bay, a day or two in advance, to test its apparatus, and began sending messages to land. Persons on another boat, with similar apparatus, sent out signals at the same moment. In consequence, there was a confusing jumble of letters at the receiving station. One message overlapped the other. A few weeks ago, while Dr. Fleming was giving a lecture in London to prove how beautifully the Marconi "tuning" system worked, Nevil Maskelyne sent in "Rats!" and other inappropriate remarks from a point outside, and the speaker's instruments recorded them, much to his embarrassment.

Only last week Dr. Slaby, the author of one of the German systems of wireless telegraphy, openly avowed his belief in the propriety of interfering with the receipt of Marconi messages in England by sending out a continuous stream of signals with a powerful transmitter on the German coast. Finally, it is interesting to speculate for about ten seconds as to what would happen at Cape Cod if, while Marconi was trying to send thither from Poldhu, Mr. Tesla were to start up his generators at Wardencliffe. The South Wellfleet receiving operator's hair would probably turn gray with perplexity in the effort to decipher the communications that actuated his instruments.

Quite aside from the morality of such conduct (which might depend on circumstances not known to the public), it seems to be entirely feasible. Apparently, too, a receiver which has been adjusted to respond to Mr. Tesla's combination would be immune against any amount of outside interference. Time only can tell the full value of his latest patents, but an unprejudiced judge can easily see immense possibilities in the idea.

[29.]—**Tesla Coil.**—You will find full directions for making these in my book "Electrical Instrument Making for Amateurs." I know of no book treating of the experiments that can be made with the Tesla, and, in fact, nearly everything that requires high tension can be performed by its aid.

S. BOTTONE.

[29.]—**Tesla Coil.**—Rather a large order for limited space. Experiments can be found in a few up-to-date electrical handbooks, and in a great many of the illustrated science papers.

ELECTROMETER.

Wire for Small Tesla Coil.

To the Editor of *The Model Engineer*.

Dear Sir,—With reference to my former query *re* rubber-covered wire (Reply No. 9,320) for Tesla coil, mentioned at page 515 of The Model Engineer, dated May 28th, I am pleased to say Mr. Pike (the writer of the article) has written to me direct explaining that the primary is built of No. 22 gutta-percha covered wire, and not as stated in the article, and that this can now be obtained from Whitney's.

Mr. Pike was kind enough to send me sufficient of the wire for the coil I am making, and I had sat down to write and thank him for it, when I discovered that he had not sent his address. May I ask, therefore, that you will be good enough to convey to Mr. Pike, in your next issue, if possible, my thanks for his courtesy in writing and sending me the wire. I have no doubt this will also interest your readers, as Whitney's informed me they had several enquiries regarding the same.—Yours faithfully,

Southsea. W. Hack.

The New York Herald September 12, 1903

VICTORY FOR TESLA IN COURT DECISION

He Is Credited with First Obtaining Idea of Utilizing Split-Phase Currents.

IN USE ON SMALL MOTORS

Opinion Given Is in Suit of the Westinghouse Against the Sangamo Electric Company.

Judge Archibald, of the United States Circuit Court of the Eastern District of Pennsylvania, has given an important decision in favor of the Westinghouse Electric and Manufacturing Company in a suit against the Sangamo Electric Company. The decision declares that Nicola Tesla invented the split-phase alternating currents prior to the discovery of the same thing by an Italian electrician named Farraris.

The ownership of the split-phase patents is regarded by electricians as very important. The most successful small motors now use this current. Nearly all fan motors are run by it.

The decision covers about fifty pages of typewritten matter and shows that from the evidence produced Tesla announced his discovery in the latter part of 1887, while Farraris did not make known the result of his investigations until April 22, 1888.

Counsel for the Westinghouse Company said yesterday that the Tesla patents had been recognized generally up to the present and that probably no infringement suits would follow.

The Tesla effect, so called, is the production of a whirling or rotating magnetic force by means of two alternating currents out of phase with each other.

In his fundamental patents Tesla produced these out of phase currents at the generator and transmitted them over three wires to the motor, where they were used to produce the rotating or "Tesla field."

In the split-phase patents he generated a single phase current and transmitted it as a single phase current, and then at or near the motor derived from it the second or out of phase current, which, in conjunction with the transmitted current, is used for producing the same class of rotating field in the motor.

Farraris' invention was along similar lines.

Important Decision on Tesla Split-Phase Patents.

Judge Archbold, in the United States Circuit Court, Eastern District of Pennsylvania, has just handed down a decision in the suit of the Westinghouse Electric and Manufacturing Company *vs.* H. C. Roberts and the Sangamo Electric Company, which has an important bearing on alternating-current meters and fan motors. The suit was under the so-called Tesla split-phase patents. The defendants' device against which suit was brought was the Sangamo electric meter. The Court, after a careful review of the testimony, decided that the complainant had proved satisfactorily that Tesla's date of invention preceded that of Ferraris's and others, and that the device in question was an infringement.

The importance of these patents is great, as some of the most successful alternating-current meters and motors of small size are tributary to them.

The following is an abstract of Judge Archbold's review of the testimony:

The patents in suit and those on which they are based, or which are kindred to them, have been so fully considered in previous cases which until recently have also been uniformly in their favor, that little is left to be brought forward with regard to them.

The deriyitive patents in suit, numbers 511,559 and 511,560, were first considered in the Dayton fan and motor case, 106 Fed. 724; affirmed in 118 Fed. 562, and a decision rendered in substantial accord with those which had preceded it. One defence there, as here attempted to be made, was that it involved no inventive skill when once the practicable use of alternating currents of different phase was established, to substitute the dephased split current which was a well recognized equivalent; but it was not so held, nor can it be here.

The patents in suit were also before Judge Lacombe in the Westinghouse Electric and Manufacturing Company *vs.* the Catskill Illuminating and Power Company, 110 Fed. 377. In addition to the attack made upon them in other cases, it was further urged that, in a paper read by Professor Ferraris before the Royal Academy of Sciences, of Turin, Italy, March 18, 1888, a portion of which was published on April 22 following, at Milan, in *L'Elettricita,* not only was there a full disclosure of the transmission of electric power by means of alternating currents of different phase, but also the use for the same purpose of a dephased split current derived from a single source, the same as in the patents in suit. Upon a due consideration of the opposing proofs the invention of Tesla was held to be carried back of this publication; but on appeal, the decision was reversed, the evidence brought forward by the complainants not being considered sufficient for that purpose; 121 Fed. 831; a conclusion which was followed by Judge Colt in a case by the same plaintiffs against the Stanley Instrument Company, in the first circuit, not yet in print. This, and the matter of infringement, are the overshadowing questions in the present case.

The Ferraris publication, as we have seen, was April 22, 1888, and the patents in suits were not applied for until December 8 following. To relieve from this apparent priority the invention has, therefore, to be carried back of the earlier date by competent and convincing evidence. That Tesla, early in May, 1888, had a complete grasp of the split-phase idea is established by his application of May 15 for patents, Nos. 511,915 and 555,190, which embody it, the same that were before Judge McPherson in the Scott & Janney case 97 Fed. 582, already alluded to. This is important evidence which can not be contradicted and I, therefore, start with it. Not only is the invention beyond question carried back by it to the date named, which is within twenty-three days of the Ferraris publication, but from the known order of events, a patent not being able to be worked out in a day, ground is thus persuasively laid for an earlier date if there is any fair evidence to warrant it. In the face of it, I hardly see how we can doubt the accuracy of Mr. Page's statement that Tesla disclosed to him the principles of the invention somewhere in the first part of April of that year. His testimony on this point is specific and convincing. In the fall of 1887 and spring of 1888, as he says, he was engaged in developing in the Patent Office a number of Tesla's inventions, and among them the polyphase motors and transformers which were patented May 1, 1888. These were prosecuted to an allowance in the early part of April, the final fees, as shown by the books of the firm of which he was a member, having been forwarded to Washington on April 6. After having secured the allowance of this group and made arrangements for similar applications in a number of foreign countries for patent to issue simultaneously therewith, Tesla gave him the material for application one feature of which was the inducing of one current from another in the operation or construction of a motor, and in this connection disclosed to him his plan for operating his polyphase motors by means of a single split-phase circuit. Startled by this revelation and questioning whether the claims which he had drawn in the pending cases would protect this new improvement he had a long conference with Tesla, getting from him all that he could as to the different ways he proposed to operate this two-wire system. It seems to me convincingly established that prior to April 22 the date of the Ferraris publication, Tesla had disclosed to Mr. Page, his solicitor, the principle of his split-phase adaptation.

But the testimony of Mr. Page is by no means all there is upon this subject. Mr. A. S. Brown formerly connected with the Western Union Telegraph Company, became interested in the summer or fall of 1887 in bringing out the original Tesla motor; and he testifies that once when it was first brought to his notice it occurred to him as a great objection that it required two separate currents; not long after which Tesla showed him how it could be operated on a single main line from the generator.

So far as I have considered only the proofs, about which no question can be raised, and basing my decision solely upon them, I am satisfied that the patents should be sustained.

The question of infringement still remains. At the time suit was brought, the defendant, Roberts, was engaged at Philadelphia in the sale of Gutmann recording wattmeters, as agent for the Sangamo Electric Company, of Springfield, Ill., by whom they were made.

It is contended that a meter is not a motor, and that on this ground of itself no infringement can be charged. No doubt the strict object of a meter of this class is to measure and record the element which passes through or actuates it, gas, water, the electric current, or whatever it may be; but where, as here, it is, in mechanical construction, nothing more than an adopted motor with meter attachments, it can not escape infringement on that plea.

The Tesla motor as an invention, was first in its own peculiar field, and is entitled in consequence to a liberal application of the doctrine of equivalents, and of the substantial equivalency of the defendants' device I am fully convinced. The significant thing in each is the conjoint or resultant action of the two opposite sets of poles, the magnetic influence, whether of attraction or repulsion, waxing and waning, and shifting progressively about the armature, of the existence of which there can be little doubt. It is persuasive of the equivalency of operation which is so contended for, although by no means conclusive of it, in a patent applied for by Tesla May 20, and granted December 3, 1889, this equivalency is assumed without explanation as being within the terms of the invention. Other confirmations of the equivalency of the two arrangements with that of a Tesla motor, as well as with each other, could be drawn from this record, but these must suffice. They establish to my satisfaction the general infringing character of the defendants' meter as is charged.

Finding therefore that the patents in suit are valid and have been infringed, a decree is directed in favor of the complainants in the usual form, with costs.

Tesla Split-Phase Patent Sustained.

Judge Archbold, of the United States Circuit Court for the Eastern District of Pennsylvania, has handed down a decision in a case involving the Gutmann wattmeter, which sustains the fundamental Tesla split-phase patent. The principal defense was a publication by Ferraris in 1888 on the rotary field and of the means for obtaining polyphase from single-phase currents. These disclosures were made in a paper read by Prof. Ferraris before the Royal Academy of Sciences of Turin, Italy, in March, 1888, a portion of which was published on April 22 following, in *L'Elettricita.* The Tesla patents in suit were not applied for until December 8 following, but the court held that the testimony in the case showed conclusively that Tesla had, early in May, 1888, a complete grasp of the split-phase idea; and not only is the invention beyond question carried back by it to that period, but the patent not being able to be worked out in a day, ground is thus laid for an earlier date if there is fair evidence to warrant it. The court holds there is such evidence, testimony showing that Tesla disclosed the principles of his invention at a date prior to April 22 to his patent solicitor, the date being somewhere between the 8th and the 18th of April. This evidence is supported also by the testimony of a former business associate of Mr. Tesla, who states that Tesla spoke to him of the idea in the summer or fall of 1887. The date claimed by Tesla of his discovery was September, 1887.

After reviewing at great length the testimony as to priority between Ferraris and Tesla, and deciding in favor of the latter, the court considered at equal length the question of infringement of the Tesla split-phase patent by the Gutmann meter. Its conclusion is that the construction of the meter is in effect a motor in which the armature is operated upon by two independent interconnecting circuits produced by passing through them a divided and dephased alternating current derived from a single source, this apparently realizing the patents in suit. After further consideration of the principles of the meter in suit, the court decided that the meter infringed the Tesla patent. The finding is that the patents in suit are valid and have been infringed.

An interesting portion of Judge Archbold's opinion is that in which he gives a history to date of the opinions rendered in suits involving the Tesla split-phase patents. Judge Townsend, in reviewing the fundamental patents, discussed the alleged disclosures of Siemens, 1878; Bailey, 1879; Deprez, 1889, 1884, and Bradley, 1887, and the claims advanced for them as anticipations, which he held to be unfounded, and these conclusions were affirmed on appeal. The essence of the invention was declared by Judge Townsend to be "the production of a continuously-rotating or whirling field of magnetic forces for power purposes by generating two or more displaced or differing phases of the alternating current, transmitting such phases with their independence preserved to the motor, and utilizing the displaced phases as such therein."

The same patents came up before Justice Brown and a similar result was reached. The Dumesnil (1884) and the Cabanellas (1885), two French patents, which had not been brought forward before, were particularly relied on as anticipations, but were distinguished from those in suit in a carefully-expressed and convincing opinion. These French patents, however, according to Judge Brown, established that Tesla was not the first to employ alternating currents out of phase with each other for power purposes, so that the expressions in previous cases which attributed this to him would have, as he thought, to be qualified if not recalled. But it was at the same time pointed out that in neither the Dumesnil nor the Cabanellas was there a resultant magnetic force, the distinctive feature of the Tesla invention; each of the others named providing for the independent action of separate alternating currents operating on different ends of the motor armature without any play of the magnetic and electric forces in between. "As it stands, the Cabanellas patent is unintelligible to me, but taking it as it is explained by the defendant's experts and illustrated by the exhibit in evidence (of the correctness of which, however, I have much doubt), there is nothing more at the best than a mechanical combination of the two operative devices like the opposite cranks on the same axis of a locomotive driving wheel. There is no conjoint operation as in a Tesla motor of the two energizing circuits by means of a combined magnetic influence to produce a common result. It is important, however, to observe that while in no sense anticipations, the Dumesnil and Cabanellas serve to limit the invention of Tesla—if not, indeed, so limited in his patents themselves—to a device in which a magnetic resultant of dephased alternating currents exist, the mere use of alternating currents out of phase with each other made otherwise effective being something aside and different."

The derivative patents in suit were first considered in the Dayton Fan & Motor case and affirmed, and a decision rendered in substantial accord with those which had preceded it. One defense there, as in the present suit, attempted to be made, was that it involved no inventive skill when once the practicable use of alternating currents of different phase was established, to substitute the dephased split current which was a well recognized equivalent; but it was not so held, nor could it be in the present case. This question was practically put at rest in this court by the decision of Judge McPherson in a case where two of the earliest Tesla split-phase patents were sustained. But aside from that, and upon an entirely independent consideration of it, Judge Archbold says the same conclusion must be reached.

The patents in suit were also before Judge Lacombe, and in addition to the attack made upon them in other cases, it was further urged that, in the paper read by Prof. Ferraris before the Royal Academy of Sciences, of Turin, Italy, March 18, 1888, a portion of which was published on April 22 following, at Milan, in *L'Elettricita,* a journal devoted to electrical subjects, not only was there a full disclosure of the transmission of electric power by means of alternating currents of different phase, but also the use for the same purpose of a dephased split current derived from a single source, the same as in the patents in suit. Upon a due consideration of the opposing proofs, the invention of Tesla was held to be carried back of this publication; but on appeal the decision was reversed, the evidence brought forward by the complainants not being considered sufficient for that purpose; a conclusion which was followed by Judge Colt in a case by the same plaintiffs against the Stanley Instrument Company, in the First Circuit, not yet in print. This, said Judge Archbold, in concluding his review, and the matter of infringement, are the overshadowing questions in the present case.

Discussing the contention that a meter is not a motor, and that on this ground of itself no infringement can be charged, Judge Archbold said that, as pointed out by Judge Lacombe in the Catskill case, while the Tesla patents contemplate the production of power, they are silent as to the amount of it; and as a meter armature rotates against the action of a permanent magnet and turns a spindle which operates the registering devices, the production of some power is necessarily involved. It is somewhat aside from the question, but still it is a circumstance that Gutmann himself, in accordance with whose patents the meters in question are constructed, recognizes and claims therein that this device may be used for power purposes also. No doubt the strict object of a meter of this class is to measure and record the element which passes through or actuates it, gas, water, the electric current, or whatever it may be; but where, as here, it is, in mechanical construction, nothing more than an adapted motor with meter attachments, it cannot escape infringement on the plea. Judge Archbold holds that there is nothing in conflict with this, when rightly considered, in what is said in an opinion cited relating to a water meter. The attempt there made was to defeat a special safety appliance of a water meter by references drawn from the general motor art, and it was in that connection that it was held that the two were not the same.

Tesla Split-phase Patents Upheld.

Judge Archbald of the United States Circuit Court for the Eastern District of Pennsylvania has just handed down a decision in the suit of the Westinghouse Electric and Manufacturing Company against H. C. Roberts and the Sangamo Electric Company, which may have an important bearing upon alternating-current meters and fan motors. The suit was under the so-called Tesla split-phase patents. The defendants' device against which suit was brought was a meter formerly made by the Sangamo Electric Company, but the manufacture of which was discontinued about two years ago. The court, after a careful review of the testimony, decided that the complainant had satisfactorily proved that Tesla's date of invention preceded that of Farraris' and others, and that the device in question was an infringement. Evidence was adduced by the Westinghouse Electric and Manufacturing Company showing that Tesla's date of invention was several months prior to the Farraris' publication.

On the part of the Westinghouse company it is declared that "the importance of these patents can scarcely be over-estimated as the most successful alternating-current meters and motors of small size are tributary to them."

For the defendants an appeal will be taken from Judge Archbald's decision to the United States Circuit Court of Appeals for the Third Circuit.

The New York Herald October 9, 1903

MR. TESLA PRAISES PROFESSOR LANGLEY

To the Editor of the Herald:—

I cannot refrain from protesting against the most ungenerous comments in this morning's papers on Professor Langley's efforts. Professor Manly's tests, in view of the great difficulties attending them, should have received more appreciation.

The atmosphere is a capricious medium, and as regards air navigation we are still in a barbarous state of ignorance. Professor Langley undertook many years ago task which has baffled human ingenuity and skill for centuries. He had nothing to go by—not even a theory, let alone practical data.

After long and patient labor, requiring the exercise of the rarest faculties, he finally perceived a great truth, which he announced—the secret of the bird's sailing flight. He recognized that a machine heavier than air could be made to fly provided its mechanism be controlled intelligently and that advantage be taken of the energy of the air currents. Had he accomplished nothing else, this would be enough.

But Professor Langley did not stop at this. He concentrated his efforts toward embodying these principles in a mechanical model. Years were naturally consumed in these endeavors. Experiments are expensive. We are told that he has expended $50,000 in these trials. This is what the public is made to believe.

But those who have had experience know that he not only has spent this sum, but has in all probability exhausted all his own resources.

The reflections made in the papers regarding the expenditure of this paltry sum contributed by the government are not only not justified, but ridiculous in the extreme.

Professor Langley has grasped more thoroughly the problam of aerial navigation than any other man on this globe. There are many skilled mechanics who are lacking in scientific knowledge, there are many scientific men who do not possess sufficient mechanical skill; Professor Langley has both.

His success does not depend on chance. Such a man should be provided with the necessary means to complete his work immediately. Great honor attaches to this achievement, also great practical utility, which this country can ill afford to lose.

New York, Oct. 8, 1903. N. TESLA.

The Colorado Springs Gazette October 30, 1903

TESLA PLANNING TO COME HERE

WATER COMMISSIONER RECEIVES INFORMATION THAT SCIENTIST WILL SOON ARRIVE IN COLORADO SPRINGS.

Water Commissioner E. W. Davis has received information to the effect that Nicola Tesla, the celebrated electrical experimentist and inventor will be in Colorado Springs within a few weeks.

The experiment station erected by Mr. Tesla on Knob hill about two years ago, is still in as good condition as it was when he left it, and if he comes here no may decide to conduct further experiments. The station here has been in charge of two watchmen ever since Mr. Tesla returned to the east and everything has been kept in perfect trim ready for his return.

The station here was used by Mr. Tesla in his wireless telegraphy experiments.

The New York Times Novermber 24, 1903

HOLDS TESLA'S PATENTS GOOD.

Validity of Devices Passed on by an Ohio Judge.

Special to The New York Times.

CINCINNATI, Nov. 23.—The validity of two patents granted to Nicola Tesla, the famous electrical inventor, was under consideration before Judge Thompson of the United States District Court to-day. He held that both patents were good, and are the property of the Westinghouse Electrical and Manufacturing Company of Pittsburg.

One is for the electrical transmission of power, and the second is a method of operating motors.

The Westinghouse Company in 1901 brought suit against the Dayton (Ohio) Fan and Motor Company, asking that it be restrained from manufacturing these appliances, and that damages be granted the Westinghouse people for the injury sustained by the manufacture of these devices by the Dayton Company.

THE
ELECTRIC CLUB JOURNAL

VOL. I. FEBRUARY, 1904. No. I.

GEORGE WESTINGHOUSE

Response to a Toast at the Dinner in Connection with the Annual Meeting of the District Managers of the Westinghouse Electric and Manufacturing Company at the Duquesne Club, Pittsburg, December 3, 1903.

By Frank H. Taylor, Vice-President

GEORGE WESTINGHOUSE:

Mechanic; Friend of Labor;
Inventor; Tireless Organizer;
Financier; Founder of Enduring Industries.

What all the world knows needs only to be mentioned to you who are his associates in business:

The revolution in railroading wrought by the developed air brake;

The foresight that recognized the importance of the discovery of natural gas in the Pittsburg district and controlled its development;

The resourcefulness and ingenuity which won the great victory at the World's Fair in Chicago;

The courage that triumphed over the difficulties of a financial crisis;

The power that has led the unparalleled increase in the Westinghouse industries which, started but a few years ago, are now appalling in their size and extent;

The executive ability that has been the controlling factor in these interests, so numerous that no one here in an hour's time could write out a complete list of them.

These interests have grown so large and the number of responsible officers has become so great that Mr. Westinghouse is not as intimately known to you as I should desire, and as I am sure he himself would desire, if it were possible.

Some of the peculiarities which have aided him to acquire his present position may be illustrated. For example, it is unusual for an inventive genius to be so perfectly open-minded to the inventions of others. I sometimes think he is as happy over the discoveries of other minds as though they were his own. He has found a means for the development of new inventions all his life. Great intellects have worked for him, been encouraged and protected by him. I names at random: Shallenberger, Tesla, Scott, Parsons, Nernst, Ruud, Cooper Hewitt, Thomas, Davis, Bremer, Lamme, Wurts, Lange.

His mind is constantly reaching out into the future, and after one has been much with him it becomes practically impossible to live altogether in the present, because there is brought to view at every turn possibilities of new things yet undeveloped which are to serve future generations at a time when the world has advanced far beyond its present stage. The imagination is constantly stimulated and interest kept alive by the new principle that is struggling on towards definite shape.

There is always present the evidence of good will toward every one; a quick appreciation of the good points of other people. In the course of his life he has been forsaken by friends who lacked courage to follow him, and in its main crisis he was greatly hampered by heart-breaking incidents of this kind. Yet no one has ever heard him say an unkind word of these men. His foresight is phenomenal. The industries in this country have grown up even faster than seemed wise to a great many who were associated with him. They did not see the value of what he was doing as clearly as he saw it, and time alone has justified the thoroughness with which plans have been laid, buildings designed and executed. Energy and expense have not been spared upon any of his works. They have been developed in such a way that they can be extended forever.

No sooner had provision been made for this country than many of his closest friends were startled by a move upon Europe and the markets of the world. Some men have charged this move to a mere ambition to plant his name in Europe. They wondered that he should tax his resources and take upon himself the tremendous strain which has finally resulted in the great organizations and plants in England, France, Russia and Germany.

The associates who questioned his wisdom did not have his foresight and did not see that these things were necessary for the

protection of the initial developments in the United States. I give no importance to my own judgment in this matter, but Mr. Westinghouse knew that the foundations here would have been insecure had not the foreign field been entered during his period of maximum activity. We shall live to see all the effort justified, and the Westinghouse interests the world over fitting together and helping one another.

After all, what is the ultimate aim of it? Men work for wealth, for social position, for the esteem of professional associates, for the applause of the world. These things may be nominated ambition and of that all men must plead guilty.

In the case of Mr. Westinghouse the aim is not immediate wealth. He has done his work too thoroughly to have that as his goal. From my closer observation of him I should determine that he meant to leave a monument upon the earth that shall be strong enough to stand alone without consolidation with other interests, and that shall bear his name for a hundred years. Napoleon's words to his brother when he was made ruler of Spain were: "My one word of advice to you—be master," and I anticipate that the Westinghouse interests will be master of anything they associate with during the next century. By that time the appreciation of what Mr. Westinghouse has done for the world will be clearer and more just than it is to-day.

Great men cannot be compared one with another. They are moulded by circumstances and no two are alike any more than two great trees are alike, yet no man is great who lacks certain essential qualities: First, he must at all times be just, and in the case before us this quality has prevailed. A great nature shows itself by being kind and considerate. The underlying sweetness of his spirit is illustrated by the watchword that he uses among all his interests—a constant repetition of a plea for harmonious action. Other virtues are shown by the cleanness of his life. You who have, at times, worked for other kinds of men must know the power that comes to those who work for a clean man, and one who demands soundness of thought and expression. He is never satisfied with surface appearances, but seems to look right through to the heart. His mind is so quick that he sees the essential point in a complicated situation even before the story can be fully told to him. Once determined upon his course, he is not to be laughed out of it, frightened out of it, nor bought off.

The boundless hospitality of his home has been often mentioned, but when one has had the opportunity repeatedly of seeing him there, he is impressed with the uniform cheerfulness of the man and of his sustained interest in every detail of household life. I saw somewhere a letter from a wife written upon the birthday of her middle-aged husband. In the letter this sentence appeared: "To me, you will always be my young lover." This one sentence defines Mr. Westinghouse in his home.

To one associated with him in business, it has often seemed that to be loved of the man is an aim worthy of a life of devotion to his interests.

I have referred to the fact that all men have their ambitions. Every one here is anxious for a broader field, and I am sure will attain to it. Yet every one of us has arrived at an age when we can make a fairly good estimate of our probable attainments. This is our annual dinner and it is a good time to take account of stock. My judgment is that there is in our organization an opportunity for every man to be satisfied. For myself, first of all, I want a conscience void of offense. Next, I want to leave some record in the world for my family. I should like to be remembered as one who has accomplished something. I, too, want to leave a monument. My ambition is not for popularity, nor for fortune. I am satisfied if I leave my children the inheritance that their father had been able to catch something of the spirit of a great leader, and that he had been somehow useful in perfecting that leader's work and in developing his plans. For me it shall be enough that I served under George Westinghouse; that I was accounted one of his efficient lieutenants.

The Annual Dinner of the American Institute of Electrical Engineers.

The annual dinner of the American Institute of Electrical Engineers will be held in the main ball room of the Waldorf-Astoria, New York City, Thursday, February 11, 1904, at 7 P.M., precisely. The guest of honor will be Mr. Thomas Alva Edison, and it is expected that an opportunity will be given to meet Mr. Edison at an informal reception, at half-past 6. This dinner will commemorate the twenty-fifth anniversary of the introduction of the incandescent lamp, and will also celebrate Mr. Edison's birthday. Upon this occasion will also be presented the deed of gift of the Edison Medal Association, which has raised a fund of several thousand dollars.

The following guests have accepted invitations: Mr. Ambrose Swasey, president American Society of Mechanical Engineers; Dr. A. R. Ledoux, president American Institute of Mining Engineers; Col. Robert Clowry, president Western Union Telegraph Company; Mr. George G. Ward, vice-president and manager Commercial Cable Company; Mr. W. H. Baker, vice-president Postal Telegraph Cable Company; Mr. John Fritz, founder Bethlehem Steel & Iron Works; Mr. W. H. Fletcher, president Engineers' Club; Mr. A. B. Chandler, president Postal Telegraph-Cable Company.

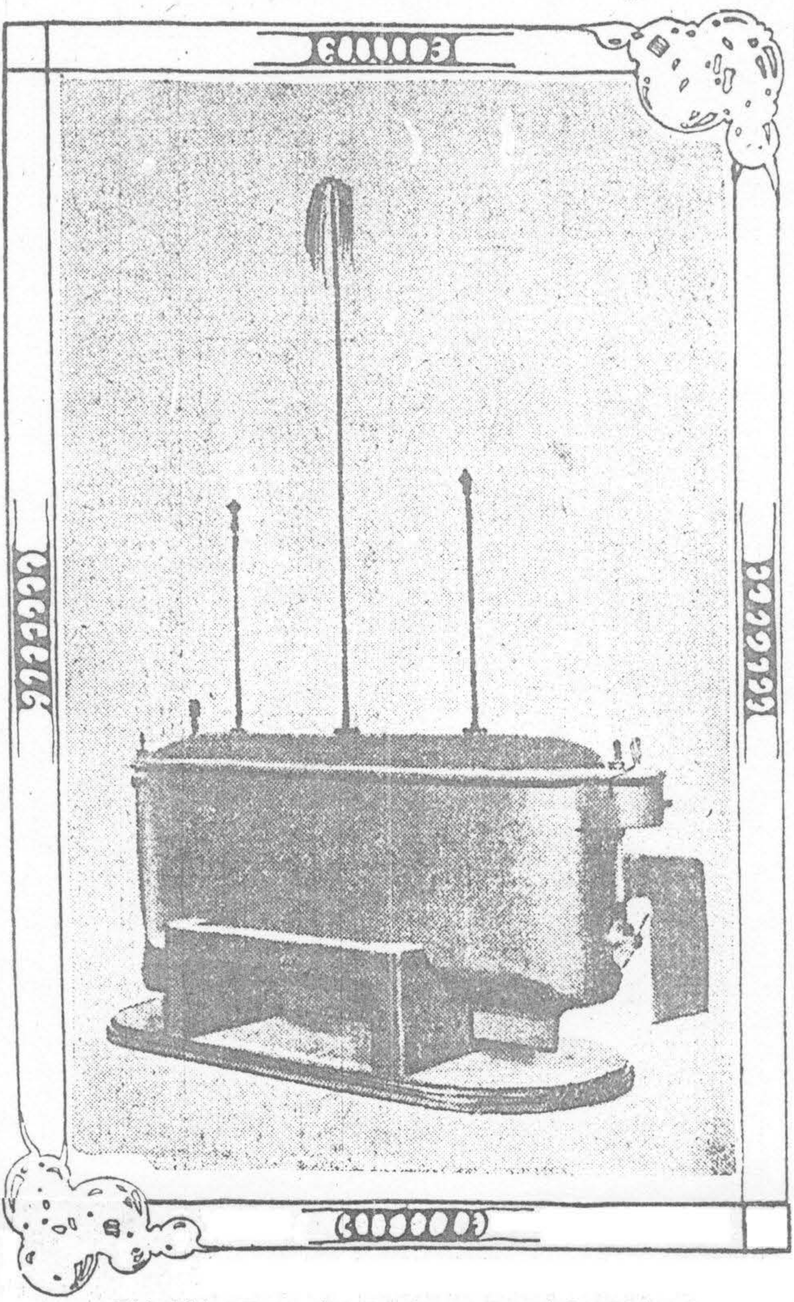
Autographed souvenir menus have been prepared containing a colored photogravure of Mr. Edison and two original poems prepared by Mr. R. R. Bowker. The exercises will be as follows: Salutatory address by President B. J. Arnold; presentation of the medal fund and deed of gift by Mr. Samuel Insull, chairman of the Edison Medal Association; acceptance of same on behalf of the Institute by Dr. A. E. Kennelly, of Harvard University, past president; address on behalf of the colleges and universities by Prof. Cyrus F. Brackett, of Princeton University; address on behalf of the Association of Edison Illuminating Companies by President J. B. McCall; address on behalf of the National Electric Light Association by President Charles L. Edgar.

Mr. Edison has flatly declined to speak, but in response to the toast in his honor has agreed to send from the table a telegraphic acknowledgment. It is a great many years since he used the key. He will use one of the original quad sets built by him for, and loaned by the Western Union Telegraph Company. The message will be received in the banquet hall on a Postal quad of latest date by President A. B. Chandler, of the Postal Telegraph Cable Company, and will then be read to the audience. These arrangements are in the hands of Mr. C. P. Bruch, assistant general manager of the Postal system, and Mr. J. C. Barclay, chief engineer of the Western Union system. A number of special cable messages and telegrams will also be received at the same time.

The seating arrangements provide for the accommodation of eight persons at each table. Orders for seats should be sent in at once and should be accompanied by cash or check, payable to Mr. Ralph W. Pope, secretary. Price of tickets, without wine: Gentlemen, $7; ladies, $5; admission to galleries, $1. In order to secure accommodation, responses should reach Mr. Pope not later than February 9, 1904, 95 Liberty Street, New York. Mr. Arthur Williams, chairman of the committee on decorations, has made elaborate preparations for ornamenting and illuminating the ball room, and the effect will be very pretty and appropriate.

A Striking Tesla Manifesto.

We reproduce herewith in slightly reduced fac-simile the first page of a four-page circular which has been issued this week by Mr. Nikola Tesla in a large square envelope bearing a large red wax seal with the initials, "N. T." At the back of the page which we reproduce is given a list of 93 patents issued in this country to Mr. Tesla. The fourth page is blank. The third page has a little vignette of Niagara Falls and is devoted to quotations from various utterances of Mr. Tesla. The first of these is from his lecture delivered in 1893 before the Franklin Institute and the National Electric Light Association, as to transmission of intelligible signals and power to any distance without the use of wires. The second quotation is from his article on the problem of increasing human energy, which appeared in the *Century Magazine* in June, 1900, dealing with virtually the same subject. The third item quotes from his patents, Nos. 645,576 and 649,621, dealing with the transmission of electrical energy in any quantity to any distance, with transmitting and receiving apparatus movable as in ships or balloons. The circular is an extremely interesting one. It is most sumptuously got up on vellum paper and altogether constitutes a manifesto worthy of the original genius issuing it. It is to be gathered from the circular that Mr. Tesla proposes to enter the field of consulting engineership, in which he already has enjoyed an extensive connection here and abroad.



PAGE FROM CIRCULAR SHOWING TESLA TOWER, WARDENCLIFFE, LONG ISLAND.

The New York Journal And American February 13, 1904

DID JAPANESE USE WIRELESS TORPEDO?

Tesla Says He Gave the Details of His Invention to the Mikado's Men Three Years Ago.

Did This Torpedo Destroy Russia's Ships?

Photograph of a torpedo invented by Nicola Tesla in accordance with a principle discovered by him. It contains automatic propelling machinery and can be set free under the water and directed by wireless electrical waves in any direction and to any distance.

Reports of Japanese victories have hinted at the use against Russian battleships of a mysterious, wireless, dirigible torpedo. Such a craft was invented four years ago by Nicola Tesla, of this city, the principle of it being his own discovery. Mr. Tesla and Lewis Nixon are now perfecting the machine. Mr. Tesla was asked yesterday by an "AMERICAN" reporter whether it could be that Japan had destroyed the Russian ships with his torpedo. He answered that while he had no information on the point, it was quite likely.

"I took out no patents in Japan," said he. "Of course, the Japanese are extremely skillful people, and the fact is that several officials of their Government and a number of scientific men visited me three years ago, and to these I gave the most complete information on all the patents. I gave to one of their men copies of my patents also.

"It would not surprise me if by this time they had succeeded in producing models of my automaton. Naturally, they would be more or less crude, but even if so they would be sufficient to accomplish their purpose.

Mr. Tesla's machine is not a mere engine of war, nor need it be used in the water exclusively. He can, with his apparatus, send an automobile overland on missions of war or peace, for pleasure or business. His idea in putting forward the machine as an implement of war is to make war bloodless by making its possibilities so terrible that all battles will be between mere automatic machines.

After a battle is fought between these machines, the nation deprived of its automatons will be forced to surrender because it will be so absolutely defenceless. It would be madness for it to attempt further resistance.

"I attained the result aimed at," says Mr. Tesla, "by means of an electric circuit placed within the boat, and adjusted, or 'tuned,' exactly to electrical vibrations of the proper kind transmitted to it from a distant 'electrical oscillator.' This circuit, in responding, however feebly, to the transmitted vibrations, affected magnets and other contrivances, through which were controlled the movements of the propeller and rudder, and also the operations of numerous other appliances.

"By the simple means described, the knowledge, experience and judgment—the mind, so to speak—of the distant operator were embodied in that machine, which was thus enabled to perform all its operations with reason and intelligence. It behaved just like a blindfolded person obeying directions received through the ear."

Mr. Tesla and Mr. Nixon are waiting with intense impatience to hear certain news that the Tesla torpedo is being used by the Japanese. No other nation has the machine, and if it prove that Japan has perfected the terrible engine it practically makes her master of the sea, for no navy, however powerful in units or numbers, could hope to escape complete destruction with these submarine monsters directed against it.

Injunction on Tesla Patents Denied.

Judge Seaman of Milwaukee has decided the motion for injunction made under Tesla patents Nos. 381,968, 381,969, 382,280 and 382,281, which are the Tesla polyphase patents. The suit was brought against the National Electric Company of Milwaukee, and the device involved was that company's polyphase-synchronous motor. Judge Seaman found that the complainant has not made out such a case of infringement as is required in a matter of this kind. The case was argued on January 6th and 7th by Thomas B. Kerr and Parker W. Page for the Westinghouse Electric and Manufacturing Company, complainant, and E. H. Bottum and Charles A. Brown for the defendant. This is the first adverse decision that has been rendered upon the broad Tesla patents involved in this suit.

Tesla Patent Decision.

Judge Seaman of the United States Circuit Court of the Eastern District of Wisconsin, has handed down a decision on a motion for a preliminary injunction against the National Electric Company, applied for on the grounds that a polyphase synchronous motor manufactured by that company infringed four Tesla patents granted May 1, 1888, two of these being fundamental patents and two on specific means. The injunction was denied on the grounds that previous decisions sustaining Tesla patents did not pass upon the question whether they also covered polyphase synchronous motors.

Judge Seaman discussed the several opinions sustaining Tesla patents, beginning with that of the New England Granite Company case, and concluded that the terms of these only apply to polyphase non-synchronous motors. The sweeping opinion in the New England Granite Company case he considers must be treated as modified by subsequent opinions, and he quotes Judge Brown to the effect that Tesla discovery was not broadly the use of alternating currents of different phase with an ultimate object of rotating any shaft. No case involving the use of a motor operated in synchronism has been brought to final hearing, though such use constantly appeared, while litigation was vigorously prosecuted against non-synchronous infringements—one instance being that of the continuous manufacture of synchronous motors by a defendant, who was under injunction against infringement by a non-synchronous motor in suit and this without interference until lately. The question of infringement in the present case under the fundamental facts depends upon the scope of the invention and involves a broader construction than was involved in any other prior cases, and consequently the court denied the motion for preliminary injunction.

Tesla Patents.

Judge Seaman of Milwaukee, in his decision adverse to the Westinghouse Electric and Manufacturing Company in its case against the National Electric Company asking for a preliminary injunction under a bill alleging an infringement of the Tesla patents for electrical transmission of power and for specific motors, gives the first adverse ruling on the Tesla patents. The patents in the suit are Nos. 381,968 and 382,280 for the fundamental invention, and Nos. 381,969 and 382,281 for specific means. A report of the ruling in this case was published in the Western Electrician of February 13th, but the following abstract of Judge Seaman's opinion will be of interest:

"The fundamental patents (so called) have been upheld and the scope of invention therein passed upon in several cases. They were directly involved in the New England Granite Company case in the Second Circuit, and the decree on final hearing (103 Fed., 951) was affirmed (110 Fed., 753) on appeal; both opinions are instructive, and in respect of the validity of the patents at least are deemed controlling for the purposes of this motion. Upon application for a preliminary injunction in Royal Weaving Company case, in the Rhode Island district (115 Fed., 733), the French patents of Dumesnil and Cabanellas (which were not before the courts in the first-mentioned case) were introduced, and are well considered and distinguished from the invention in suit in the opinion of Judge Brown granting an injunction. In the case against H. C. Roberts and Sangamo Electric Company, in the Eastern District of Pennsylvania, subordinate patents were involved, but Judge Archibald reviews the question of fundamental invention in an excellent opinion upon final hearing.

"The present application is governed by the settled rule in this circuit, which entitles the complainant to the benefit of these adjudications by way of presumptive right to an injunction against other infringers of the patents so upheld when the infringement is undoubted. Such rule, however, excludes the specific patents (Nos. 381,969 and 382,281) from consideration in so far as the issue of infringement rests upon the devices there shown, for the reason that neither adjudication of their validity, no public acquiescence therein, as demanded by the rule, appears in evidence. The presentation of these derivative patents in the bill does not aid the motion for preliminary injunction under the rule referred to, whatever may prove to be their bearing upon the issue of infringement at final hearing, but infringement for the purposes of the motion must be tested alone by the patents which have been adjudicated and in the light of their construction as there given, with the modifications imposed by the production of the Dumesnil and Cabanallas patents. Whether the inquiry is materially simplified by such exclusion I am not prepared to say.

"The great advance in the art which was made by Tesla's discovery is not fairly questionable, but difficulty arises, nevertheless, in ascertaining the essence of the invention when the contentions and opinions in the prior cases are read in connection with the record and arguments in the case at bar. * * *

"The defendant's machine, which is alleged to be an infringement of the patents, is used as a generator and then as a motor alternately. It is claimed that it was constructed for the purposes of a generator, but subsequently utilized to serve as a motor; that it 'always operates as a generator during the period of starting;' that 'at one instant it will be generating currents and at the succeeding instant it will be running as a motor;' that 'in both cases identically the same principles of operation are employed, and they are principles of operation which were well known in the prior art;' that as a motor it is distinctively synchronous and not self-starting, and thus neither within the adjudication cited nor within the contentions on which they were predicated. In other words, the contention is that the Tesla rotating field is not employed in the operation of the motor in the way or for the purposes of the Tesla invention. It is undisputed that the infringing motors in each of the prior adjudications were nonsynchronous; that no case involving the use of a motor operated in synchronism has been brought to final hearing, though such use constantly appeared, while litigation was vigorously prosecuted against nonsynchronous infringers, one instance appearing of continuous manufacture of synchronous motors by a defendant who was under injunction against infringement by a nonsynchronous motor in suit, and this without interference until recently. Explanations of the fact that no such case of alleged infringement has reached hearing is made on the part of the complainant, and while the explanation is not unreasonable the fact remains and must enter into consideration upon this motion.

"The question of infringement in the present case under the fundamental patents depends upon the scope of invention and involves a broader construction than was involved in either of the prior cases. I am not sure that the contentions on behalf of the complainant in the prior cases are consistent with the construction now sought to reach the alleged infringement. In this view I am not prepared to conclude that infringement appears beyond question or unreasonable. Recognizing the protection due to the owner of the patents on the strength of the decree upholding their validity and scope—of special importance under the circumstances disclosed here—I have carefully examined to that end much of the expert testimony, and while I am impressed with the force of the contention urged on behalf of the complainant as to the true advance in the art made by the Tesla discovery and the scope of invention therein, the issues now raised require hearing upon complete proofs. So considered, discussion of the merits of the present controversy is unnecessary and inadvisable, and the motion for preliminary injunction must be denied."

The Development of Alternating-Current Work in America.

By Charles Appleton Terry.

Your request for reminiscences concerning the development of the commercial alternating-current system carries one's thoughts back to the early eighties when, though the direct-current system was in fairly extensive use, the alternating current had yet to receive the serious consideration of our engineers. Looking back over this period, the names of a few individuals stand out with peculiar prominence.

It is needless to say that the personality of Mr. Westinghouse is most conspicuously interwoven with the entire development of this system. When the work of Gaulard & Gibbs was first brought to his attention, he engaged the services of one of the most prominent of the electrical engineers of that time, Franklin L. Pope, a man whose quiet, forceful work aided greatly in the successful introduction of the alternating system to a skeptical public. Mr. Pope possessed an extraordinarily resourceful mind and a retentive memory, stored with useful facts and apt information. His rare sense of humor and genial kindness of manner were combined with a persistence of will and untiring studiousness which had rendered him a recognized authority upon all electrical subjects; and to-day his publications upon telegraphy and kindred subjects are valuable works of reference. His railway signalling inventions had brought him into close association with Mr. Westinghouse, and it thus came about that in February, 1886, as a direct result of experiments made with the Gaulard & Gibbs system at Pittsburg in 1885, Mr. Pope went to England commissioned by Mr. Westinghouse to secure the American rights to the Gaulard & Gibbs system. Throughout the formative period of the system, Mr. Pope was closely identified with the patent and scientific matters involved.

The rapid march from the experimental plant of 1885, to the commercial plant installed at Buffalo in November, 1886, was largely to the credit of the engineering ability of Shallenberger, Stanley and Belfield. Within a year thereafter sixty-five plants were sold, representing a total generating capacity of 125,000 incandescent lamps. Almost immediately a strong opposition to the alternating system was developed by the partisans of the direct-current system, an opposition which though gradually lessened did not cease until the commercial advent of the rotary transformer or converter which wedded the two systems.

In the earlier days the alternating system was at first seriously handicapped by the lack of a meter and a power motor. In April, 1888, Shallenberger, while experimenting with an arc lamp, noted a peculiar action of a small coiled spring which accidentally lodged on the brass flange of the magnet spool; the spring slowly turned about its longitudinal axis. From this accidental circumstance Shallenberger within a month developed his alternating-current meter, which for nearly ten years was the principal recording meter for this system, the only other commercial one being that devised by Prof. Elihu Thomson, who also made important inventions in the alternating-current field.

The requirement of a motor was met by Tesla's discoveries, the public announcement of which was nearly coincident with the independent discovery of Shallenberger and the publication of Ferrari's work along similar lines. Tesla's discoveries, however, included the polyphase system, which lent itself more perfectly to the distribution of large power units.

There still remained the requirement of a power motor adapted to railway service, and this is now being met by the assured single-phase motors of Lamme and Steinmetz.

It would seem that as a result of this perseverance of those interested in the alternating-current system, the perfection of the detail apparatus and the growing appreciation of its possibilities, the handicap now rests upon the shoulders of the direct-current system rather than upon that using the current which Shallenberger once described as "the electric current as God gave it to us."

The Transmission of Electric Energy Without Wires.

By NIKOLA TESLA.

IT is impossible to resist your courteous request extended on an occasion of such moment in the life of your journal. Your letter has vivified the memory of our beginning friendship, of the first imperfect attempts and undeserved successes, of kindnesses and misunderstandings. It has brought painfully to my mind the greatness of early expectations, the quick flight of time, and, alas! the smallness of realizations. The following lines which, but for your initiative, might not have been given to the world for a long time yet, are an offering in the friendly spirit of old, and my best wishes for your future success accompany them.

Towards the close of 1898 a systematic research, carried on for a number of years with the object of perfecting a method of transmission of electrical energy through the natural medium, led me to recognize three important necessities: First, to develop a transmitter of great power; second, to perfect means for individualizing and isolating the energy transmitted; and, third, to ascertain the laws of propagation of currents through the earth and the atmosphere. Various reasons, not the least of which was the help proferred by my friend Leonard E. Curtis and the Colorado Springs Electric Company, determined me to select for my experimental investigations the large plateau, two thousand meters above sea level, in the vicinity of that delightful resort, which I reached late in May, 1899. I had not been there but a few days when I congratulated myself on the happy choice and I began the task, for which I had long trained myself, with a grateful sense and full of inspiring hope. The perfect purity of the air, the unequaled beauty of the sky, the imposing sight of a high mountain range, the quiet and restfulness of the place—all around contributed to make the conditions for scientific observation ideal. To this was added the exhilarating influence of a glorious climate and a singular sharpening of the senses. In those regions the organs undergo perceptible physical changes. The eyes assume an extraordinary limpidity, improving vision; the ears dry out and become more susceptible to sound. Objects can be clearly distinguished there at distances such that I prefer to have them told by someone else, and I have heard—this I can venture to vouch for—the claps of thunder seven and eight hundred kilometers away. I might have done better still, had it not been tedious to wait for the sounds to arrive, in definite intervals, as heralded precisely by an electrical indicating apparatus—nearly an hour before.

In the middle of June, while preparations for other work were going on, I arranged one of my receiving transformers with the view of determining in a novel manner, experimentally, the electric potential of the globe and studying its periodic and casual fluctuations. This formed part of a plan carefully mapped out in advance. A highly sensitive, self-restorative device, controlling a recording instrument, was included in the secondary circuit, while the primary was connected to the ground and an elevated terminal of adjustable capacity. The variations of potential gave rise to electric surgings in the primary; these generated secondary currents, which in turn affected the sensitive device and recorder in proportion to their intensity. The earth was found to be, literally, alive with electrical vibrations, and soon I was deeply absorbed in this interesting investigation. No better opportunities for such observations as I intended to make could be found anywhere. Colorado is a country famous for the natural displays of electric force. In that dry and rarefied atmosphere the sun's rays beat the objects with fierce intensity. I raised steam, to a dangerous pressure, in barrels filled with concentrated salt solution, and the tinfoil coatings of some of my elevated terminals shriveled up in the fiery blaze. An experimental high-tension transformer, carelessly exposed to the rays of the setting sun, had most of its insulating compound melted out and was rendered useless. Aided by the dryness and rarefaction of the air, the water evaporates as in a boiler, and static electricity is developed in abundance. Lightning discharges are, accordingly, very frequent and sometimes of inconceivable violence. On one occasion approximately twelve thousand discharges occurred in two hours, and all in a radius of certainly less than fifty kilometers from the laboratory. Many of them resembled gigantic trees of fire with the trunks up or down. I never saw fire balls, but as a compensation for my disappointment I succeeded later in determining the mode of their formation and producing them artificially.

In the latter part of the same month I noticed several times that my instruments were affected stronger by discharges taking place at great distances than by those near by. This puzzled me very much. What was the cause? A number of observations proved that it could not be due to the differences in the intensity of the individual discharges, and I readily ascertained that the phenomenon was not the result of a varying relation between the periods of my receiving circuits and those of the terrestrial disturbances. One night, as I was walking home with an assistant, meditating over these experiences, I was suddenly staggered by a thought. Years ago, when I wrote a chapter of my lecture before the Franklin Institute and the National Electric Light Association, it had presented itself to me, but I had dismissed it as absurd and impossible. I banished it again. Nevertheless, my instinct was aroused and somehow I felt that I was nearing a great revelation.

It was on the third of July—the date I shall never forget—when I obtained the first decisive experimental evidence of a truth of overwhelming importance for the advancement of humanity. A dense mass of strongly charged clouds gathered in the west and towards the evening a violent storm broke loose which, after spending much of its fury in the mountains, was driven away with great velocity

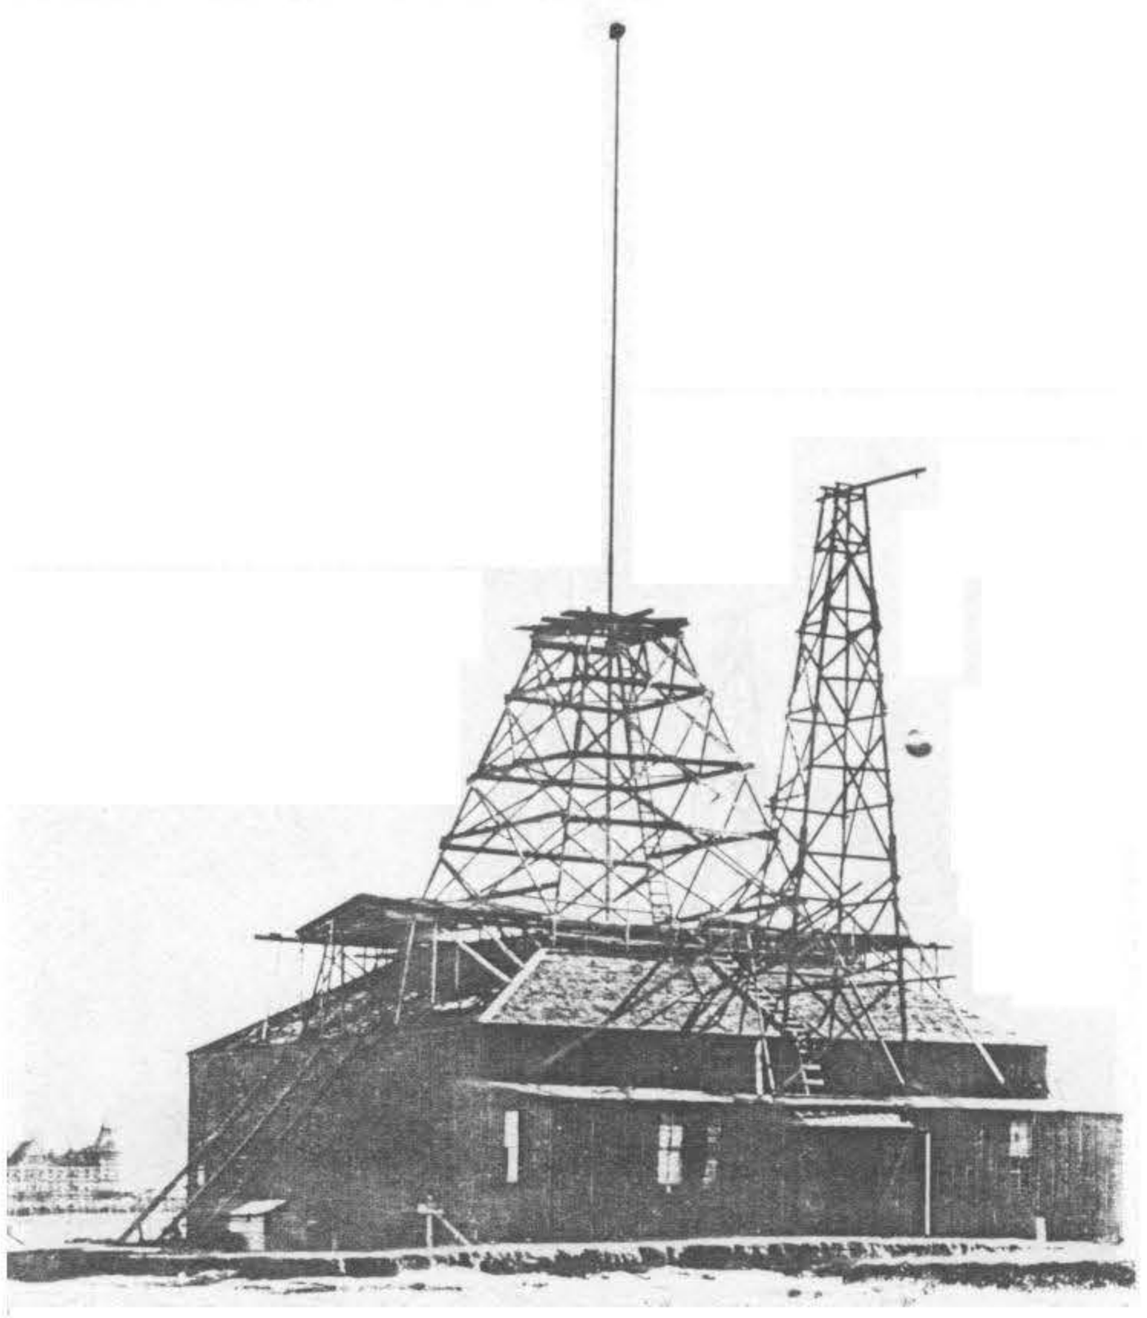


FIG. I.—TESLA EXPERIMENTAL LABORATORY, COLORADO, ERECTED SUMMER OF 1899.

(Discovery by Mr. Tesla of the Stationary Waves in the Earth was Here Made.)

over the plains. Heavy and long persisting arcs formed almost in regular time intervals. My observations were now greatly facilitated and rendered more accurate by the experiences already gained. I was able to handle my instruments quickly and I was prepared. The recording apparatus being properly adjusted, its indications became fainter and fainter with the increasing distance of the storm, until they ceased altogether. I was watching in eager expectation. Surely enough, in a little while the indications again began, grew stronger and stronger and, after passing through a maximum, gradually decreased and ceased once more. Many times, in regularly recurring intervals, the same actions were repeated until the storm which, as evident from simple computations, was moving with nearly constant speed, had retreated to a distance of about three hundred kilometers. Nor did these strange actions stop then, but continued to manifest themselves with undiminished force. Subsequently, similar observations were also made by my assistant, Mr. Fritz Lowenstein, and shortly afterward several admirable opportunities presented themselves which brought out, still more forcibly, and unmistakably, the true nature of the wonderful phenomenon. No doubt whatever remained: I was observing stationary waves.

As the source of disturbances moved away the receiving circuit came successively upon their nodes and loops. Impossible as it seemed, this planet, despite its vast extent, behaved like a conductor of limited dimensions. The tremendous significance of this fact in

the transmission of energy by my system had already become quite clear to me. Not only was it practicable to send telegraphic messages to any distance without wires, as I recognized long ago, but also to impress upon the entire globe the faint modulations of the human voice, far more still, to transmit power, in unlimited amounts, to any terrestrial distance and almost without any loss.

With these stupendous possibilities in sight, with the experimental evidence before me that their realization was henceforth merely a question of expert knowledge, patience and skill, I attacked vigorously the development of my magnifying transmitter, now, however, not so much with the original intention of producing one of great power, as with the object of learning how to construct the best one. This is, essentially, a circuit of very high self-induction and small resistance which in its arrangement, mode of excitation and action, may be said to be the diametrically opposite of a transmitting circuit typical of telegraphy by Hertzian or electromagnetic radiations. It is difficult to form an adequate idea of the marvelous

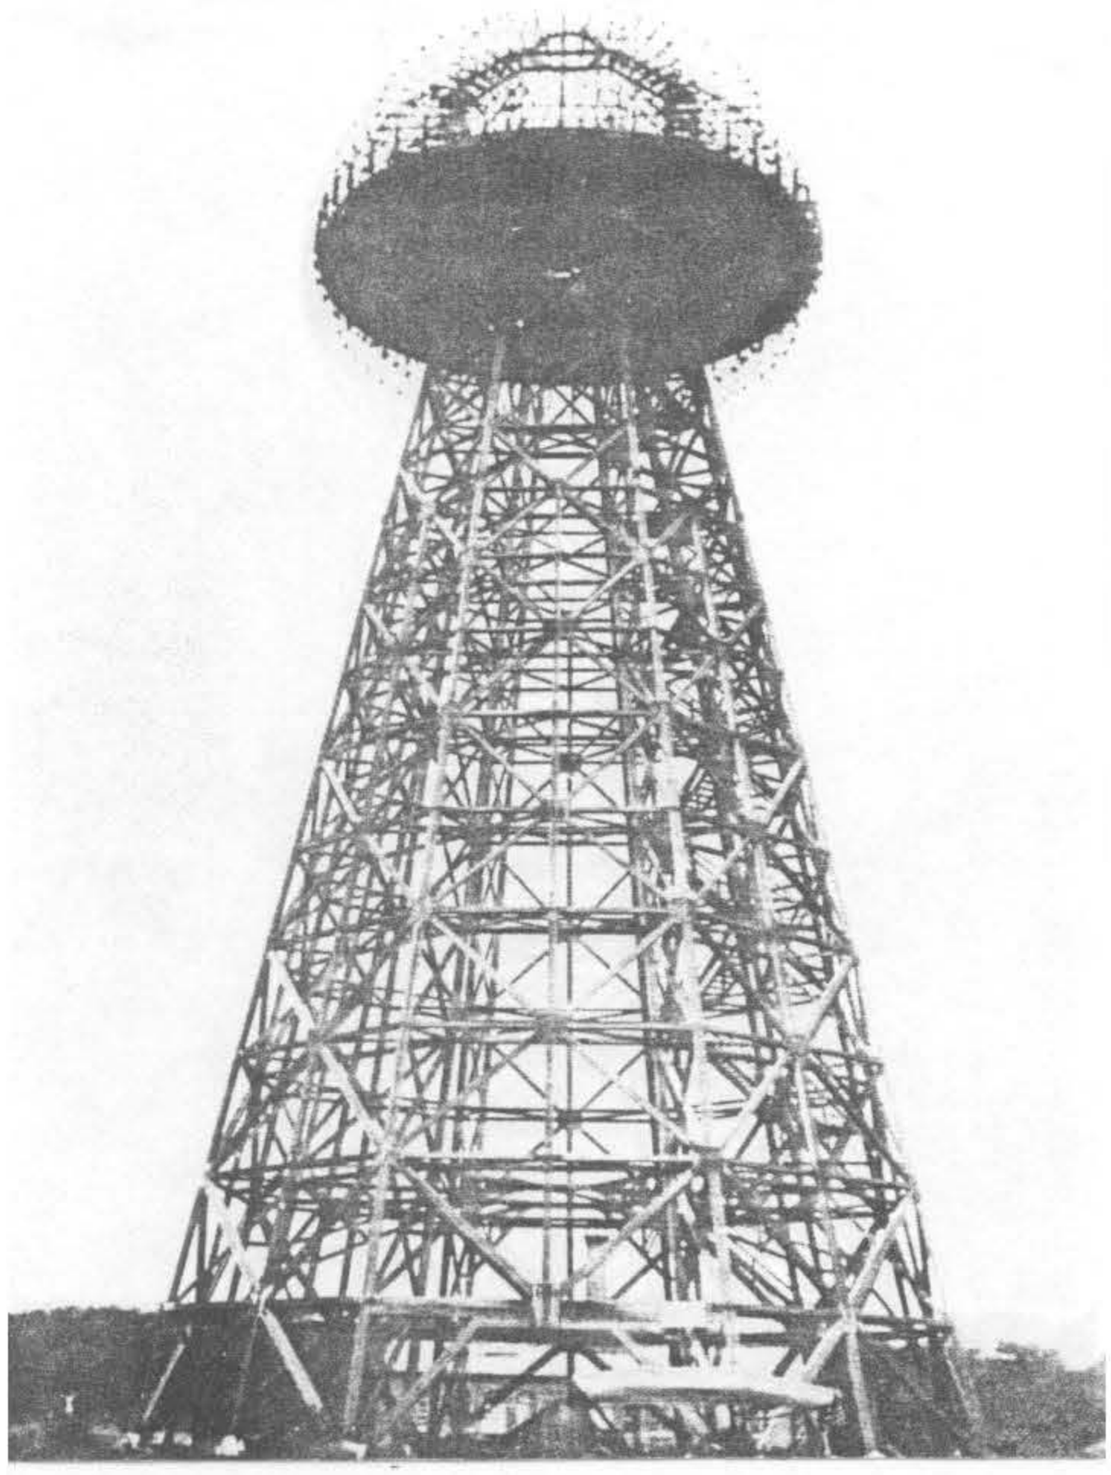

FIG. 2.—TESLA CENTRAL POWER PLANT AND TRANSMITTING TOWER FOR WORLD TELEGRAPHY, WARDENCLYFFE, LONG ISLAND, N. Y.

(Tower is a pyramid having eight sides; smallest dimensions across base, 29 meters; height, 47 meters; total height from ground to top, 57 meters; cupola on top, 20 meters diameter.)

power of this unique appliance, by the aid of which the globe will be transformed. The electromagnetic radiations being reduced to an insignificant quantity, and proper conditions of resonance maintained, the circuit acts like an immense pendulum, storing indefinitely the energy of the primary exciting impulses and impressing upon the earth and its conducting atmosphere uniform harmonic oscillations of intensities which, as actual tests have shown, may be pushed so far as to surpass those attained in the natural displays of static electricity.

Simultaneously with these endeavors, the means of individualization and isolation were gradually improved. Great importance was attached to this, for it was found that simple tuning was not sufficient to meet the vigorous practical requirements. The fundamental idea of employing a number of distinctive elements, co-operatively associated, for the purpose of isolating energy transmitted, I trace directly to my perusal of Spencer's clear and suggestive exposition of the human nerve mechanism. The influence of this principle on the transmission of intelligence, and electrical energy in general, cannot as yet be estimated, for the art is still in the embryonic stage; but many thousands of simultaneous telegraphic and telephonic messages, through one single conducting channel, natural or artificial, and without serious mutual interference, are certainly practicable, while millions are possible. On the other hand, any desired degree of individualization may be secured by the use of a great number of co-operative elements and arbitrary variation of their distinctive features and order of succession. For obvious reasons, the principle will also be valuable in the extension of the distance of transmission.

Progress though of necessity slow was steady and sure, for the objects aimed at were in a direction of my constant study and exercise. It is, therefore, not astonishing that before the end of 1899 I completed the task undertaken and reached the results which I have announced in my article in the *Century Magazine* of June, 1900, every word of which was carefully weighed.

Much has already been done towards making my system commercially available, in the transmission of energy in small amounts for specific purposes, as well as on an industrial scale. The results attained by me have made my scheme of intelligence transmission, for which the name of "World Telegraphy" has been suggested, easily realizable. It constitutes, I believe, in its principle of operation, means employed and capacities of application, a radical and fruitful departure from what has been done heretofore. I have no doubt that it will prove very efficient in enlightening the masses, particularly in still uncivilized countries and less accessible regions, and that it will add materially to general safety, comfort and convenience, and maintenance of peaceful relations. It involves the employment of a number of plants, all of which are capable of transmitting individualized signals to the uttermost confines of the earth. Each of them will be preferably located near some important center of civilization and the news it receives through any channel will be flashed to all points of the globe. A cheap and simple device, which might be carried in one's pocket may then be set up somewhere on sea or land, and it will record the world's news or such special messages as may be intended for it. Thus the entire earth will be converted into a huge brain, as it were, capable of response in every one of its parts. Since a single plant of but one hundred horse-power can operate hundreds of millions of instruments, the system will have a virtually infinite working capacity, and it must needs immensely facilitate and cheapen the transmission of intelligence.

The first of these central plants would have been already completed had it not been for unforeseen delays which, fortunately, have nothing to do with its purely technical features. But this loss of time, while vexatious, may, after all, prove to be a blessing in disguise. The best design of which I knew has been adopted, and the transmitter will emit a wave complex of a total maximum activity of ten million horse-power, one per cent. of which is amply sufficient to "girdle the globe." This enormous rate of energy delivery, approximately twice that of the combined falls of Niagara, is obtainable only by the use of certain artifices, which I shall make known in due course.

For a large part of the work which I have done so far I am indebted to the noble generosity of Mr. J. Pierpont Morgan, which was all the more welcome and stimulating, as it was extended at a time when those, who have since promised most, were the greatest of doubters. I have also to thank my friend, Stanford White, for much unselfish and valuable assistance. This work is now far advanced, and though the results may be tardy, they are sure to come.

Meanwhile, the transmission of energy on an industrial scale is not being neglected. The Canadian Niagara Power Company have offered me a splendid inducement, and next to achieving success for the sake of the art, it will give me the greatest satisfaction to make their concession financially profitable to them. In this first power plant, which I have been designing since a long time, I propose to distribute ten thousand horse-power under a tension of one hundred million volts, which I am now able to produce and handle with safety.

This energy will be collected all over the globe preferably in small amounts, ranging from a fraction of one to a few horse-power. One of its chief uses will be the illumination of isolated homes. It takes very little power to light a dwelling with vacuum tubes operated by high-frequency currents and in each instance a terminal a little above the roof will be sufficient. Another valuable application will be the driving of clocks and other such apparatus. These clocks will be exceedingly simple, will require absolutely no attention and

will indicate rigorously correct time. The idea of impressing upon the earth American time is fascinating and very likely to become popular. There are innumerable devices of all kinds which are either now employed or can be supplied, and by operating them in this manner I may be able to offer a great convenience to the whole world with a plant of no more than ten thousand horse-power. The introduction of this system will give opportunities for invention and manufacture such as have never presented themselves before.

Knowing the far-reaching importance of this first attempt and its effect upon future development, I shall proceed slowly and carefully. Experience has taught me not to assign a term to enterprises the consummation of which is not wholly dependent on my own abilities and exertions. But I am hopeful that these great realizations are not far off, and I know that when this first work is completed they will follow with mathematical certitude.

When the great truth accidentally revealed and experimentally confirmed is fully recognized, that this planet, with all its appalling immensity, is to electric currents virtually no more than a small metal ball and that by virtue of this fact many possibilities, each baffling imagination and of incalculable consequence, are rendered absolutely sure of accomplishment; when the first plant is inaugurated and it is shown that a telegraphic message, almost as secret and non-interferable as a thought, can be transmitted to any terrestrial distance, the sound of the human voice, with all its intonations and inflections faithfully and instantly reproduced at any other point of the globe, the energy of a waterfall made available for supplying light, heat or motive power, anywhere—on sea, or land, or high in the air—humanity will be like an antheap stirred up with a stick: See the excitement coming!

The New York American March 9, 1904

TESLA HAS PLAN TO DO AWAY WITH NEWSPAPERS.

With Wireless Waves of Communication, Plans to Girdle the World with Story of Happenings Far and Near

BUILDING BIG TOWER OUT ON LONG ISLAND

By means of the gigantic transmitting tower he is erecting at Wardencliff, L. I., Nikola Tesla hopes to put every newspaper in the world out of existence and to transmit telegraphic messages to the uttermost parts of the globe.

In an aritcle in the Electrical World and Engineer Mr. Tesla explains the system, and adds that "the noble generosity of J. Pierpont Morgan," who furnished the money when others did nothing but doubt, enables him to put the system in operation.

If the new system works a man may stand in the middle of the Sahara and by means of an inexpensive instrument so small that it may be carried in a vest pocket receive news of events in New York.

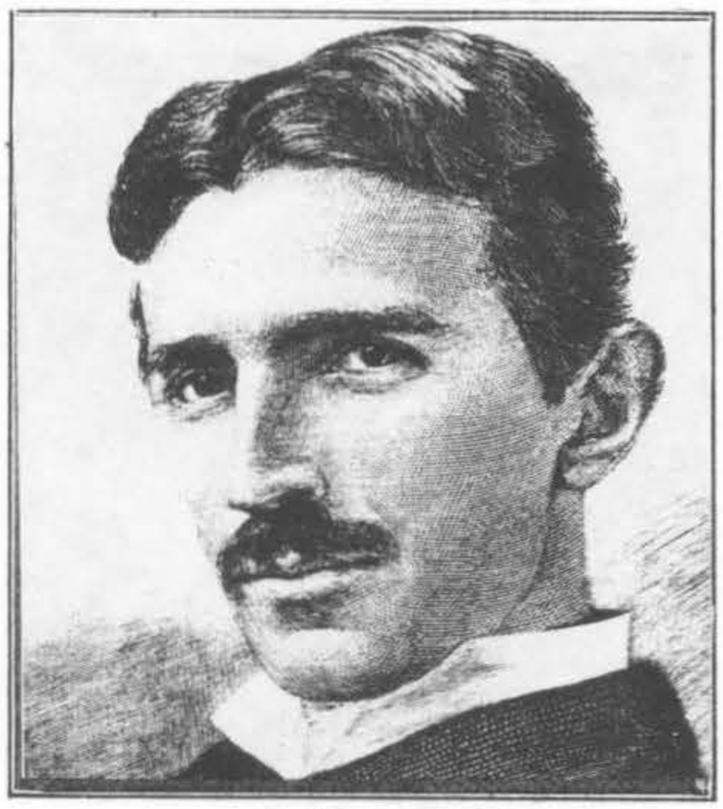
Mr. Tesla says he will magnify the stationary electric waves in the earth to such a degree of power that the globe easily can be girdled.

Earth Hears Our Whispers.

Discoveries made in Colorado, he says, showed him that the earth is a conductor of limited dimensions, and that it is possible to impress upon the whole globe the faint modulations of the human voice. Having determined these basic facts Mr. Tesla says he set himself to work to develop a magnifying transmitter which should make the modulations louder and stronger.

The tower which Mr. Tesla is building at Wardencliff is almost two hundred feet tall and is surmounted by a big cupola. The tower is in the shape of an eight-sided pyramid from the top of which will be sent the messages that are to circle the globe.

"See the Excitement Coming!"



That Mr. Tesla believes there are great possibilities in the system he is perfecting is shown by the conclusion of his article:

"When the great truth accidentally revealed and experimentally confirmed is fully recognized, that this planet, with all its appalling immensity, is to electric currents virtually no more than a small metal ball and that by virtue of this fact many possibilities, each baffling imagination and of incalculable consequence, are rendered absolutely sure of accomplishment; when the first plant is inaugurated and it is shown that a telegraphic message, almost as secret and non-interferable as a thought, can be transmitted to any terrestrial distance, the sound of the human voice, with all its intonations and inflections faithfully and instantly reproduced at any other point of the globe, the energy of a waterfall made available for supplying light, heat, or motive power, anywhere—on sea, or land, or high in the air—humanity will be like an antheap stirred up with a stick: See the excitement coming!"

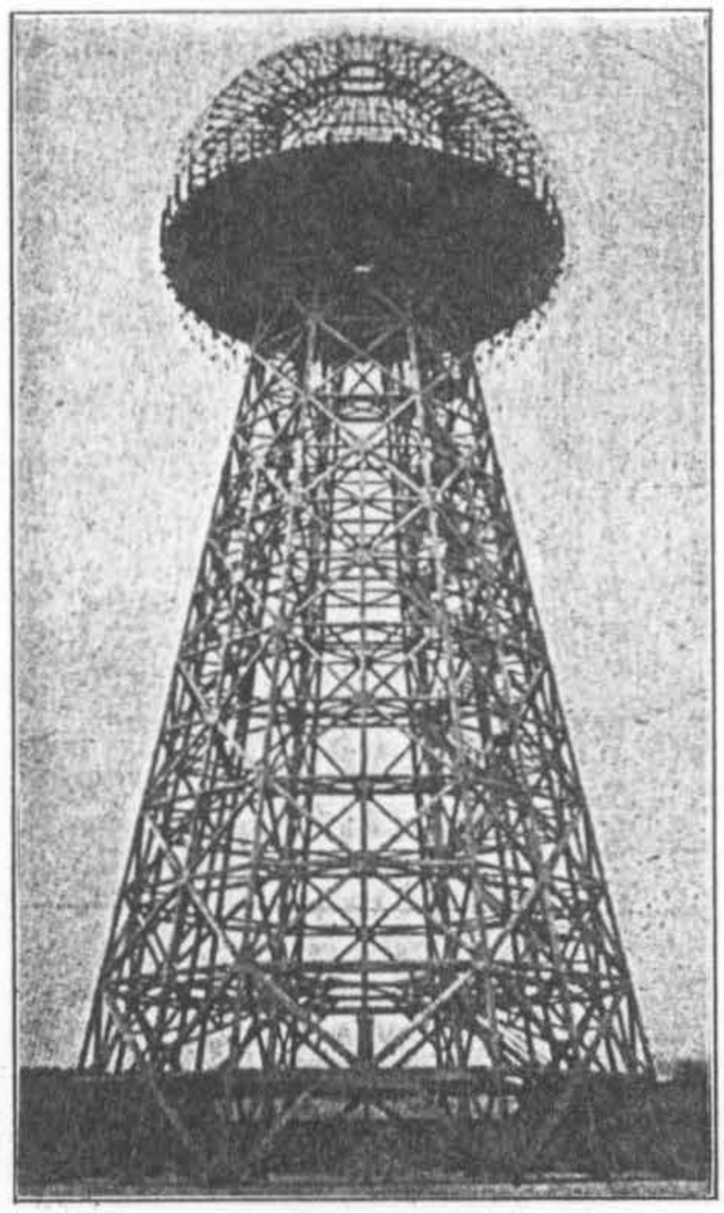
WIRELESS POWER TRANSMISSION

NIKOLA TESLA'S LATER EXPERIMENTS IN THIS FIELD—HOW THE INVENTOR EXPECTS TO REVOLUTIONIZE THE WORLD

SINCE his article in the *Century Magazine* for June, 1900, little or nothing has been heard from Mr. Tesla as to the progress of his experiments in the transmission of electrical energy without wires. It has been understood, however, that the inventor was still at work along the lines he suggested in the article referred to, and now we have in the *Electrical World and Engineer* another statement from him, showing that the inventor is just as firmly convinced as ever that the system he has devised, if not perfected, will in a short time revolutionize the world. With a realization of the stupendous possibilities in sight, Mr. Tesla says that he has been working upon the development of his "magnifying transmitter" with the sole idea of producing the best type of such an instrument:

NIKOLA TESLA

This is, essentially, a circuit of very high self-induction and small resistance which in its arrangement, mode of excitation and action, may be said to be the diametrical opposite of a transmitting circuit typical of telegraphy by Hertzian or electromagnetic radiations. It is difficult to form an adequate idea of the marvelous power of this unique appliance, by the aid of which the globe will be transformed. The electromagnetic radiations being reduced to an insignificant quantity, and proper conditions of resonance maintained, the circuit acts like an immense pendulum, storing indefinitely the energy of the primary exciting impulses and impressing upon the earth and its conducting atmosphere uniform harmonic oscillations of intensities which, as actual tests have shown, may be pushed so far as to surpass those attained in the natural displays of static electricity.



Much, Mr. Tesla adds, has been done toward making his system commercially available for the transmission of energy in small or large amounts:

The results attained by me have made my scheme of intelligence transmission, for which the name of "World Telegraphy" has been suggested, easily realizable. It constitutes, I believe, in its principle of operation, means employed and capacities of application, a radical and fruitful departure from what has been done heretofore. I have no doubt that it will prove very efficient in enlightening the masses, particularly in still uncivilized countries and less accessible regions, and that it will add materially to general safety, comfort, and convenience, and maintenance of peaceful relations. It involves the employment of a number of plants, all of which are capable of transmitting individualized signals to the uttermost confines of the earth. Each of them will be preferably located near some important center of civilization, and the news it receives through any channel will be flashed to all points of the globe. A cheap and simple device, which might be carried in one's pocket may then be set up somewhere on sea or land, and it will record the world's news or such special messages as may be intended for it. Thus the entire earth will be converted into a huge brain, as it were, capable of response in every one of its parts. Since a single plant of but one hundred horse-power can operate hundreds of millions of instruments, the system will have a virtually infinite working capacity, and it must needs immensely facilitate and cheapen the transmission of intelligence.

The Transmitter

The transmitter Mr. Tesla has completed will, we understand, emit a wave of a total maximum activity of ten million horse-power. But the "artifices" by which this result is obtained, the inventor is not ready to explain. In the power plant which Mr. Tesla is designing now he proposes to distribute ten thousand horse-power under a tension of one hundred million volts, which, he states, he "is able to produce and handle with safety":

This energy will be collected all over the globe, preferably in small amounts, ranging from a fraction of one to a few horse-power. One of its chief uses will be the illumination of isolated homes. It takes very little power to light a dwelling with vacuum tubes operated by high-frequency currents and in each instance a terminal a little above the roof will be sufficient. Another valuable application will be the driving of clocks and other such apparatus. These clocks will be exceedingly simple, will require absolutely no attention, and will indicate rigorously correct time. The idea of impressing upon the earth American time is fascinating and very likely to become popular. There are innumerable devices of all kinds which are either now employed or can be supplied, and by operating them in this manner I may be able to offer a great convenience to the whole world with a plant of no more than ten thousand horse-power. The introduction of this system will give opportunities for invention and manufacture such as have never presented themselves before.

THE TESLA TRANSMITTING TOWER AT WARDENCLYFFE, L. I., HEIGHT, 175 FEET

It was in Colorado that Mr. Tesla first became impressed with the possibilities of experimentation along the lines he has lately pursued, but the perfection of his apparatus has been carried on at a plant established on Long Island, the picture on this page showing the transmitting tower erected at this plant. No detailed description of it is given in the article from which we are quoting. Mr. Tesla states that he has been greatly assisted by Mr. J. Pierpont Morgan. The inventor continues:

Knowing the far-reaching importance of this first attempt and its effect upon future development, I shall proceed slowly and carefully. Experience has taught me not to assign a term to enterprises the consummation of which is not wholly dependent on my own abilities and exertions. But I am hopeful that these great realizations are not far off, and I know that when this first work is completed they will follow with mathematical certitude.

When the great truth accidentally revealed and experimentally confirmed is fully recognized, that this planet, with all its appalling immensity, is to electric currents virtually no more than a small metal ball and that by virtue of this fact many possibilities, each baffling imagination and of incalculable consequence, are rendered absolutely sure of accomplishment; when the first plant is inaugurated and it is shown that a telegraphic message, almost as secret and non-transferable as a thought, can be transmitted to any terrestrial distance, the sound of the human voice, with all its intonations and inflections faithfully and instantly reproduced at any other point of the globe, the energy of a waterfall made available for supplying light, heat, or motive power, anywhere—on sea, or land, or high in the air—humanity will be like an ant-heap stirred up with a stick.

SUGGESTIONS FOR PRODUCING HIGH-FREQUENCY CURRENTS AND SOME OF THEIR PHENOMENA.

BY EDWIN F. NORTHRUP AND ELLIOTT WOODS.

Inclination and circumstances have led the writers of this article to construct and play, rather than experiment in a logical and scientific manner, with apparatus of various forms for producing high-frequency currents. As the work has always been fascinating, and often instructive, even if not commercially valuable, it is thought a sort of narrative description of what we have done with high-frequency apparatus and how we constructed it and the phenomena we observed, would not be without interest to electricians interested in the laws and manifestations of electric forces.

The most difficult thing to realize by any artificial means is a strictly constant condition; be it a constant temperature, a constant illumination, a constant tone, a constant current or a constant motion. Nature left to herself tends ever to change, mutations being in general rhythmical. The most striking illustration of this tendency of Nature to a periodic variation which has been recently observed is seen in the action of a Wehnelt interrupter.

When one observes how a violin bow drawn smoothly over the string starts it into vibrations, or how a wet cork rubbed upon a window pane produces a shrill note, or a rotating wheel slightly out of balance sets up violent vibrations, and many other similar phenomena, the action of a Wehnelt interrupter, which acts upon the constantly applied electromotive force to throw the current into rapid pulsations, could certainly have been expected and might have been prophesied.

The movements of electricity in Nature as seen in lightning, in earth currents and in Northern Lights, are fluctuating or oscillating motions. It has been by the exercise of special ingenuity that, through artificial means, direct and constant electric currents have been obtained.

When an electric current flows with perfect uniformity in a circuit the concomitant phenomena are few indeed compared with the phenomena which arise when the current becomes a changing current, varying in magnitude or alternating in direction. A constant direct current is uniformly distributed over the cross-section of the wire, its external inductive effects are nil, and special contrivances must be employed to make evident its very existence. Alternate the current, the more rapidly the more striking the phenomena, and numerous effects external to the circuit are observed. The current is no longer evenly distributed over the cross-section of the wire, but crowds toward its surface until, when the variations are rapid enough, a tube having a thin wall will convey as much energy as if it were a solid rod. With the direct constant current the flow of the current can be calculated by Ohm's law. When the current alternates slowly the calculation can still be made by substituting impedance for resistance, but when the alternations reach a frequency that obtains when the electricity swings freely to and fro in the circuit, exact calculations can no longer be made, as the energy is escaping from the circuit by heat, by radiation and by other paths.

The reason that the study of high-frequency or oscillating currents is so fascinating and instructive lies in the fact

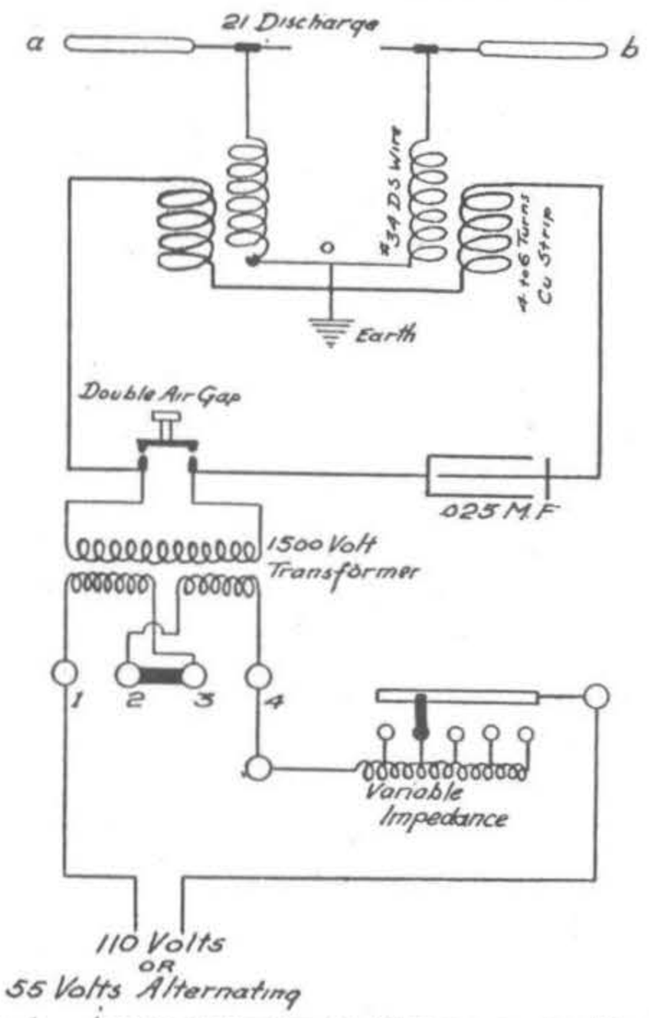

FIG. 1.—ARRANGEMENT OF CIRCUITS FOR HIGH-FREQUENCY MACHINES.

that the complexity of the phenomena which are observed forbids and makes impossible prophecies of what will happen by the aid of calculations. As we change the apparatus and vary the conditions under which we work, pleasant surprises are in store and the electrician, if he will make progress, must drop his calculus and become the observant experimenter. The writers have tried a large number of forms of apparatus and different arrangements of circuits for obtaining currents of high frequency of both low and high potential. In this article we shall confine ourselves to describing only one or two forms of apparatus and arrangements of circuits which gave best results.

The experiments of the writers have been confined to the obtaining of oscillating currents by means of the sudden disruptions of an air-gap, though there are other methods by which the equilibrium of the electricity can be disturbed and strong oscillations be obtained. In describing how the writers recently constructed a high-frequency high-potential apparatus, giving a discharge of great volume and over twenty inches in length, the essential features of design and the precautions which must be observed to obtain the best results will be brought out. It should be stated that equally good results might possibly be obtained in a number of other ways, and that the particular method adopted is only that which appeared best to the writers from theoretical considerations and many trials of different forms of apparatus.

It should be stated at the outset, and emphasized, that for obtaining the most powerful and continuous oscillations it is never necessary to resort to any device, such as a magnetic blowout, a blast of air or a mechanical contrivance for making and breaking the circuit, for disrupting the arc which, with improper arrangements, tends to form in the air-gap, weakening or destroying the oscillations. Though there are several methods by which fairly good results may be obtained, by using a source of direct electromotive force, a source of alternating electromotive force of 55 or 110 volts and of about 7,200 alternations is much to be preferred, and for the most powerful effects is necessary. There are five essential parts of a high-frequency apparatus of high potential. First, a variable impedance having as little ohmic resistance as possible and capable of carrying twenty-five or thirty amperes. This is best made by winding No. 8 wire on a core of soft iron wires. This core may be twelve inches long and two to three inches in diameter. The impedance can be made variable by bringing out any number of tapoff points, so that more or less of the turns of the winding may be used. Second, a transformer which will raise 110 volts to about 10,000 or 15,000 volts. This transformer should have a closed magnetic circuit and should be able to deliver at least two-tenths of an ampere from its high-tension winding. Third, a condenser of sufficient capacity and of dielectric strength sufficient to withstand the strain put upon it when a discharge is passing across a parallel discharge-gap of three-quarters to one inch in length. Fourth, a properly constructed double parallel discharge-gap. Fifth, a high-frequency induction coil. The last three of these pieces of apparatus will be more particularly described. Next

to the proper proportioning of the apparatus, the most essential and difficult requirement to fulfil is, that all the parts be properly insulated.

The arrangement of the circuits that the writers finally adopted in obtaining the best results with the high-frequency machine that gave over a twenty-inch discharge is given in Fig. 1. The variable impedance that is shown connected in series with a 15,000-volt transformer performs a very important function. It can not be replaced successfully by an ohmic resistance. Its action may be described as follows: when the potential has risen to a point where the double air-gap breaks down, the secondary of the transformer becomes short-circuited through the low-resistance path now formed in the double air-gap by the hot gases evolved, and if it were not for the variable impedance a rush of current would flow into the primary of the transformer and a yellow flaming arc would form in the air-gap, still further decreasing the resistance of this air-gap, and prevent the condenser from again becoming charged to a high potential. The impedance prevents this formation of the arc by holding back the sudden rush of current to the primary of the transformer. The disrupted air-gap mends and the potential of the secondary of the transformer again comes upon the condenser, charging it to its full capacity. Curiously enough, varying the amount of the impedance does not appreciably affect the length of the double air-gap that will disrupt. Increasing, however, the impedance beyond a certain point, which is fairly definite, will cause the disruptions of the air-gap, when opened a fixed distance, to quite suddenly cease. When the impedance is thrown entirely out, arcing will generally take place in the air-gap, especially if the capacity of the condenser is small and the transformer a large one, and the oscillations will become very poor or cease altogether. The variation of the impedance through wide limits produces, in a marked manner, a variation of the number of disruptions in the air-gap that take place at each alternation of the electromotive force of the source, this result being made plainly manifest in the varying thickness or volume of the high-tension discharge, as well as in the amount of current which the primary of the transformer will draw.

It will be noted that the primary and secondary of the high-frequency coils of the transformer are divided into two sections, and that the middle points of the primary and secondary are joined together and connected to the ground. The separation of the primary and secondary windings into halves is made chiefly for convenience in mechanical construction and to economize space. Connecting the lower terminals of the two sets of windings together and joining the points united to the ground, is done to protect from the high-tension discharge the insulation between the primary and secondary of the 15,000-volt transformer. If the above precaution be not taken and one side of the secondary of the high-frequency transformer be connected to ground, as is often done in certain experiments with the apparatus, one-half of the potential of the secondary of the high-frequency coil is thrown upon the insulation between the two windings of the 15,000-volt transformer.

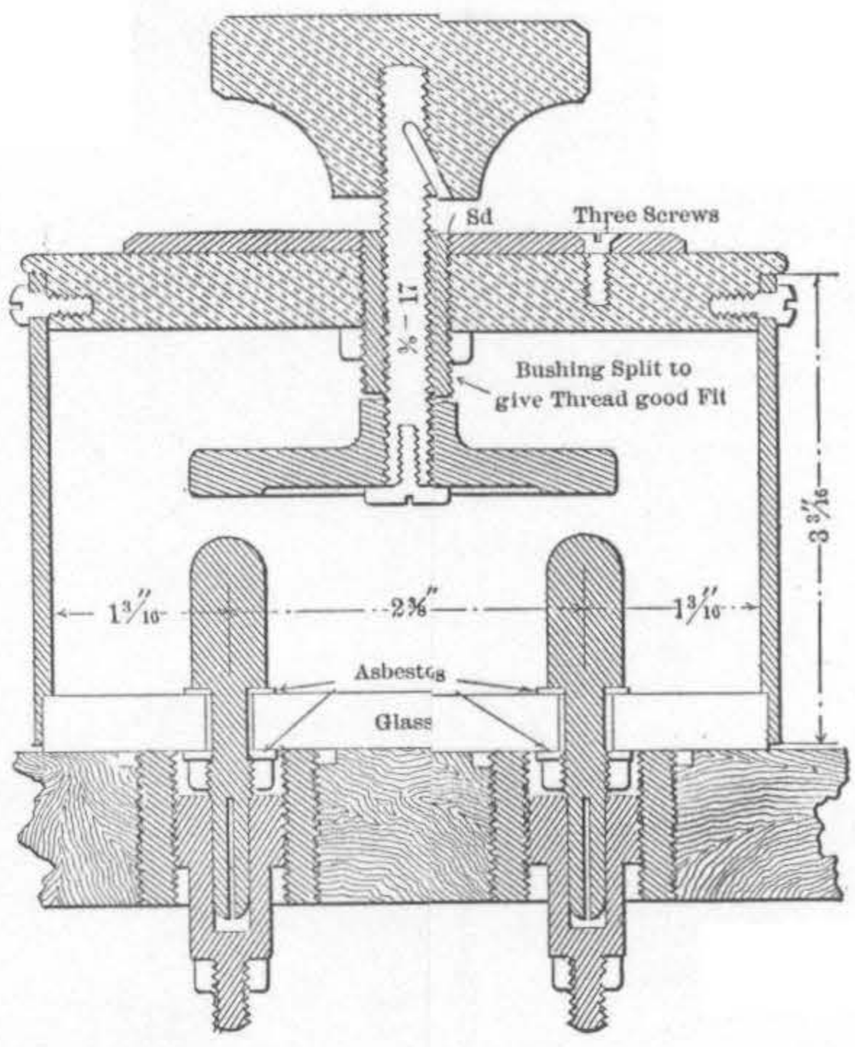

FIG. 2.—CONVENIENT METHOD OF CONSTRUCTING SPARK BOX.

Suppose the terminal *a* were connected to earth and the ground connection omitted, and the primary circuit of the 15,000-volt transformer is separated from ground by a weak insulation, then the current from the secondary of the high-frequency coil would tend to take the following course: from *a* to ground, from ground to the primary of the 15,000-volt transformer, across the insulation between the primary and secondary of this transformer to the secondary, then through the left-hand winding of the primary of the high-frequency coil to the point *o*, where the primary and secondary of the high-frequency coils are joined, through the left-hand winding of the secondary and back to *a*. Thus if the coil gives twenty inches, the insulation between the primary and the secondary of the 15,000-volt transformer may have to withstand a strain equal to a ten-inch discharge of the high-frequency coil. If the ground connection is made at *o*, it is readily seen that this strain does not come upon the insulation of the transformer.

If the primary of the transformer be made with two windings brought out to terminals 1, 2, 3, 4, the two coils of the primary may be connected in series or in parallel, thus adapting it to a 110 or 55-volt circuit. It is not convenient, however, to construct a variable impedance so as to be equally adapted to different voltages. It is not difficult to construct a high-tension transformer for this work, but it would hardly pay one to make this piece of apparatus, since it can be easily obtained in the market. The spark box, and a convenient manner of constructing it, are illustrated in detail in Fig. 2.

In this form of construction the double air-gap is easily controlled and varied in length by turning the insulated handle, which raises and lowers the circular metal disc; this can be done while the coil is in operation without danger of obtaining a shock. If the discharge-gaps are enclosed in a box, as shown in Fig. 2, the noise of the discharge will be lessened. The coil will be generally found to work better after the terminals of the gap and the air on the inside of the box have become heated from operating the coil.

The condenser is most conveniently made as follows: choose plates of the best quality of window glass, fourteen by ten

inches, and one-eighth of an inch thick. Tin-foil might answer for the metal sheet of the condenser, but a thin brass or metal sheet is much to be preferred because of its greater mechanical strength and the greater ease with which terminals may be soldered to it. The metal sheet when laid on the glass plate should reach to within one inch on the side margins of the sheet, but be kept two inches from the end opposite to which the terminal is fastened. Thus the effective area of two opposing sheets would be eight by ten inches. The condenser should be laid up in the following order: glass, a sheet of heavy paper, brass sheet, another sheet of heavy paper, glass plate, paper, brass, paper, glass, etc. Half of the brass sheets should have their ends projecting a quarter of an inch from one end of the condenser, and the other half of the brass

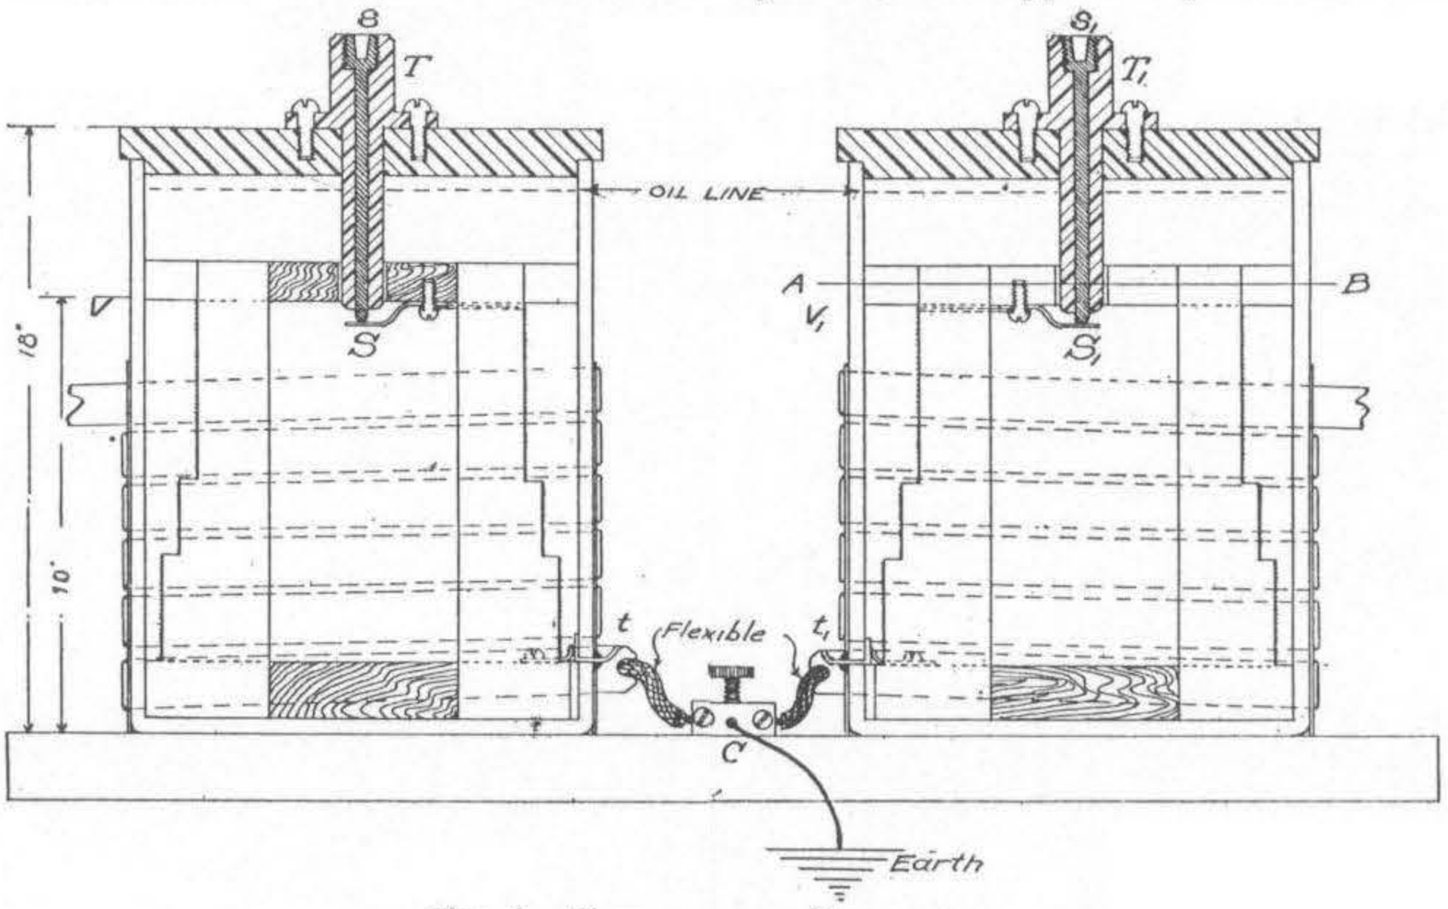

FIG. 3.—ELEVATION OF CONDENSER.

sheets, alternately placed with the first half, should project in a similar manner from the other end of the condenser. The terminals are, of course, soldered to the projecting ends of the sheets, which are bent down to lie flat and slightly overlap at each end of the condenser. To make this condenser so that it will not break down, it should be laid up under oil, care being taken that no air bubbles get in between the plates. The plates may be held in position by means of a wooden frame, and if the condenser be lifted quickly out of the oil in which it was stacked and placed in its permanent box, and the space between the condenser and its box be filled with melted paraffin, a very strong and dry condenser will be obtained, which will not break down with a one-inch discharge across a parallel gap. The capacity of such a condenser, made of forty plates of glass, is about 0.025 microfarad and is very well adapted for the production of very heavy high-frequency discharges. The writers believe that the particular form given to their high-frequency coil is the most efficient that can be built and that it is somewhat novel, and so we will describe its construction with more detail.

Fig. 3 gives in section and elevation the general form of the design adopted. Fig. 4 is a section on the line AB, of one of the halves of the coil, the two halves being identical. V and V_1 of Fig. 3 are two vessels having the relative dimensions indicated in the figure. These vessels may be of glass, hard rubber or compressed paper. The vessels employed by the writers were made of glass. The primary of the high-frequency coil should preferably consist of about four turns of insulated copper strip wound upon each of the two vessels, the two windings being joined together by a flexible connector C. A convenient way of holding the windings in place is to wind them upon a cardboard cylinder which will just fit over the glass cylinder, the copper straps of which the windings are made being fastened to the cardboard cylinders by being sewed to the cardboard with a strong thread. If the copper strap is insulated with tape or ribbon, the turns can come quite close together; if not insulated they must be kept about one-eighth of an inch apart. By adopting the arrangement shown, the highest possible insulation can be secured for the high-tension secondary winding by filling each of the two vessels nearly to the top with thin paraffin oil. The thinner and better the quality of the oil, the better the insulation secured. If the apparatus is located in a place where there is no fear of fire, the highest possible insulation is secured by the use of kerosene oil. The construction of the secondary coil requires considerable care to obtain the highest efficiency and perfectly secure insulation. The dimensions of the secondary should be proportioned about as shown in Fig. 3. The best way to form a framework on which to wind the wire of the secondary coil is to take two circular boards of hard wood which will just fit on the inside of the glass vessels and make in these boards a dozen or more radial slots one-quarter of an inch wide as indicated in Fig. 4. Hard rubber pieces should then be cut out, having the shape shown in Fig. 3, and these be inserted tightly in the radial slots of the two circular boards. By this means a tapered polygon is formed, upon which the secondary winding may be wound. This winding may be made of double silk-covered No. 34 copper wire, the turns should be laid on evenly and close together, great care being exercised that no single turn shall cross over its neighbors. After the winding is completed, it should be ended off with terminals of heavier wire and the whole be given a thick coating of shellac. This must be allowed to become thoroughly dry before the coil is used. A small hole may be drilled in the bottom of each of the glass vessels t and t_1, through which one end of each of the terminals may be passed and then be fastened to the middle point between the two primaries. The holes can be stopped up with cement so the vessels will not leak oil. Heavy terminals mounted in hard rubber can be fastened in circular

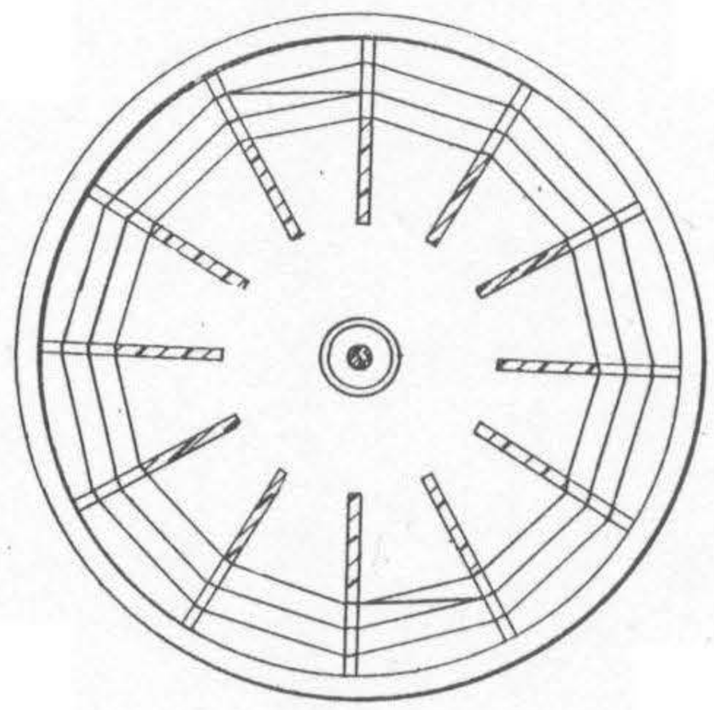

FIG. 4.—SECTION OF CONDENSER.

covers that rest on the tops of the two vessels and make automatic connections with the two terminals of the secondary by means of spring contacts as at S and S_1. One suitable form of construction is plainly shown in Fig. 3. One must be cautioned to make the circular covers of the two vessels of some perfectly insulating material, as hard rubber, otherwise brush discharges and streamers will continually pass up the outside surface of the glass vessels, the discharge attempting to take place between the primary and the terminal in the centre of the cover.

The terminals between which the high-frequency discharge is to pass may consist of balls or points which can be attached to the tops of the permanent terminals passing up through the centres of the covers. As the two halves of the high-frequency coil are independent of each other, being merely joined together by a flexible connector, the halves of the coil can be moved closer together or farther apart, according to the length of discharge which one wishes to obtain.

(To be concluded.)

SUGGESTIONS FOR PRODUCING HIGH-FREQUENCY CURRENTS AND SOME OF THEIR PHENOMENA.

(*Concluded.*)

BY EDWIN F. NORTHRUP AND ELLIOTT WOODS.

Two views, reproduced from photographs, of two coils constructed on the general lines described above are illustrated in Figs. 5 and 6. The coil shown in Fig. 5 gave a very good twenty-inch discharge. The terminals in the picture, Fig. 5, are shown twenty and one-quarter inches apart, from which standard of reference the reader can determine the other dimensions of the apparatus. The coils shown in Figs. 5 and 6 had their secondaries wound on glass jars which set on the inside of larger glass jars around which the primary coils are wound. The construction as indicated in Fig. 3 would, however, if followed, have been somewhat more efficient. The primary turns, as indicated above, should preferably be made of copper strip, as the high-frequency currents in the primary coils are chiefly confined to the surface of the conductor and by using copper ribbon instead of round wire as actually used, it is possible to surround a larger portion of the secondary windings without increasing the number of primary turns.

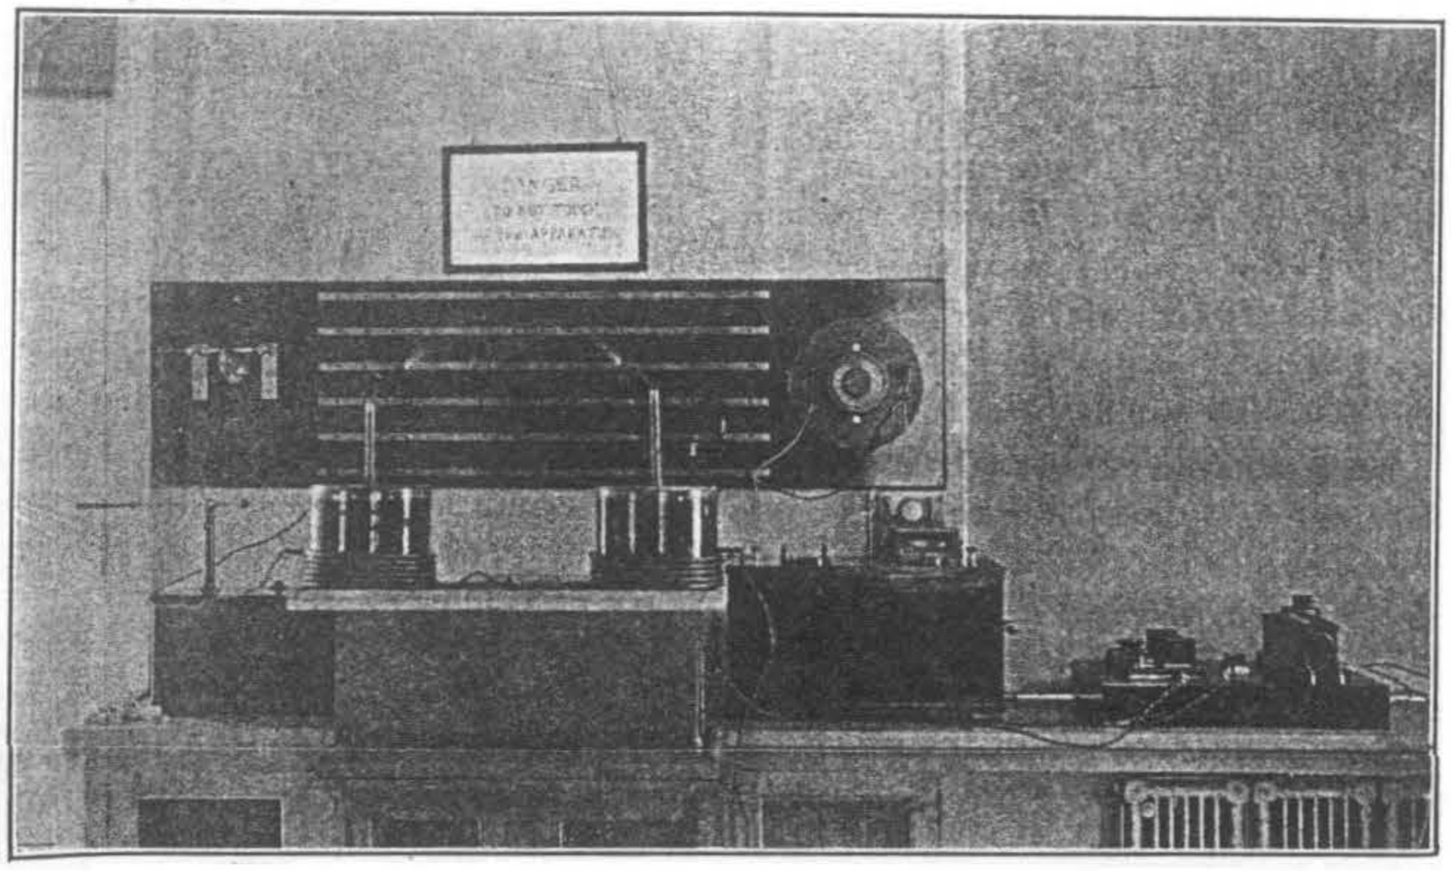

FIG. 5.—COIL FOR TWENTY-INCH SPARK—SUGGESTIONS FOR PRODUCING HIGH-FREQUENCY CURRENTS.

Experiments with the coils illustrated in Figs. 5 and 6 showed that for obtaining the maximum length of discharge a certain number of primary turns were required. For the coil shown in Fig. 6 four turns on each half seemed to give the best result. The efficiency of the high-frequency coil in regard to length and volume of discharge is greatly increased when the leads to the primary windings, or, in other words, the connecting wires in the circuit in which the electricity oscillates, are kept as short as possible. The discharge from a high-frequency coil will vary in volume, as well as in length, very greatly, according to the form of construction of the apparatus and the power which is put into it. A coil such as has been described above, when the transformer is taking about twenty amperes at 110 volts and 7,200 alternations per minute, should give a discharge of sufficient volume to bring the filament of a 110-volt sixteen-candle-power lamp to a bright red when passed through it. We have seen as many as ten incandescent lamps brought nearly to candle-power when joined in series and the discharge from a high-frequency coil, capable of giving eight inches, passed through all of them. Observations taken on a wattmeter which measured the true power put into the apparatus apparently showed that the apparatus was taking less power than would be required with ordinary currents to light ten lamps to two-thirds candle-power, as they actually were lighted from the high-frequency discharge which was passed through them. To all appearances the filaments were brought to incandescence by true conduction currents. As far as the indications went, a considerably larger number than ten lamps could have been lighted in the same way and to the same brilliancy; as one lamp, when the current was passed through it alone, was lighted no more brilliantly than when passed through ten in series, and an air-gap, in series with the lamps over which the discharge passed, very slightly, if at all, diminished their glow. The explanation of this apparent paradox, that more energy was displayed in the lamps than was actually put into the apparatus, as measured by a wattmeter measuring true watts, can not be satisfactorily given by the writers. No opportunity has been presented to investigate the matter experimentally so as to reach a certain conclusion. We consider any explanation based upon theory as of little value and a study of the interesting phenomenon above described is suggested as being well worth the trouble. Any high-frequency

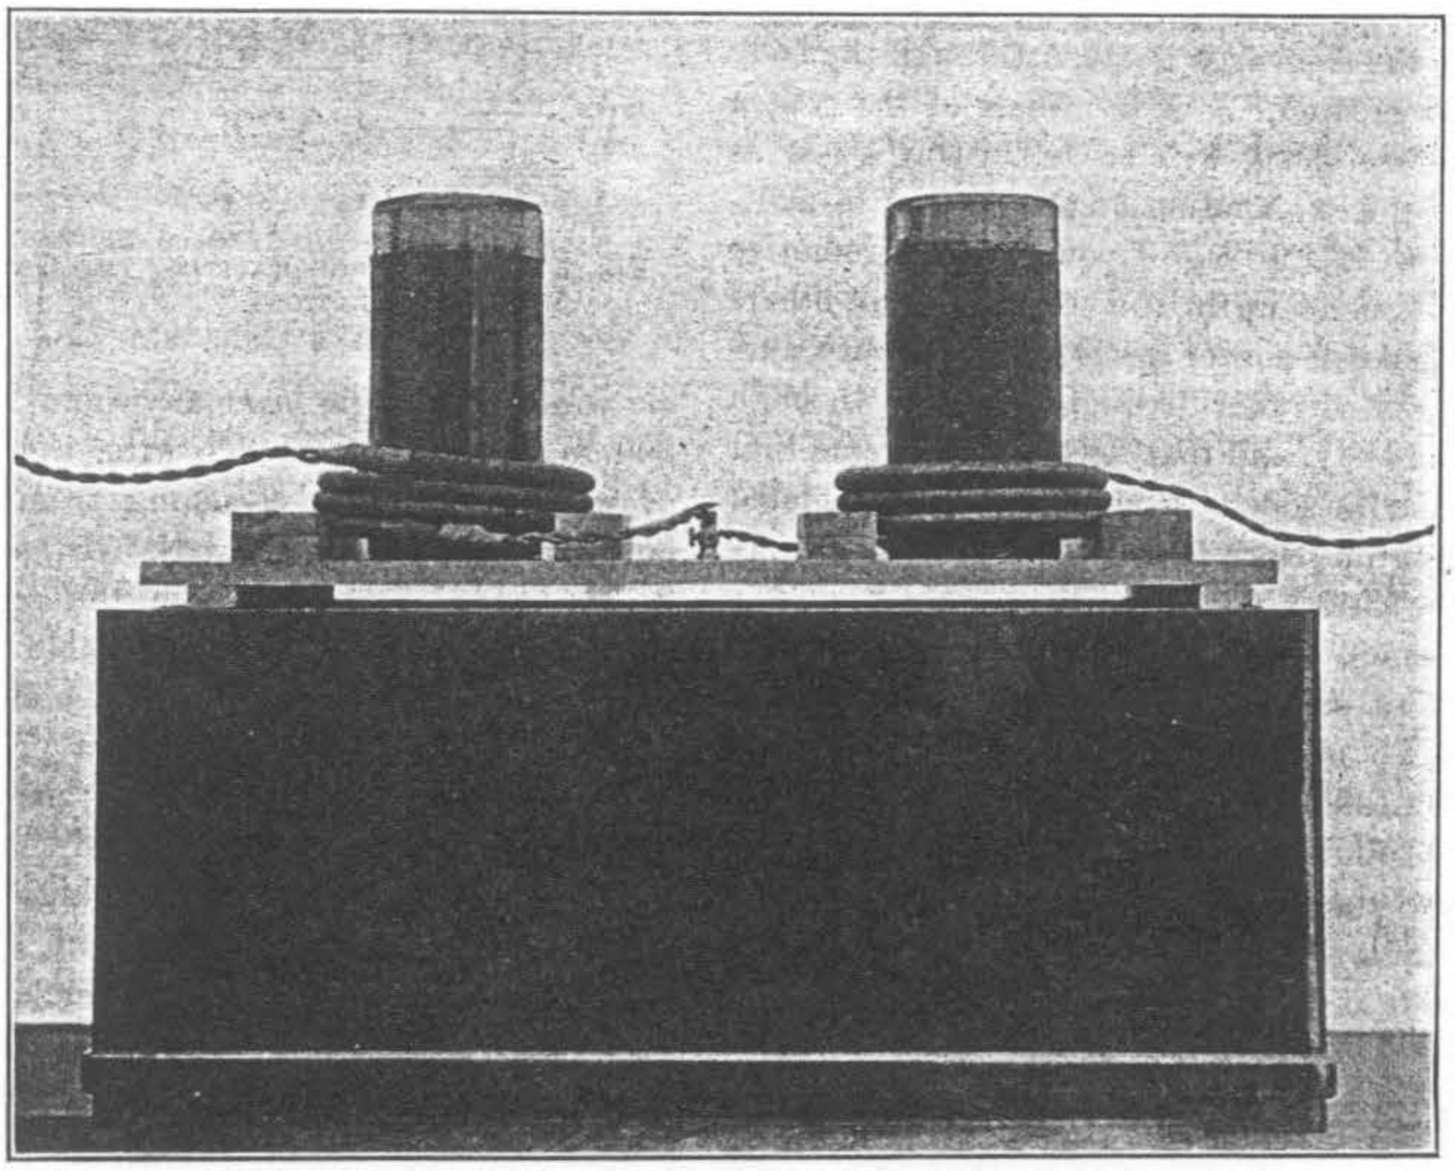

FIG. 6.—NO. 2 COIL—SUGGESTIONS FOR PRODUCING HIGH-FREQUENCY CURRENTS.

discharge which is not of sufficient volume to light up lamps, when passed directly through their filaments, may be considered poor as to what may easily be obtained by proper construction.

Many experiments were tried by the writers with the high-frequency apparatus shown in Figs. 5 and 6. None of the experiments was strictly new, having been described by Tesla and other writers, and only a brief mention will be made of some experiments which indicate strikingly the properties of high-frequency currents, which show phenomena totally unlike direct currents and those of moderate frequency. Thus, presenting a piece of metal held in the hand to one terminal of the high-frequency coil draws a discharge from the terminal into the body, even though the body be insulated by a stool with glass legs. Simple and common as is this observation to those familiar with high-frequency currents, it would be inexplicable to one who does not appreciate that electricity always flows in a closed circuit, and that the circuit, according to Maxwell's theory, is, for high-frequency currents, as perfectly closed through the dielectric medium as it is through a wire for ordinary currents. The experiment as described can be performed without any disagreeable sensations, but, contrary to the common notion, if the discharge is taken through the body by grasping both terminals of the coil, a severe shock will be felt. Our guess as to the explanation of this is that in addition to the high-frequency electromotive forces set up in the coil, there are others of much slower period which cause currents of lower frequency to pass through the body, and that it is these currents that give the shock. When the body is insulated and one terminal is touched, it is only the currents which have a very high frequency that can pass into the body and these produce little or no sensation.

To obtain from a high-frequency coil a most brilliant display of light, proceed as follows: take a large piece of plate glass and fasten a piece of tin-foil about as big as a dollar on each side of the glass near its centre. Connect to each piece of tin-foil a terminal of the coil. When the coil is in operation, even if it is a very large one, the discharge will not puncture the glass, but will spread out in fiery streamers on each side of the glass like the roots of a tree, covering a wide area and producing a most beautiful effect, especially when seen in the dark.

All kinds of vacuum tubes, including electric light bulbs, can be made to glow brightly by being held in the hand and approached to one terminal of the coil. Vacuum tubes will generally glow if suspended between two metal sheets which are connected to the terminals of the coil. Many other experiments along the same line, which attracted such lively attention when first exhibited in a striking manner by Tesla, can be performed with a coil constructed like those described above.

A very beautiful display of light and a high-frequency discharge of considerable length can very easily and inexpensively be obtained by constructing an air-insulated coil made as follows: Describe on the top of an old wooden table two concentric circles, the inner one about three feet in diameter and the outer one about four and one-half feet in diameter. On the circumference of each circle bore fifteen or twenty evenly spaced holes. In each hole insert a rod about three feet long, of hard, dry wood, glass or fibre. Around the upright rods of the inside circle wind in a single layer anywhere from 500 to 1,000 turns of fine wire, the coil of wire thus formed reaching from the bottom to the top of the rods. Bring the bottom terminal up through the centre of the coil, fastening it to a suitable support above the coil. Wind around the outside circle of upright rods, eight or ten turns of heavier wire, say No. 12; making the outside turns the primary and the inside turns the secondary of a high-frequency coil, the other parts of the high-frequency apparatus being the same as we have described above, a high-frequency discharge of a foot or more in length may be obtained. If the terminals of the secondary are separated, so that the discharge can not pass, the wire coils formed as above will appear, when viewed in a darkened room, like a huge, brilliantly glowing cylinder of purplish light. One of the writers once entertained a small audience of ladies and gentlemen for an hour and a half with a display of a large

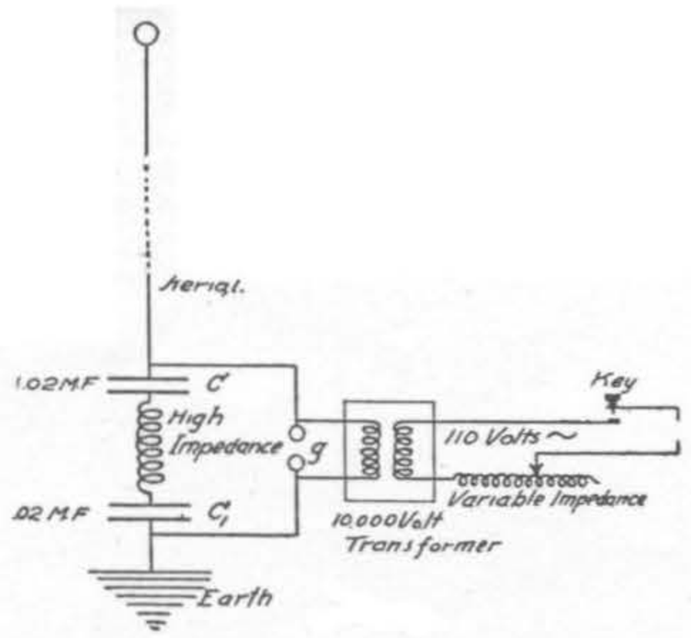

FIG. 7.—METHOD FOR EXCITING THE OSCILLATIONS.

variety of light effects obtained with a high-frequency apparatus, and we know of no more pleasing entertainment than can be furnished with properly selected experiments performed with a high-frequency apparatus of large power.

The high-frequency currents of low potential which pass through the primary circuit only may be made to yield in a simple manner many striking effects of induction and impedance. Thus an impressive but simple experiment is performed as follows: a single turn of heavy wire is made to complete the condenser circuit. Another single turn of heavy wire is connected near its ends by a suitable mounting upon which a small lamp socket is placed, containing a lamp of about six candle-power. The mounting of the lamp is so arranged that it can be used as a handle. When the condenser current is flowing through a single turn of wire and this is approached with the turn holding the small lamp, the latter will light up when the turns are at some little distance and can readily be made to give its full candle-power. One of Tesla's experiments is easily performed with great success as follows: a one-quarter-inch brass rod ten feet long is bent at its centre so as to form a narrow arch, the vertical sides of which are about ten inches apart. Suitable slides are made to work on these rods and upon these slides electric lamp sockets are placed. As we performed the experiment, a sixteen-candle-power lamp was placed in one socket near the bottom of the arch. Near the centre of the arch a ten-candle-power lamp was placed. Near the top an eight-candle-power lamp. When the current is taken from the condenser and passed through the arch, the phenomena of impedance are strikingly shown by these lamps. The lower lamp lights up nearly to full candle-power. The middle one remains dark, and the upper one, if care is not taken, will quickly burn out.

These simple experiments, and a great many others which space will not permit us to describe, can be performed by any one and the appliances for them can generally be made with very little trouble.

So many of these experiments come to the mind of one working with high-frequency currents, and go to show in a most convincing manner how influential are the effects of capacity, impedance and molecular bombardment, that it seems to us that the physical laboratory of any school or college is not complete unless supplied with apparatus for the production of high-frequency phenomena.

As the spectacular features of high-

frequency currents increase with the length and volume of the discharge which is obtained, it is of interest to many persons to strive to obtain the most powerful apparatus which can be built. The largest apparatus, for which the writers have specifications, gives a discharge of thirty-two inches.

It is probable, however, that an apparatus could be constructed which would give a discharge of considerably greater length and volume sufficient to bring sixteen-candle-power lamps to incandescence. The experience of the writers would indicate that the form of construction shown in diagrams 1 and 3 is that which is best adapted to obtaining the longest possible discharge lengths with greatest safety in insulation, and with apparatus constructed in the smallest compass. Whatever the length of discharge one wishes to obtain, the apparatus should be proportioned as above described. Roughly speaking, the length and diameter of each half of the secondary coil should be the same. For each inch of secondary winding of one-half of the secondary coil, two inches of discharge can be obtained. A good oil to use for the insulation is a clear thin paraffin oil, and its dielectric strength can be reckoned as at least ten times that of air for high-frequency potentials. As shown in a previous article by one of the writers, the dielectric strength of oil is greater for high-frequency potentials than for low-frequency potentials. If the above considerations hold beyond the range over which the writers have experimented, one ought to be able to obtain a discharge five feet in length with a coil, each half of which has a secondary winding about thirty inches high and about thirty inches in diameter at its base, and about twenty-two to twenty-four inches at its top. Of course, the greater the discharge length with a discharge having a given thickness, which one wishes to obtain, the greater must be the capacity of the transformer which charges the condenser. Our experiments indicated that the primary of the transformer required about one ampere at 110 volts pressure for each inch of high-frequency discharge, which had sufficient volume to light an incandescent lamp of sixteen candle-power. If great discharge lengths are sought, the condenser should be arranged to withstand a potential that will disrupt a parallel gap of at least one and one-half to two inches. The most feasible way to obtain a condenser of this strength and of sufficient capacity is to construct four condensers like the one described above, and join two pairs in series. It may here be remarked that to double the dielectric strength of a condenser and maintain its capacity unchanged, its volume must be increased four times. It is better to make several condensers and join them together in the combinations required for the capacity and dielectric strength sought, than to make one large condenser. In the former case, various capacities can be obtained for experimental purposes, and breakdowns are much more easily repaired.

The commercial uses of a powerful high-frequency coil are not very obvious at the present time. A coil, however, giving a six-inch discharge is very useful for the production of X-rays, chiefly where these are to be used for therapeutic purposes and where sharpness of definition is not essential. A coil of moderate power will excite a large tube to its fullest capacity, which will very brilliantly light fluorescent screens. It is possible that the physiological effects produced by charging the body of an insulated person from one terminal of a powerful coil may have certain beneficial effects.

Unquestionably, the best method of charging the aerial wire in wireless telegraphy experiments is by means of an oscillating discharge made with condensers and a transformer. One of the writers in April, 1902, made several experiments on the application of a transformer and condensers to exciting oscillations in the aerial of a wireless telegraph station. We can not enter into a full description of this much discussed subject, but for reference a diagram is here given of one method for exciting the oscillations, which was tried with great success. Consult Fig. 7, which is self-explanatory to those familiar with wireless telegraphy. The method shown in the diagram is only one of several that were successfully tried. The large impedance, which consisted of the secondary of a small induction coil, permitted the two condensers C and C to become charged from the transformer, but when the air-gap broke down a powerful surge of electricity was produced up and down the aerial and through the air-gap *g*, the resistance of which is greatly reduced by the heavy flow of current from the condensers and transformer. This was proved by the action on the coherer, the blowing of the fuses in the electric light circuits of a near-by building, as well as by the fact that sparks of considerable length could be drawn from the aerial a third way up its length into an insulated conductor, such as the blade of a shovel, which was held near it. In these experiments, the discharge across the gap would answer instantly to the most rapid tapping of the key, and the energy available was vastly in excess of what might be obtained from an induction coil.

In conclusion, we have to say that the phenomena of oscillating currents and high-frequency discharges are so complex, and the observations made so unexpected, that one must rely almost entirely upon experiment to learn what will happen each time that the conditions are slightly varied.

Tesla's Split Phase Motor Patent Decision.

Judge Hazel, of the United States Circuit Court of the Western District of New York, has handed down an opinion sustaining the two Tesla fundamental patents (Nos. 511,559 and 511,569), covering the split-phase motor. The suit was instituted by the owners of the patents against the manufacturer of a wattmeter, and the court held that the wattmeter infringed the patents for the reason that it depended for its action on two currents differing in phase, derived from a single supply circuit.

The patents involved were the same that figured in the Catskill case, in which suit they were sustained by the Circuit Court, but declared invalid upon appeal. This reversal was on the grounds that the publication of a magazine article on April 22, 1888, by Prof. Galileo Ferraris fully described and disclosed the system covered by the patents. This publication was held to be prior to the date of the invention in suit and constituted an anticipation.

Judge Hazel, in his opinion, disagrees very materially with Judge Townsend, who wrote the opinion on appeal, declaring the patents invalid. The conflict arises from the different weight which the two judges gave to the testimony of the several leading witnesses, this testimony being held by Judge Townsend to be inconclusive, and by Judge Hazel to establish clearly that Tesla conceived the invention prior to the publication of the Ferraris article. Judge Hazel considers that, according to the testimony, Tesla conceived his split-phase invention in his laboratory at 89 Liberty Street, New York, and completed the same in the month of September, 1887; and that he made the disclosure thereof to others during the fall of 1887, especially to Mr. Brown and Mr. Nellis, and subsequently in the month of April prior to the Ferraris publication to his solicitor, Mr. Page.

PATENT LITIGATION.

Tesla Split-phase Motor.

The suit of the Westinghouse Electric and Manufacturing Company against the Mutual Life Insurance Company of New York and H. C. Mandeville, brought to recover for alleged infringement by the defendants of Tesla patents, Nos. 511,559 and 511,560, has been decided in favor of the complainant. The infringement complained of was brought about by the use by the defendants of an alternating split-phase motor in a recording wattmeter, the infringing apparatus used being the Gutman meter. Judge Hazel, in his opinion, filed in the United States Circuit Court for the Western District of New York, on final hearing, says that the defense is "want of patentability, non-infringement and anticipation."

The first claim of patent No. 511,559 relates broadly to the method and extent of retardation of the phase of the current. The second claim refers specifically to the method of accomplishing in the electric currents a difference of phase. The claims of patent No. 511,560 refer particularly to the apparatus for effecting the object of the process of patent 511,559, and specify the devices constituting the split-phase motor with a single circuit. The construction adopted by the court is as follows:

"By the method and means therein described Tesla dispensed with one of the line circuits, and was able to run the motor by means of alternating currents from a single original source. This was accomplished by means which retarded the phases of the current in all circuits, or so varied the relative resistance of the motor circuits as to maintain the necessary difference in phase in the currents. Such utilization of a single original source by thus splitting a single current into two currents was an improvement of great practical value."

Of the contention that the patents were invalid because anticipated by the admitted publications of Prof. Galileo Ferraris on April 22, 1888, in Turin, Italy, Judge Hazel says: "Upon careful consideration of the proofs I have arrived at the conclusion that the actual date of the Tesla inventions is prior to this publication and that the patents were not void for anticipation. According to the evidence, Tesla conceived his invention in his laboratory, No. 89 Liberty Street, New York city, and completed the same in the month of September, 1887. He made disclosure thereof to others during the fall of 1887."

Judge Hazel concludes with the statement that the defendant has failed to establish any of the grounds upon which complainant's right to sue for infringement depends, and the complainant is therefore entitled to a decree in the usual form, with costs and disbursements.

The New York Times March 27, 1904

CLOUDBORN ELECTRIC WAVELETS TO ENCIRCLE THE GLOBE

This is Nicola Tesla's Latest Dream, and the Long Island Hamlet of Wardenclyffe Marvels Thereat.

TO gather in the latent electricity from the clouds and with the globe itself as a medium of transmission to convey telegraphic messages, power for commercial purposes, or even the sound of the human voice to the utmost confines of the earth is the latest dream of Nikola Tesla.

In an article which appeared recently in The Electrical World Mr. Tesla explains the theories on which the world telegraphy system is founded and what he expects to accomplish by it. His plans involve the establishment of stations for the transmission of messages and power, "preferably near important centres of civilization." Oddly enough, what Mr. Tesla proudly designates as the first of his commercial "world telegraphy" stations has been established at Wardenclyffe, L. I., which is not in any sense an important "centre of civilization," but a place described by train hands of the Long Island Railroad as a way station where "a passenger alights occasionally."

The transmitting station is an octagonal tower, pyramidal in shape, and some 180 feet in height. It consists of huge wooden stilts, heavily braced and reinforced, and surmounted by a cupola of interlaced steel wires, bent so as to form an arc. In the cupola there is a wooden platform occupying its entire width.

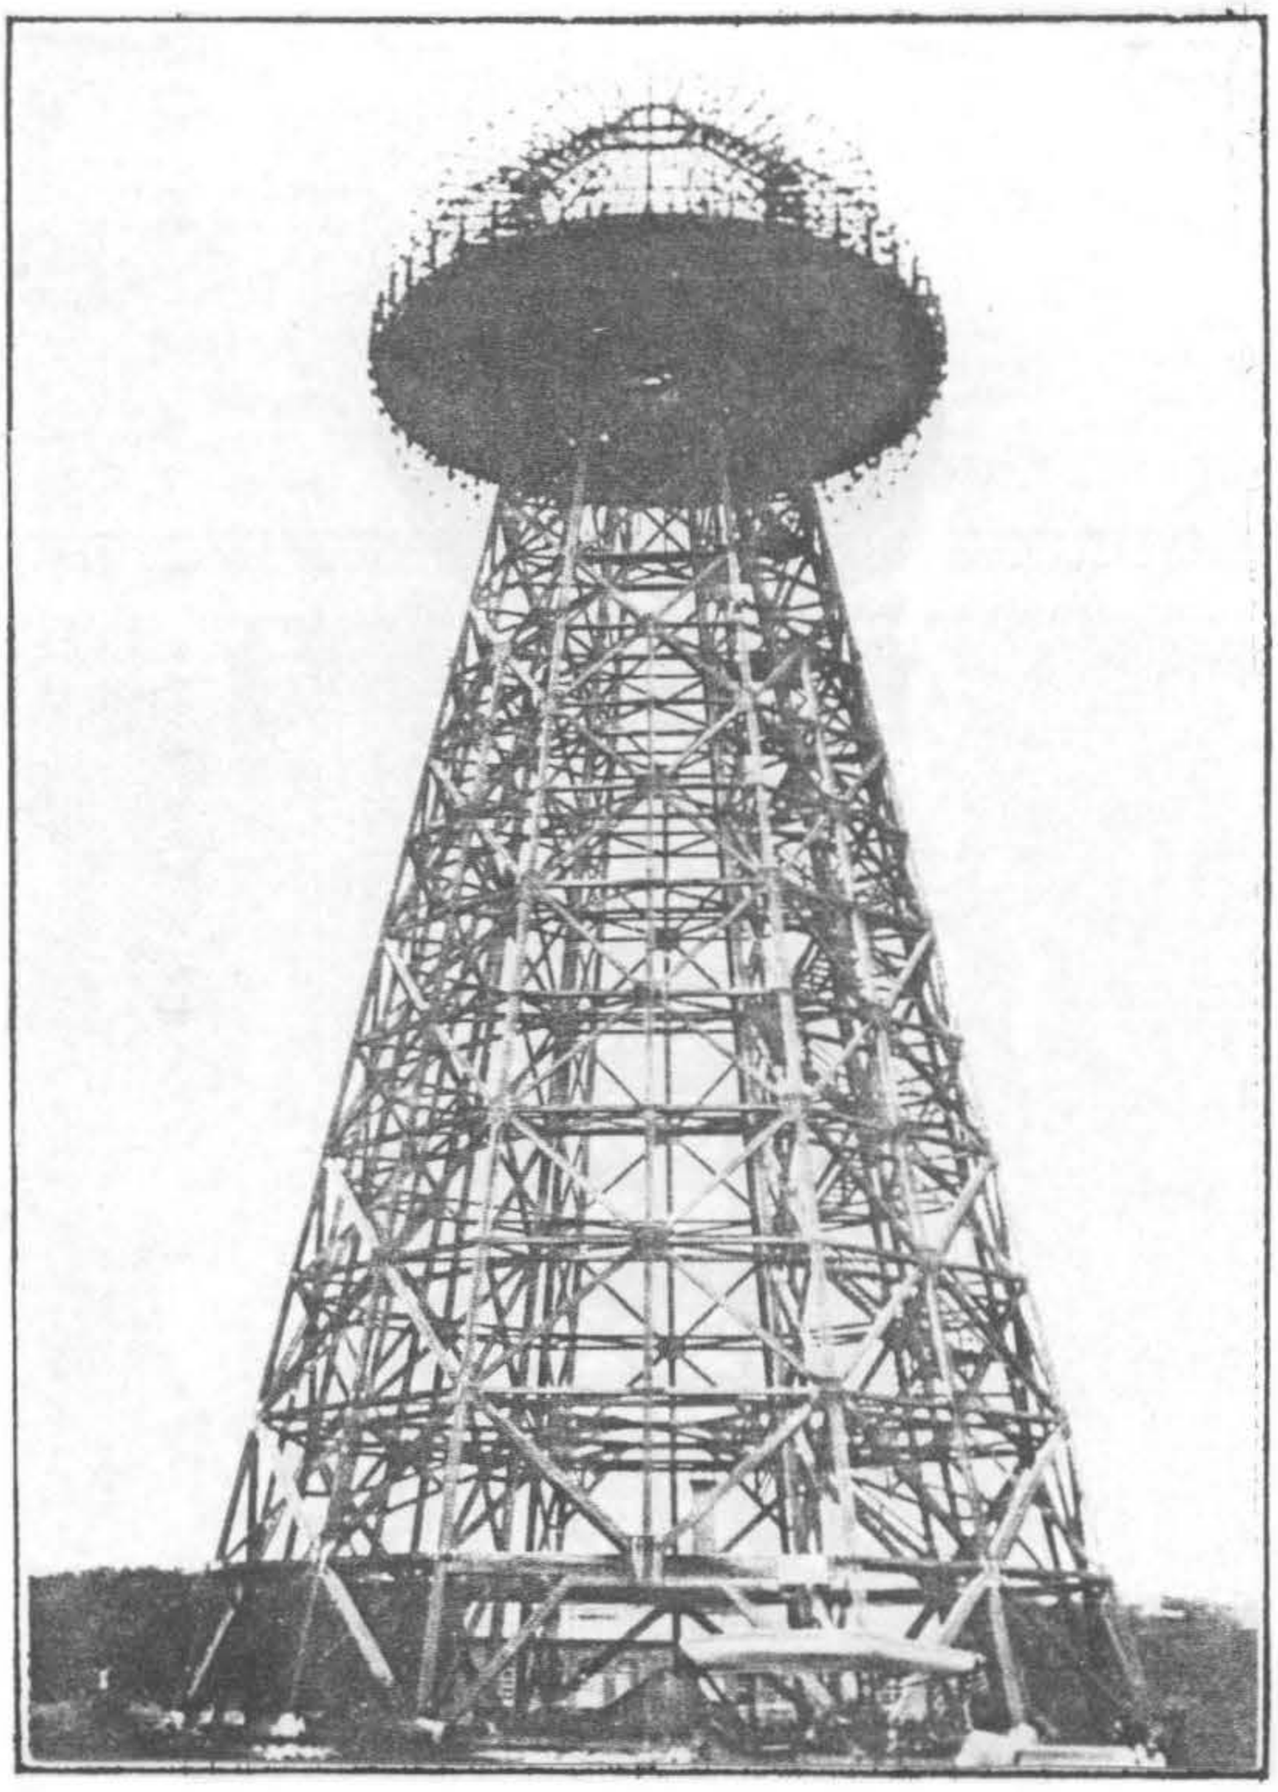
Mr. Tesla began work on his transmitting station about eighteen months ago. When he first came there, and it was understood that J. Pierpont Morgan had become interested in his odd enterprise and furnished him with financial assistance, a thrill of vague expectancy ran through the little settlement. The Wardenclyffe Land Company, which owns practically all the available ground in the vicinity, gave the inventor a free grant of some 175 acres of fine land, and then settled down to wait for the day when Wardenclyffe would become the centre of the universe.

Some of the farmers who come to Wardenclyffe to send their products to this city look at Mr. Tesla's tower, which is situated directly opposite the railroad station, and shake their heads sadly. They are inclined to take a skeptical view regarding the feasibility of the wireless "world telegraphy" idea, but yet Tesla's transmitting tower as it stands in lonely grandeur and boldly silhouetted against the sky on a wide clearing on the concession is a source of great satisfaction and of some mystification to them all.

"It is a mighty fine tower, said one good farmer to a visitor last week. "The breeze up there is something grand of a Summer evening, and you can see the Sound and all the steamers that go by. We are tired, though, trying to figure out why he put it here instead of at Coney Island."

While the tower itself is very "stagey" and picturesque, it is the wonders that are supposed to be hidden in the earth underneath it that excite the curiosity of the population in the little settlement. In the centre of the wide concrete platform which serves as a base for the structure there is a wooden affair very much like the companionway on an ocean steamer. The tower and the inclosure in which it has been built are being carefully guarded these days, and no one except Mr. Tesla's own men is allowed to approach it. Only they have been allowed as much as the briefest peep down the companionway.

Mr. Scherff, the private secretary of the inventor, told an inquirer that the companionway led to a small drainage passage built for the purpose of keeping the ground about the tower dry. But such of the villagers as saw the tower constructed tell a different story



They declare that it leads to a well-like excavation as deep as the tower is high, with walls of masonwork and a circular stairway leading to the bottom. From there, they say, tunnels have been built in all directions, until the entire ground below the little plain on which the tower is raised has been honeycombed with subterranean passages.

They tell with awe how Mr. Tesla, on his weekly visits to Wardenclyffe, spends as much time in the underground passages as he does on the tower or in the handsome laboratory and workshop erected beside it, and where the power plant for the world telegraph has been installed.

No instruments have been installed as yet in the transmitter, nor has Mr. Tesla vouchsafed any description of what they will be like. But in his article he announces that he will transmit from the tower an electric wave of a total maximum activity of ten million horse power. This, he says, will be possible with a plant of but 100 horse power by the use of a magnifying transmitter of his own invention and certain artifices which he promises to make known in due course.

What he expects to accomplish is summed up in the closing paragraph as follows:

"When the great truth, accidentally revealed and experimentally confirmed, is fully recognized, that this planet, with all its appalling immensity, is to electric currents virtually no more than a small metal ball and that by virtue of this fact many possibilities, each baffling imagination and of incalculable consequence, are rendered absolutely sure of accomplishment; when the first plant is inaugurated and it is shown that a telegraphic message, almost as secret and non-interferable as a thought, can be transmitted to any terrestrial distance, the sound of the human voice, with all its intonations and inflections faithfully and instantly reproduced at any other point of the globe, the energy of a waterfall made available for supplying light, heat, or motive power, anywhere—on sea, or land, or high in the air—humanity will be like an antheap stirred up with a stick. See the excitement coming!"

TESLA'S MYSTERIOUS TOWER

With the aid of this structure the inventor proposes to operate a system of wireless telegraphy covering all the earth.

[409.]—**Tesla Oil Transformer.**—To Mr. Bottone.—I have made several of these, but none with the primary *outside* the secondary. But I do not think that the reverse position you propose would greatly influence the result, except perhaps as it may necessitate a rather longer length of primary wire. The gauge of your primary is very large, so I presume you propose using a very heavy current, say, 30 or 40 amps., as a minimum. I have never tried *bare* wire for the primary, but with oil insulation, provided the spirals can be kept accurately spaced, I see no reason why it should not do as well as covered wire. The secondary *must* be most heavily insulated (guttapercha, about $\frac{3}{32}$in. diameter, seems to give the best results). For the mode of construction see "Electrical Transmitters for Amateurs," p. 109, 7th edition. The difference in the spark, provided the *length* of secondary be the same, would be that the stouter wire would give a rather fatter spark. Not much; because, compared with the enormous voltage in the secondary, the difference of resistance would be but very trifling.

S. Bottone.

Tesla Split-Phase Motor Patent Decision.

Judge Kohlsaat on Saturday of last week handed down a d in a case involving the Tesla split-phase motor patent brought before the U. S. Circuit Court for the Northern District of Illinois, which decision upholds the Tesla patent and grants an injunction against the use of the split-phase principle in a wattmeter made by the defendants in the action. The opinion cites the opinions of Judges Archbold, Hazel, Townsend and Lacombe sustaining the patent, and the opinion of the Court of Appeals reversing the Lacombe decision, which latter ruling was followed by Judge Colt in another case. All of the above cases have been reported in these columns.

Judge Kohlsaat says that the decision of Judge Lacombe was reversed largely upon the ground that it did not appear from the record that Tesla's invention was not anticipated or described in a paper read by the late Prof. Ferraris before the Royal Acadmy of Sciences, of Turin, Italy, on March 18, 1888, and published, in part, in an electrical journal issued at Milan on April 22, 1888. He holds, however, that in the later cases—those decided by Judges Archbold and Hazel—the records, together with certain original proofs offered in the present case, establish that Tesla's invention in suit antedated the Ferraris article, was original with Tesla, and that his patents are valid.

The Colorado Springs Gazette April 6, 1904

TESLA IS SUED

Is Asked to Pay for Electricity Furnished Experimental Station He Abandoned.

Nicola Tesla, the famous electrical expert, whose experiment station on Knob hill has furnished material for queries on the part of visitors here during the past few years, is the defendant in a suit instituted in the county court yesterday by the Colorado Springs Electric company. The suit is brought to secure judgment for $180, said to be due for electrical energy furnished Tesla from June 1, 1903 to March 31, 1904. Tesla himself has not been in Colorado Springs for three years and the sheriff's office is trying to locate him for the service of the papers.

Tesla erected his experiment station for the purpose of perfecting his apparatus for the transmission of telegraphic messages without wires. Recently Tesla was sent a bill by the city for water furnished the station. In his novel reply he said that inasmuch as he had graced this city with his presence and had erected an experimental station here, he considered that the city should donate all the water used at the station.

Tesla Sued.

Nicola Tesla, the famous electrical expert, whose experiment station on Knob Hill has furnished material for queries on the part of visitors here during the past few years, is the defendent in a suit instituted in the county court yesterday by the Colorado Springs Electric company. The suit is brought to secure judgment for $180, said to be due for electrical energy furnished Tesla from June 1, 1903, to March 31, 1904. Tesla himself has not been in Colorado Springs for three years and the sheriff's office is trying to locate him for the service of the papers.

Tesla erected his experiment station for the purpose of perfecting his apparatus for the transmission of telegraphic messages without wires. Recently Tesla was sent a bill by the city for water furnished the station. In his novel reply he said that inasmuch as he had graced this city with his presence and had erected an experimental station here, he considered that the city should donate all the water used at the station.—The Gazette.

Wednesday Tesla's experiment station on Knob Hill was attached and will be sold under the hammer in five days if the $180 due the Electric company is not forthcoming.

Tesla Split-phase Patents.

In the action brought by the Westinghouse Electric and Manufacturing Company against the Electric Appliance Company of Chicago to restrain that company from selling or manufacturing the Gutmann wattmeter, Judge Kohlsaat of the United States Circuit Court in Chicago handed down the following decision on March 26th, sustaining the Tesla patents Nos. 511,559 and 511,560, on the rotating-field split-phase system, and granting the injunction asked for:

"This case comes now on to be heard upon complainant's motion for an injunction pendente lite restraining defendant from infringing letters patent Nos. 511,559 and 511,560. The inventions relate to the operation of rotating-field motors upon a single alternating-current circuit, under what is known as the Tesla split-phase system, applied in the present case to the operation of electric motors. The former patent covers the method of operating the motors, while the latter covers the means for so doing. The inventions may be said to consist in splitting the current, at the motor, into two or more branches, constituting the independent circuits of the motor, and producing by artificial means the difference of phase necessary to operate the motor. The drawings of the patents seem to call for an armature in the form of a cylinder.

"The defendant's armature consists of a disk. The specification and claims, however, of the patents in suit are not limited to details of form, but call broadly for 'an armature within the influence' of the energizing circuits. I am of the opinion that defendant's device is fairly embraced within the terms of the patents in suit. Both are operated under the principles of Tesla's patent of May 1, 1888, the invention of which was the production, by means of a series of stationary magnet poles, energized by alternating currents of different phase, of an effect upon an armature, mounted within the influence of such poles, similar to that which would be produced upon the same armature by rotating around it bodily the pole or poles of a physical magnet. The equivalency of the two is shown in Gutmann patent No. 614,225, under which defendant's device is manufactured. The difference in the location and application of the magnetic influence is equalized and compensated by a corresponding difference in the angles of the slots in the cylinder or disk. The principle of the rotary impulse and progression is the same. The question is satisfactorily settled for the purpose of this motion by the respective decisions in the suits brought by complainant herein v. Roberts, decided by Judge Archbald of the Eastern District of Pennsylvania, September 10, 1903, and same v. Mutual Life Insurance Company et al., decided by Judge Hazel of the Western District of New York, February 4, 1904.

"I deem the question of infringement duly established. From the record it appears that the validity of the patents in suit is assailed principally upon the Bailey and Ferraris publication set out. The former was practically eliminated from this case by the decision of Judge Townsend of the Second Circuit in the original suit upon Tesla's fundamental patents Nos. 381,968, 382,279 and 382,280, entitled Westinghouse Electric and Manufacturing Company v. New England Granite Company, 103 Fed. Rep., 95, which ruling was affirmed on appeal 110 Fed. Rep., 753, and again by Judge Archbald in the Roberts case (supra.). In the case of this complainant v. the Catskill Illuminating and Power Company, 121 Fed. Rep., 631, the Court of Appeals for the Second Circuit reversed the decision of Judge Lacombe, 110 Fed. Rep., 377, largely upon the ground that it did not appear from the record that Tesla's said inventions were not anticipated or described in the paper read by Professor Ferraris before the Royal Academy of Sciences, of Turin, Italy, on March 18, 1888, and published, in part, in an electrical journal issued at Milan on April 22, 1888. This ruling was followed by Judge Colt of the First Circuit in the case of complainants herein v. Stanley Instrument Company, not yet published. In the cases of Roberts and Mutual Life Insurance Company of New York (supra.), as herein, this difficulty was overcome. The records in those cases, together with certain original proofs herein, corroborative thereof, are now before the court, from which I am satisfied that Tesla's inventions in suit antedated the Ferraris article, and were original with him, and that the said patents are valid.

"It therefore becomes unnecessary to pass upon the other questions raised by complainant.

"The patents being found valid for the purposes of this motion, and also infringed, it follows that the preliminary injunction should be granted. Complainant's counsel may prepare an order in compliance herewith."

OUR GREAT PATENT OFFICE.

Nikola Tesla Discusses Its Workings and Calls for More Liberal Appropriations.

TO THE EDITOR OF THE SUN—*Sir:* It is to be regretted that statements discrediting the Patent Office should be given publicity, all the more as there is scarcely another institution reflecting such honor on the United States. Considering the vast amount and exquisite character of their work, the performance of the officials is really remarkable. In long personal experience I have found the examinations to be far more satisfactory than I would have ever thought possible. Many times I have noted with astonishment the thorough grasp of ideas, the keenness of the criticisms and the exhaustiveness of the search for anticipations, and invariably I have obtained valuable knowledge through the references cited and suggestions made.

The Patent Office is so vital to the interests of this country that any expressions capable of creating a doubt in the minds of people as to the faithful performance of duties and competency of its organs must be deemed unfortunate. Almost all the technical arts, industries and undertakings are more or less founded on patent protection, and if the belief should gain ground that the men called upon to render important decisions are incapable, and that the Commissioner in charge is a Khan, or Mogul, or Pooh Bah, running the office to suit his whims, public confidence in the value of these properties might be destroyed.

As a matter of fact, while it is true that examiners can never keep quite abreast with inventors, they are men well educated and trained, recruited from colleges. In addition to acquiring the indispensable special knowledge, they must pass an examination in physics, chemistry, quantitative and qualitative analysis, mathematics, including calculus, mechanical drawing and foreign languages. Surely such men should be able to understand an idea and to pass intelligently on the general merits of the documentary evidences submitted. Serious dissatisfaction, then, is not likely to arise from an examiner's deficient knowledge or lack of comprehension. Nor is it apt to come from an inherent defect of adopted procedures, although some of these might be omitted to advantage. For example, the suggestion of claims by the examiner in a case of conflicting applications is, in my opinion, always in favor of the inventor possessed of better knowledge and stronger imagination. The introduction of greater rigidity in the withdrawal and amendment of specifications might also be helpful. But, after all, what difference does it make how the original documents are modified? The successive changes are all recorded and can be examined at any time. If new matter is injected in an amended application it will not be permitted to remain, and, ultimately, the testimony in the interference will bring out the exact facts which will settle the question of priority. The advantages which might be secured by such or similar changes would be slight. But great improvements can be made in another direction.

Of late years the demand on certain departments has been increasing so fast that more expeditious methods had to be adopted; and this has naturally detracted from the quality of the work. The remedy, however, is simple and should be at once applied. What the Patent Office needs is a liberal appropriation.

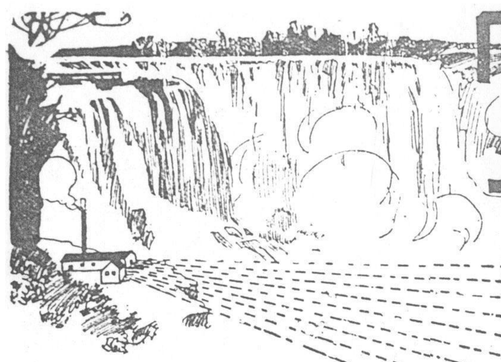
One of the greatest problems confronting the world is to devise methods and means for protecting intellectual property. As we develop, this need asserts itself more and more. The ultimate aim should be to arrive at laws and regulations at least as precise as those which define the ownership of tangible things. A new principle is still to be discovered which will make this possible. Perhaps in the distant future, photographic records of the retina of the eye may furnish a foundation for a new and more perfect system of protection and just valuation of the creations of the mind. As far as I am able to understand the working of the human mechanism, such records offer the only chance of doing away with the present imperfect ideas of possession and use of crude equivalents. But let us bear in mind that for the time being the United States Patent Office is the farthest advance toward that ultimate aim. Taking this broader view of the institution we shall better appreciate its immense influence on the welfare and morals of the country.

So important an establishment should be provided for with the greatest liberality. This is by no means the case at present. All the departments are cramped to the utmost, and the salaries of the officials are ignominiously small. An examiner starts with $1,200 a year as fourth assistant, and may manage to get up to $1,800 as first assistant. The examiner-in-chief, whose decisions are so far-reaching, draws the noble salary of $2,500 a year. By the time he has attained this exalted position he realizes that he can earn four times as much elsewhere and he sends in his resignation. From the official replies I notice that in Division 16 no less than four chief examiners—Bissing, Rice, Winter and Dean—have left their posts in less than six years. That was a great loss to the Patent Office. Nothing but generous provision will do away with this evil. I should say that the salaries of the examiners should be at least doubled and their number increased, so as to induce able men to remain in office and permit the employment of specialists. A monumental building should be erected affording ample space, well lighted and ventilated, and provided with the most perfect facilities for the making of records and experimental demonstration of ideas.

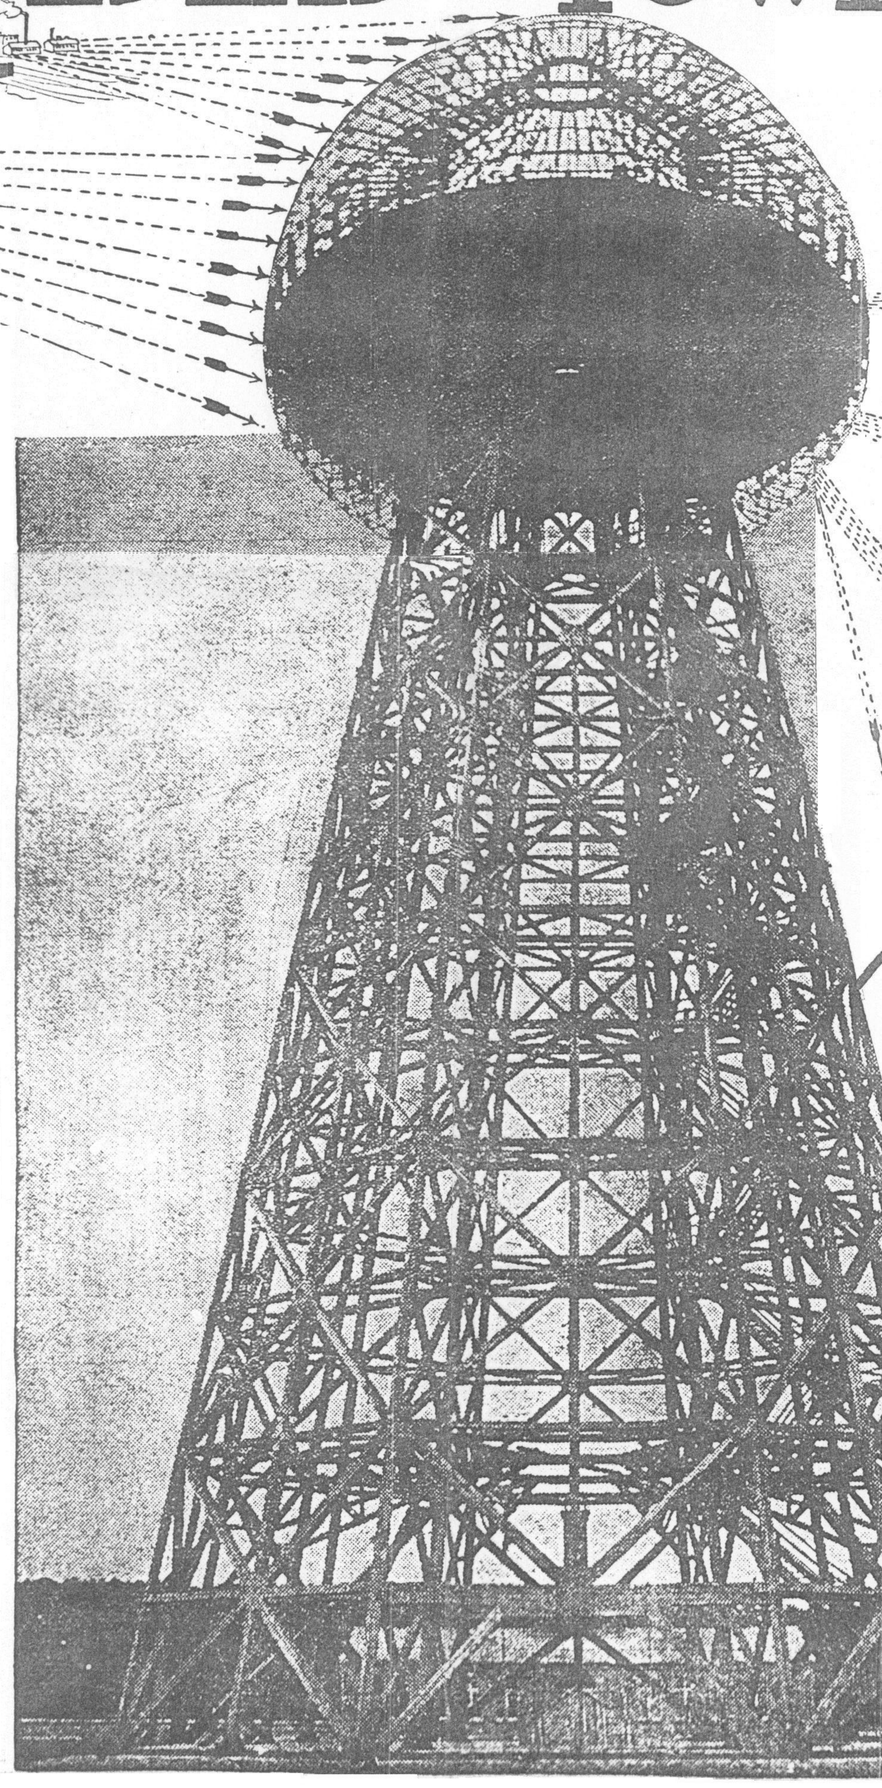
For such purposes no expenditure could be too large. In a time when millions are allowed by our Government for what in but a few years must inevitably be turned into scrap iron and lost to the world, one of the greatest institutions in existence, of which even now the United States has every reason to be proud, should not be forgotten.

NEW YORK, May 18. NIKOLA TESLA.

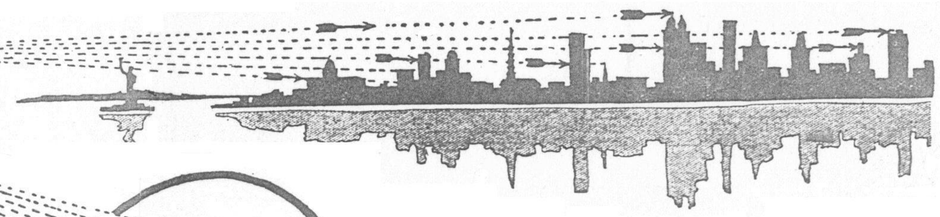
Tesla on the Patent Office.



The New York *Sun* of Wednesday contained a letter from Mr. Nikola Tesla in which, referring apparently to recent publications concerning difficulties between Edison and the Patent Office, he takes up the cudgels for the office and is particularly complimentary in references to its technical staff. In a long personal experience he said he has found the examiners to be far more satisfactory than he had thought possible, and many times he has noted with astonishment the thorough grasp of ideas, the keenness of the criticisms and the exhaustiveness of the search for anticipations, while invariably he has obtained valuable information through the references cited and the suggestions made. He considers any criticism capable of creating a doubt in the minds of people as to the faithful performance of duties and competency of its staff must be deemed unfortunate, since such doubt may destroy confidence in the value of patent property. Mr. Tesla advocates more liberal appropriations and more suitable quarters for the Patent Office, and refers to the fact that owing to low salaries difficulty is found in retaining the services of competent men.



While examiners, he says, can never keep quite abreast with inventors, they are men well educated and trained, recruited from colleges, and to obtain appointment have to pass a severe examination covering the several branches of applied and cognate sciences. Serious dissatisfaction then is not likely to arise from the examiners' insufficient knowledge or lack of comprehension, nor is it apt to come from an inherent defect of adopted procedures, although some of these might be omitted to advantage. For example, the suggestion of claims by the examiner in a case of conflicting applications is, in my opinion, always in favor of the inventor possessed of better knowledge and stronger imagination. The introduction of greater rigidity in the withdrawal and amendment of specifications might also be helpful. But, after all, what difference does it make how the original documents are modified? The successive changes are all recorded and can be examined at any time. If new matter is injected in an amended application it will not be permitted to remain, and, ultimately, the testimony in the interference will bring out the exact facts which will settle the question of priority. The advantages which might be secured by such or similar changes would be slight. Of late years the demand on certain departments has been increasing so fast that more expeditious methods had to be adopted; and this has naturally detracted from the quality of the work. The remedy for this is a liberal appropriation.



Mr. Tesla considers that one of the greatest problems confronting the world is to devise methods and means for protecting intellectual property. "As we develop, this need asserts itself more and more. The ultimate aim should be to arrive at laws and regulations at least as precise as those which define the ownership of tangible things. A new principle is still to be discovered which will make this possible. Perhaps in the distant future photographic records of the retina of the eye may furnish a foundation for a new and more perfect system of protection and just valuation of the creations of the mind. As far as I am able to understand the working of the human mechanism, such records offer the only chance of doing away with the present imperfect ideas of possession and use of crude equivalents. But let us bear in mind that for the time being the United States Patent Office is the farthest advance toward that ultimate aim. Taking this broader view of the institution we shall better appreciate its immense influence on the welfare and morals of the country."

TESLA'S TOWER

Amazing Scheme of the Great Inventor to Draw Millions of Volts of Electricity Through the Air From Niagara Falls and Then Feed It Out to Cities, Factories and Private Houses from the Tops of the Towers WITHOUT WIRES.

(Photo from the Electrical World and Engineer.)

Tesla's Wireless Transmitting Tower, 185 feet high, at Wardenclyffe, N. Y., from which the city of New York will be fed with electricity and by means of which the camperout, the yachtsman and Summer resort visitor will be able to communicate instantly with friends at home.

AN enormous mushroom-shaped tower, a photograph of which is reproduced on this page, has just been completed at Wardenclyffe, Long Island, N. Y., by Nikola Tesla, the distinguished electric inventor. From this tower Mr. Tesla is now preparing to put into operation the most daring and amazing scheme ever conceived in the development of wireless telegraphy.

For over four years Mr. Tesla has been hard at work almost day and night experimenting and endeavoring to make his marvellous theory practicable. From time to time during that period he has intimated vaguely at the immensity of his plan, and the equally tremendous results that would follow its introduction, and now, at last, he has announced his preparedness to put his theories to their first practical test.

Briefly explained, Mr. Tesla's assurances of what we may surely expect within the next year or so are as follows:

A perfect system of world-wide wireless telegraphy through which widely separated friends will be able to converse instantaneously and without the slightest danger that their wireless conversations will be overheard by a third person.

Little instruments about the size and shape of a watch, to be carried in the vest pocket and which will record market quotations, races and important news features in very much the same manner as the familiar "stock ticker" does at present. These vest pocket newsgatherers will enable the wearer to tell at a glance the condition of the stock market, etc.; even though he be thirty miles out at sea or as far distant inland from the nearest newspaper, "ticker," telephone or telegraph office.

Another little watch-like instrument, with a dial face by means of which the wearer can transmit and receive wireless messages to and from friends many miles away, watches of both sender and receiver being keyed to a certain pitch to prevent their communications from going astray or falling into the watches of disinterested third persons.

Wireless Trains and Trolleys.

A ceaseless day and night service of millions upon millions of volts of electricity from the Canadian Niagara Power Company's electric power plants at Niagara Falls to the Wardenclyffe tower, the electric power being forwarded from there by Tesla's wireless system to New York City for the purpose of illuminating the entire metropolis, running elevated and subway trains and street cars, operating elevators, automobiles, trucks and ferryboats, furnishing heat and even winding up clocks and making them keep perfect time by a system of half-hourly regulation.

The erection of Tesla towers similar to the one now at Wardenclyffe, at convenient places everywhere for the purpose of distributing wireless telegraphy to be used for illumination, power and heat. Only such towers as are erected within a given distance from Niagara Falls will be supplied from the power plants there with electricity. Each other tower will derive its own power from a generating plant erected alongside or between the main uprights, and each will distribute about ten thousand horse-power of wireless electricity under a tension of one hundred million volts. Mr. Tesla declares that he is able to produce and handle that much with perfect safety from one tower. Each tower will be capable of transmitting heat, power and light to cities, factories and private houses within a radius of thirty miles or more. Eventually Mr. Tesla proposes the extension of this tower system until practically the whole North American continent is dotted over with them, spaced about sixty miles apart, so that practically every inch of ground is covered by the new wireless service.

The woodsman, yachtsman or Summer resort visitor, wherever he or she may be can be communicated with instantly through the medium of one of the little watch tickers. The point of a parasol held aloft a mast or short pole as the case may be, will ensure the complete "picking up" of the wireless message after the watch has ticked off the first signal in the pocket.

In short, as Mr. Tesla has frankly admitted the possibilities of his amazing engine are simply boundless. He has not been able to realise to what extent it may be developed in the future.

The Wardenclyffe tower is 185 feet high from the ground to the top of the cupola. The smallest dimension across the base of uprights is 97 feet. The height to ledge of cupola is 153 feet, while the cupola itself is 65 feet in diameter. The tower has eight sides, with a staircase and lift for reaching the cupola platform. It is there that the wireless vibrations are received and shot out again in the voltage desired to given points scattered over a very wide radius.

Newspaper Printed in Vest Pocket.

"Much has already been done toward making my system commercially available in the transmission of energy in small amounts for specific purposes as well as on an industrial scale," said Mr. Tesla. "The results attained by me have made my scheme of intelligence transmission easily realizable. It constitutes I believe, in its principle of operation, means employed and capacities of application, a radical and fruitful departure from what has been done heretofore. I have no doubt that it will prove very efficient in enlightening the masses, particularly in still uncivilized countries and less accessible regions, and that it will add materially to general safety, comfort and convenience, and maintenance of peaceful relations. It involves the employment of a number of plants, all of which are capable of transmitting individualized signals to the uttermost confines of the earth. Each of them will be preferably located near some important centre of civilization, and the news it receives through any channel will be flashed to all points of the globe. A cheap and simple device, which might be carried in one's pocket, will accurately record the world's news or such special messages as may be intended for it. Thus the entire earth will be converted into a huge brain as it were, capable of response in every one of its parts. Since a single plant of but one hundred horse-power can operate hundreds of millions of instruments the system will have a virtually infinite working capacity, and it must needs immensely facilitate and cheapen transmission of intelligence.

"The first of these central plants is already completed. The best design of which I knew has been adopted, and the transmitter will emit a wave complex of a total maximum activity of 10,000,000 horse power, one per cent of which is amply sufficient to 'girdle the globe.' This enormous rate of energy delivery, approximately twice that of the combined falls of Niagara, is obtainable only by the use of certain artifices.

"For a large part of the work which I have done so far I am indebted to the noble generosity of Mr. J. Pierpont Morgan, which was all the more welcome and stimulating as it was extended at a time when those who have since promised most were the greatest of doubters.

Wireless Clocks and Light.

"Meanwhile, the transmission of energy on an industrial scale is not being neglected. The Canadian Niagara Power Company has offered me a splendid inducement. In this first power plant, which I have erected at Wardenclyffe, I propose to distribute 10,000 horse-power under a tension of 100,000,000 volts, which I am now able to produce and handle with safety.

"One of the chief uses will be the illumination of residences. It takes very little power to light a dwelling with vacuum tubes operated by high-frequency currents, and in each instance a terminal a little above the roof will be sufficient. Another valuable application will be the driving of clocks and other such apparatus. These clocks will be exceedingly simple, will require absolutely no attention and will indicate rigorously correct time. There are innumerable devices of all kinds which are either now employed or can be supplied, and by operating them in this manner I may be able to offer a great convenience to the whole world with a plant of no more than 10,000 horse power. The introduction of this system will give opportunities for invention and manufacture such as have never presented themselves before.

"Knowing the far-reaching importance of this first attempt and its effect upon future development, I shall proceed slowly and carefully. Experience has taught me not to assign a term to enterprises the consummation of which is not wholly dependent on my own abilities and exertions. But I am hopeful that these great realizations are not far off, and I know that when this first work is completed they will follow with mathematical certitude.

"Toward the close of 1898 a systematic research, carried on for a number of years with the object of perfecting a method of transmission of electrical energy through the natural medium, led me to recognize three important necessities: First, to develop a transmitter of great power; second, to perfect means for individualizing and isolating the energy transmitted; and, third, to ascertain the laws of propagation of currents through the earth and the atmosphere. Various reasons determined me to select for my experimental investigations the large plateau at Colorado Springs, two thousand metres above sea level, which I reached late in May, 1899.

Tesla's First Important Discovery.

"I found the earth was literally alive with electrical vibrations, and soon I was deeply absorbed in this interesting investigation. No better opportunities for such observations as I intended to make could be found anywhere. Colorado is a country famous for the natural displays of electric force. In that dry and rarefied atmosphere the sun's rays beat the objects with fierce intensity. I raised steam, to a dangerous pressure, in barrels filled with concentrated salt solution, and the tinfoil coatings of some of my elevated terminals shrivelled up in the fiery blaze. An experimental high-tension transformer, carelessly exposed to the rays of the setting sun, had most of its insulating compound melted out and was rendered useless. Aided by the dryness and rarefaction of the air, the water evaporates as in a boiler, and static electricity is developed in abundance. Lightning discharges are, accordingly, very frequent and sometimes of inconceivable violence. On one occasion approximately twelve thousand discharges occurred in two hours, and all in a radius of certainly less than fifty kilometres from the laboratory. Many of them resembled gigantic trees of fire with the trunks up or down.

"In the latter part of the same month I noticed several times that my instruments were affected stronger by discharges taking place at great distances than by those near by. This puzzled me very much. What was the cause? A number of observations proved that it could not be due to the differences in the intensity of the individual discharges, and I really ascertained that the phenomenon was not the result of a varying relation between the periods of my receiving circuits and those of the terrestrial disturbances. One night, as I was walking home with an assistant, meditating over these experiences, I was suddenly staggered by a thought.

"Once before it had presented itself to me, but I had dismissed it as absurd and impossible. Now I banished it again. Nevertheless, my instinct was aroused and somehow I felt that I was nearing a great revelation.

Experimenting with Stationary Waves.

"It was on the third of July—the date I shall never forget—when I obtained the first decisive experimental evidence of a truth of overwhelming importance for the advancement of humanity. A dense mass of strongly charged clouds gathered in the west, and toward the evening a violent storm broke loose which, after spending much of its fury in the mountains, was driven away with great velocity over the plains. Heavy and long persisting arcs formed almost in regular time intervals. My observations were now greatly facilitated and rendered more accurate by the experiences already gained. I was able to handle my instruments quickly and I was prepared. The recording apparatus being properly adjusted, its indications became fainter and fainter with the increasing distance of the storm, until they ceased altogether. I was watching in eager expectation. Surely enough, in a little while the indications again began, grew stronger and stronger and, after passing through a maximum, gradually decreased and ceased once more. Many times, in regularly recurring intervals, the same actions were repeated until the storm, which, as evident from simple computations, was moving with nearly constant speed, had retreated to a distance of about three hundred kilometres. Nor did these strange actions stop then, but continued to manifest themselves with undiminished force. Subsequently, similar observations were also made by my assistant, Mr. Fritz Lowenstein, and shortly afterward several admirable opportunities presented themselves which brought out still more forcibly and unmistakably the true nature of the wonderful phenomenon. No doubt whatever remained: I was observing stationary waves.

Confidential Chats Across Oceans.

"With these stupendous possibilities in sight, with the experimental evidence before me that their realization was henceforth merely a question of expert knowledge, patience and skill, I attacked vigorously the development of my magnifying transmitter, now, however, not so much with the original intention of producing one of great power as with the object of learning how to construct the best one. This is, essentially, a circuit of very high self-induction and small resistance which in its arrangement, mode of excitation and action, may be said to be the diametrically opposite of a transmitting circuit typical of telegraphy by Hertzian or electromagnetic radiations. It is difficult to form an adequate idea of the marvellous power of this unique appliance, by the aid of which the globe will be transformed. The electromagnetic radiations being reduced to an insignificant quantity, and proper conditions of resonance maintained, the circuit acts like an immense pendulum, storing indefinitely the energy of the primary exciting impulses and impressing upon the earth and its conducting atmosphere uniform harmonic oscillations of intensities which, as actual tests have shown, may be pushed so far as to surpass those attained in the natural displays of static electricity.

"When the great truth accidentally revealed and experimentally confirmed is fully recognised it will be seen that this planet, with all its appalling immensity, is to electric currents virtually no more than a small metal ball, and that by virtue of this fact many possibilities, each baffling imagination and of incalculable consequence, are rendered absolutely sure of accomplishment. When the first plant is inaugurated it will be shown that a telegraphic message, almost as secret and non-interferable as a thought, can be transmitted to any terrestrial distance, the sound of the human voice, with all its intonations and inflections faithfully and instantly reproduced at any other point of the globe and the energy of a waterfall made available for supplying light, heat or motive power anywhere—on sea, or land, or high in the air."

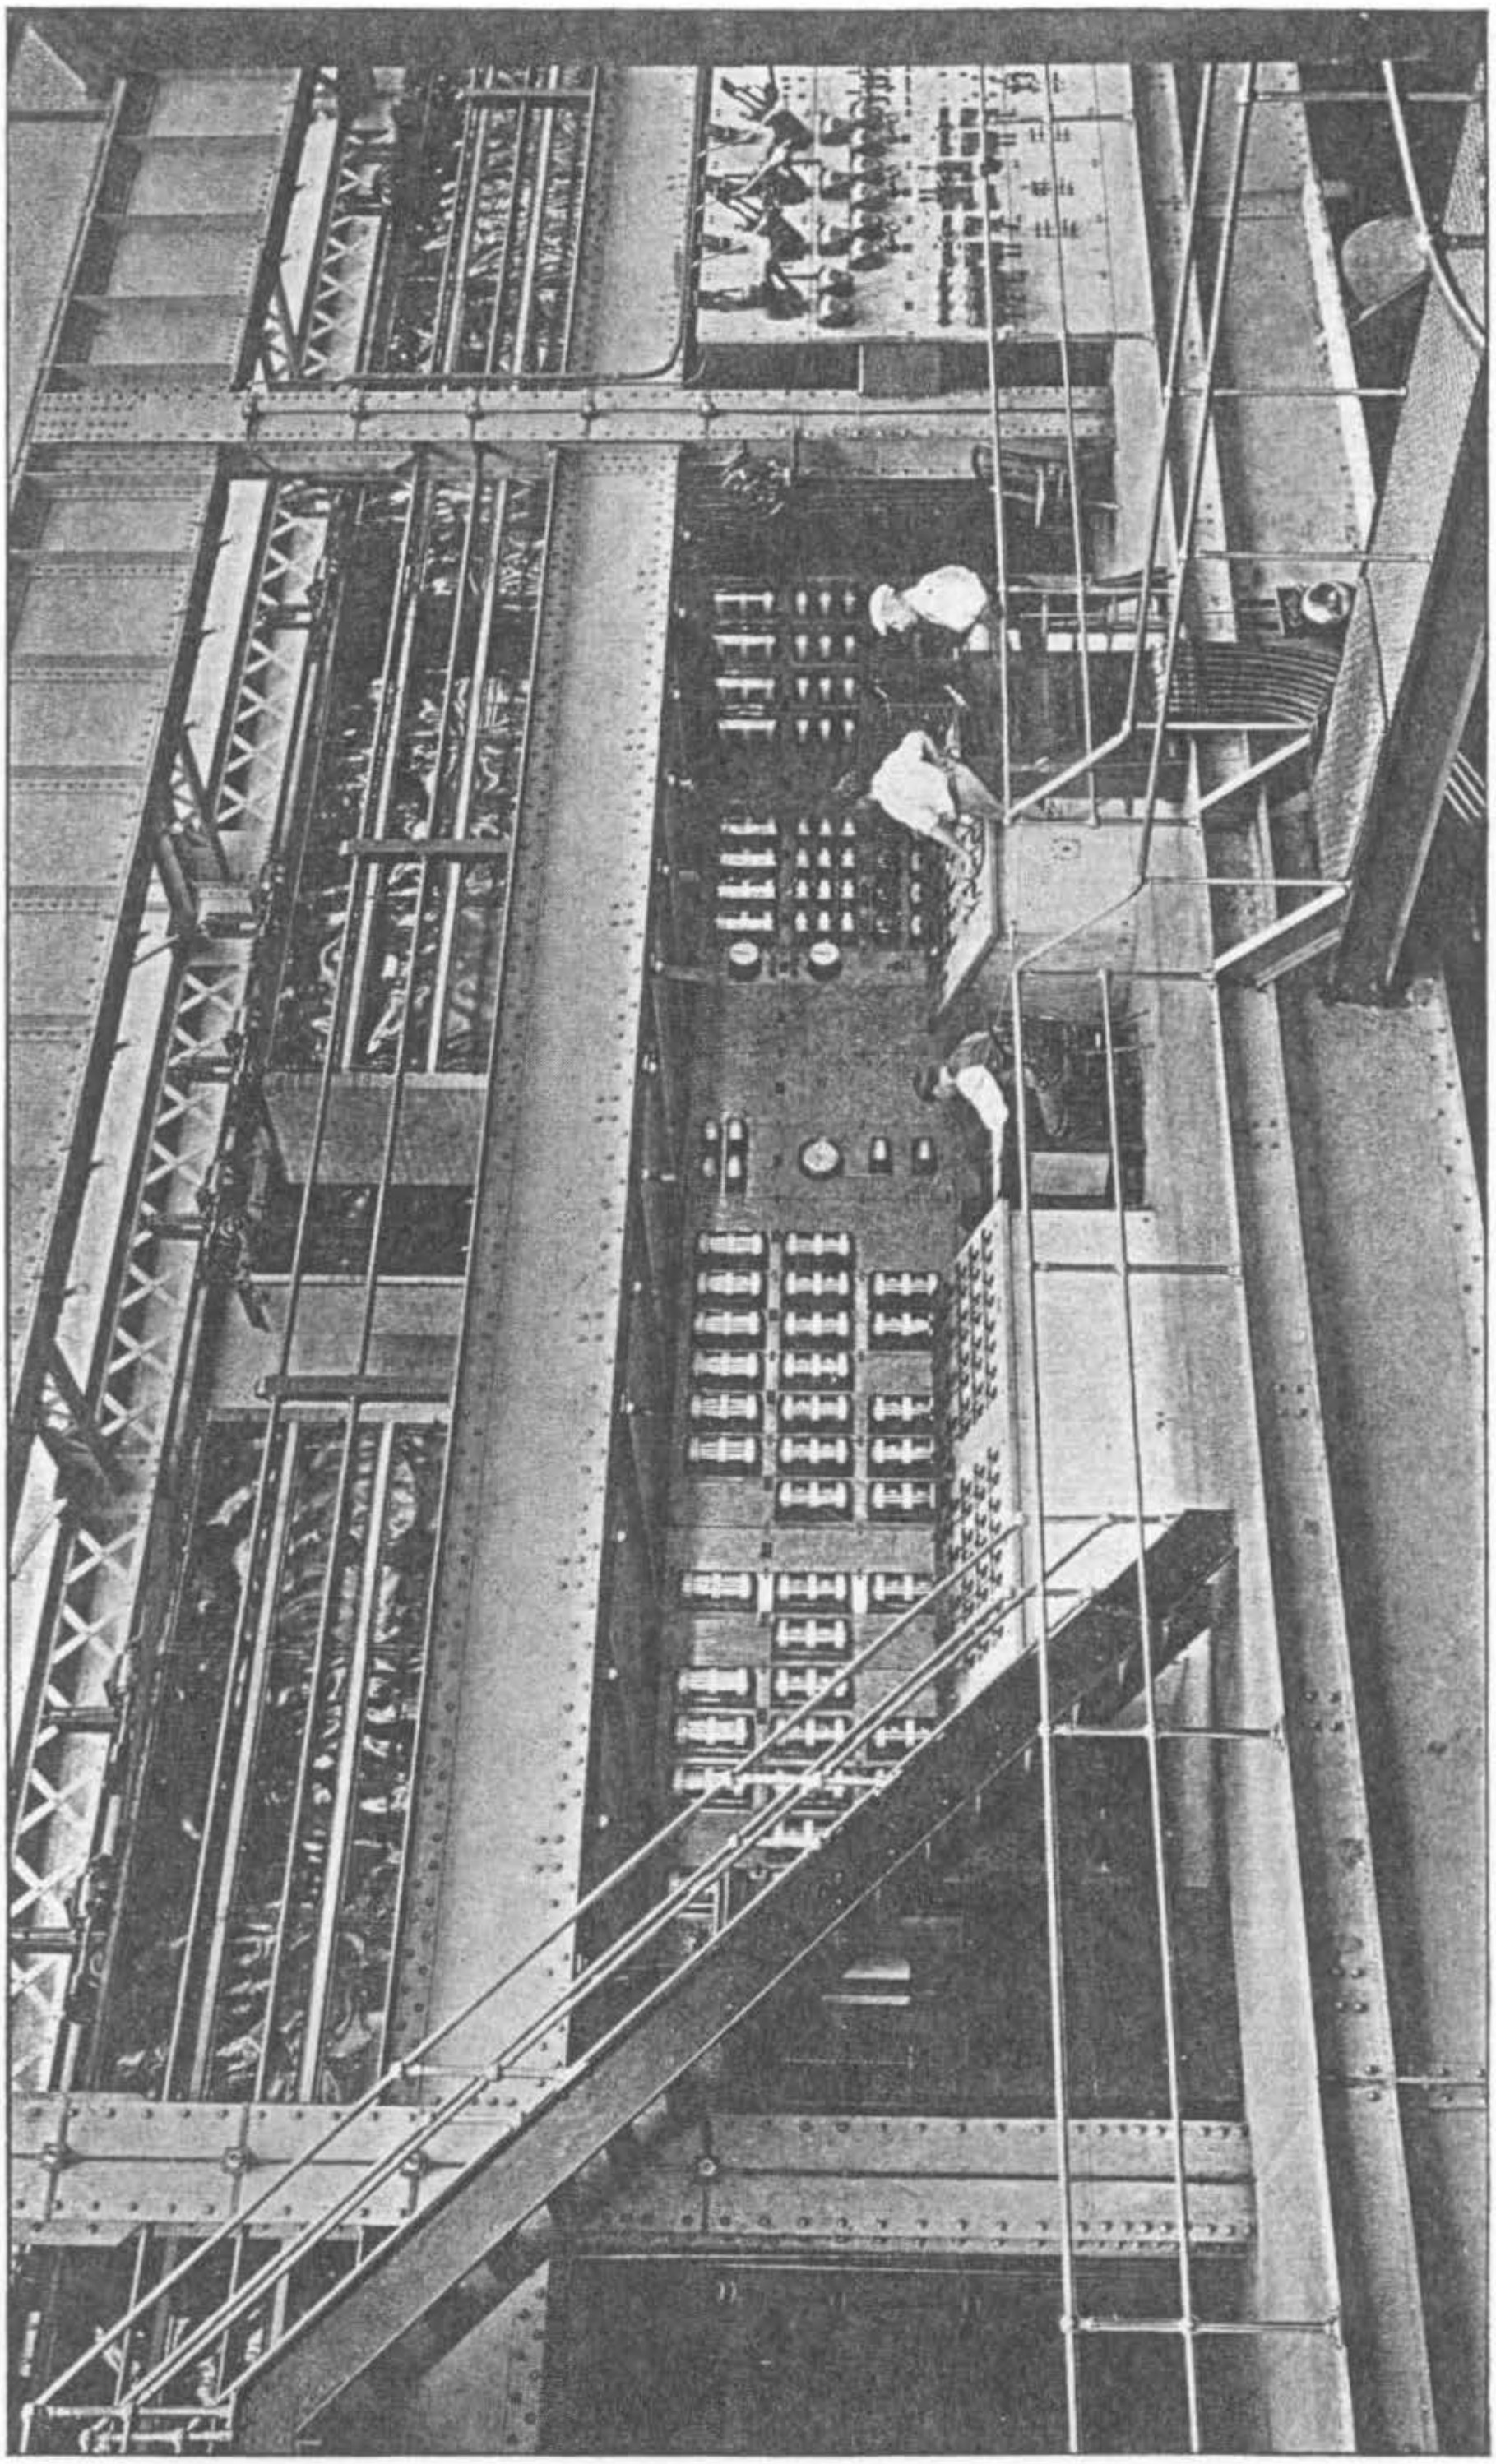
VOL. XXVI JUNE, 1904 No. 2

THE DEVELOPMENT OF ELECTRIC POWER TRANSMISSION

By Lewis Buckley Stillwell



IN October, 1886, in a small room on the top floor of an old house in Pittsburgh, Pa., three hundred incandescent lamps were lighted continuously for a period of about two weeks by alternating current, transmitted a distance slightly exceeding two miles, over a single-phase circuit, comprising two copper wires of No. 4 B. & S. gauge. The potential used was 1000 volts, the frequency about 130 cycles per second, and the lamps were connected in parallel to the secondary circuits of half a dozen transformers. The ratio of transformation was 1000 to 50.

This was the first instance, in America at least, in which alternating current was used in transmitting electric energy beyond laboratory distances for the supply of translating devices connected in multiple arc. The alternator used to supply the power was driven by belt from a line shaft, to which a high-speed automatic engine was connected, and this generating plant was located in a shop of the Westinghouse Electric & Manufacturing Company on the banks of the Allegheny River within a mile of the site of old Fort Duquesne.

It was the writer's fortune to be detailed to watch those lamps during twelve hours out of every twenty-four during the test,—his first practical experience in applied electricity,—and he vividly recalls the keen interest with which everybody who had anything to do with the work observed the results. In the history of American industrial progress the Lawrenceville test, as it has been called, was an event of no little importance. To Stanley and Shallenberger, for the technical skill and for the patient work which produced the apparatus, and to George Westinghouse, whose far-sighted enterprise realised possibilities at that time scouted by others, all those who now are deriving benefit from the wonderfully extended use of alternating currents are under an obligation which they should be glad to recognise.

Prior to the Lawrenceville test, distribution of electric energy to lamps or motors had been accomplished by continuous-current systems operating at potentials of 110 to 220 volts. The

three-wire system invented by Edison, permitting the use of a potential of 220 volts, was coming into use for general purposes in the larger cities, and was regarded as the highest potential available for such work. The general significance of the results of the Lawrenceville test was keenly realised; but the difficulties encountered in attempting to develop single-phase, alternating-current motors, capable of operation at the high frequency then used, practically prevented for a number of years the use of alternating current for power purposes. It was, however, rapidly developed and extensively applied in the field of incandescent lighting.

Tesla patented the polyphase alternating-current motor in 1888, but this also was slow in development, owing largely to the fact that for a long time in America efforts were principally directed toward the development of a motor adapted to the high frequency of 130 cycles per second. In 1890 the Westinghouse Company adopted as standards two lower frequencies,—60 cycles per second and 30 cycles per second. The step facilitated greatly the development of satisfactory polyphase motors, and not long afterward they began to come into commercial use.

The commercial significance of the Lawrenceville test is strikingly illustrated—although the impression conveyed by the illustration is a somewhat exaggerated one—by the story of the manager of a gold mine in Colorado, who, in 1896, was able to operate a stamp mill located at a distance of about three miles from his water-power by alternating current transmitted to the motor over a circuit consisting of iron telephone wire of ordinary size. This was accomplished by using a high-potential single-phase alternating current. The cost of the telephone wire was about sixty dollars. It is stated that an estimate for a continuous-current plant to do the same work had been submitted by a manufacturer of continuous-current machinery, and that these plans called for the installation of copper circuits costing more than sixty thousand dollars.

United States Census Bulletin No. 5, recently issued, places us for the first time in possession of many important and extremely interesting statistical facts relating to the use of electricity for light

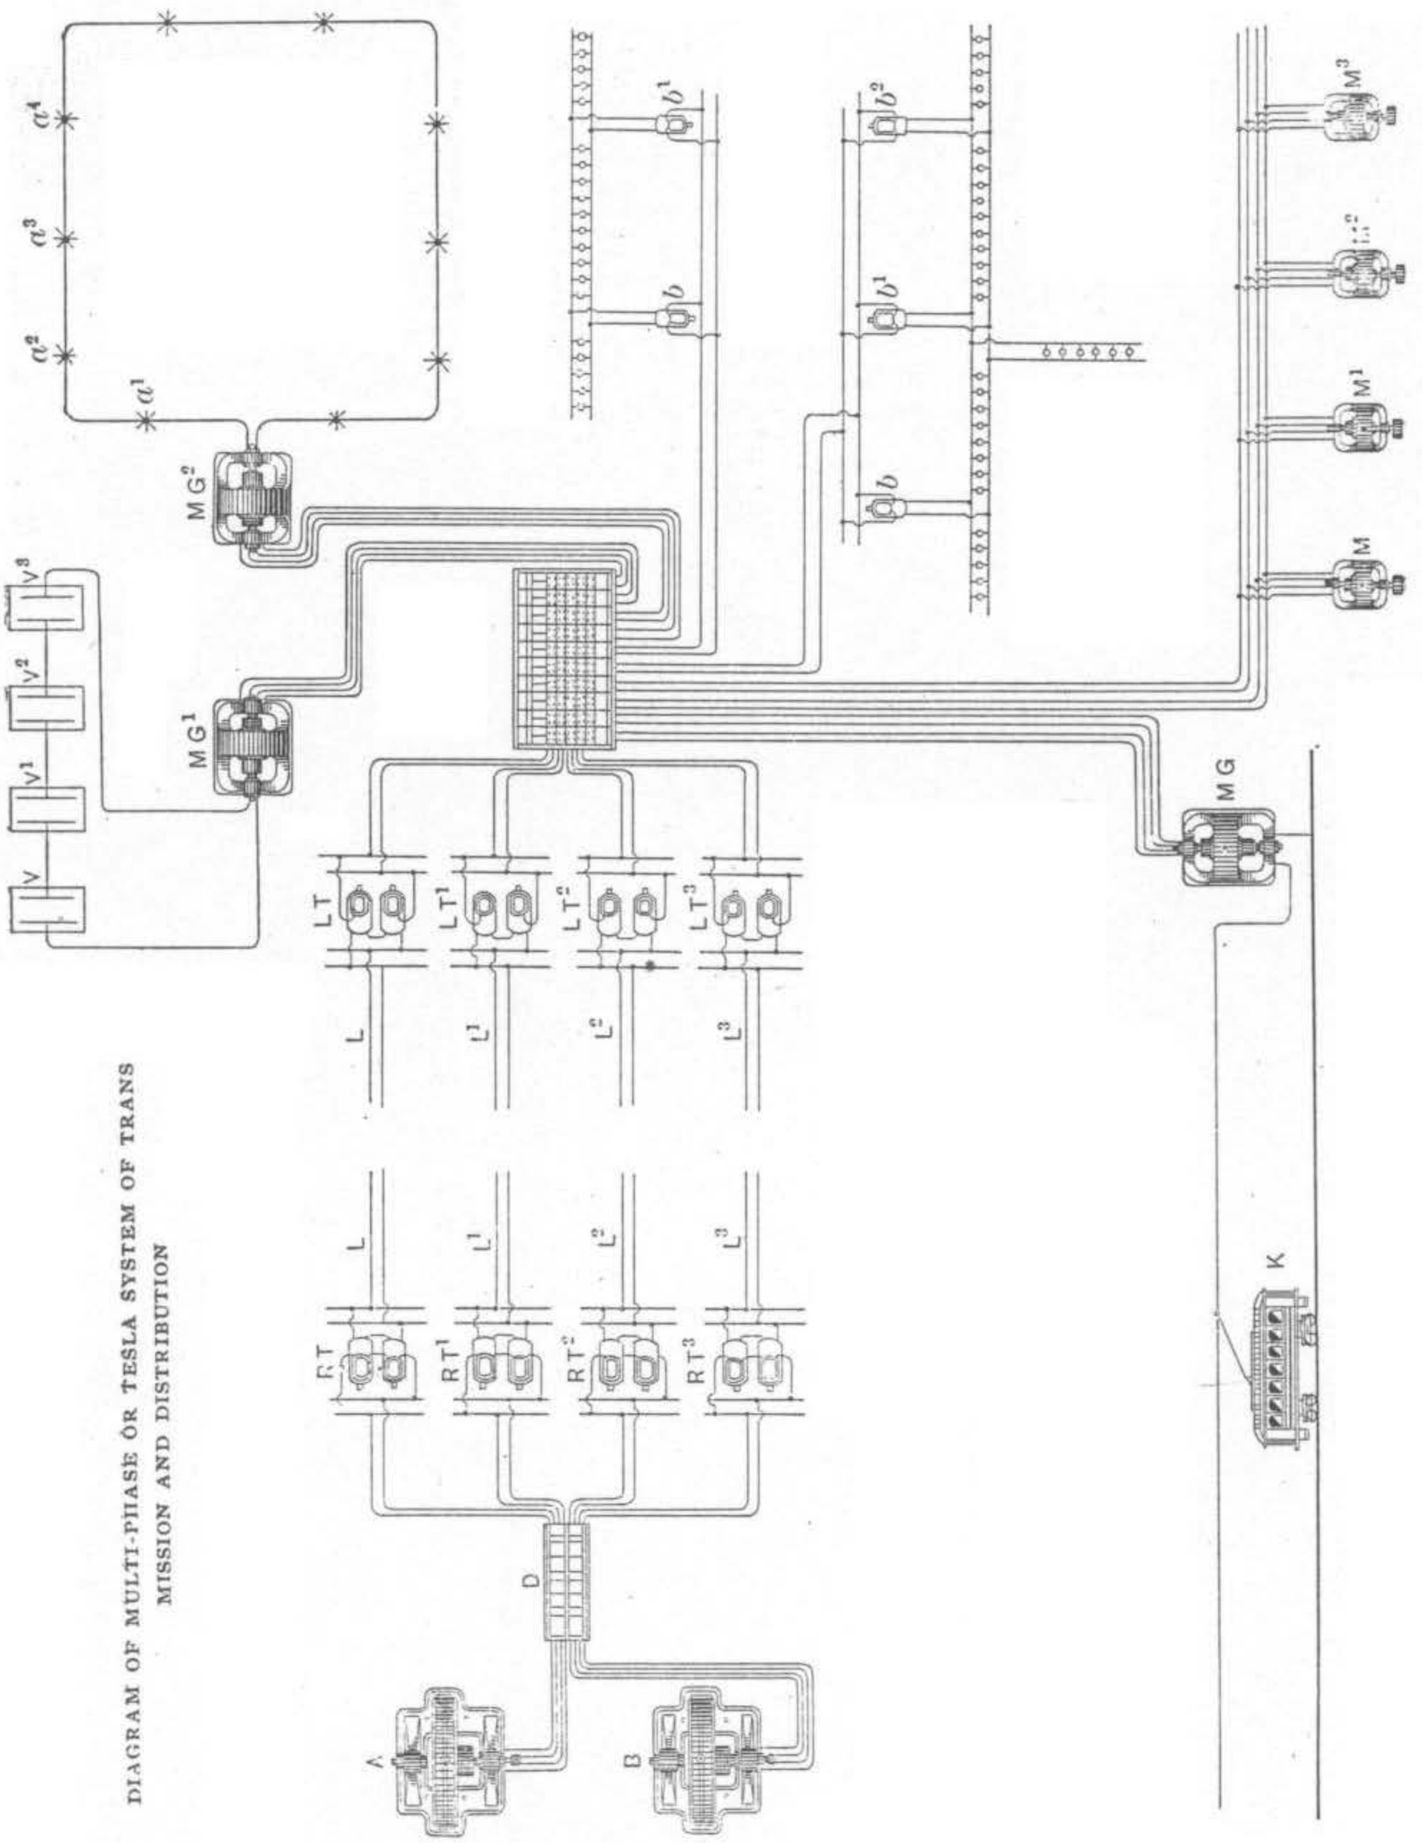

DIAGRAM OF MULTI-PHASE OR TESLA SYSTEM OF TRANS MISSION AND DISTRIBUTION

and power purposes in the United States exclusive of its use for traction purposes. Table I. of this bulletin cannot be improved by further condensation, and is, therefore, here reproduced.

It will be noted that of the aggregate output of dynamos installed in central stations which supply power exclusively for lighting and power purposes, which aggregate amounts to 1,624,480 horse-power, the rated output of alternating-current dynamos constitutes more than 60 per cent. A considerable number of electric power plants, installed primarily for the purpose of operating street and electric railways, also supply current for lighting and power purposes, and if these be added to those which furnish power for lighting and power purposes only, the grand aggregate of central stations becomes 3738, the number of arc lamps 419,561, the number of incandescent lamps 19,636,729, and the total income from the sale of current $90,458,420.

The relative commercial importance of the central electric station industry and gas industry is shown in Table II., which also is reproduced from Census Bulletin No. 5.

The peculiar value of alternating-current development resulting from the reduction in cost of distribution which is effected by this class of apparatus is illustrated by the fact that 75 per cent. of the central electric stations are in towns of less than 5000 inhabitants, as compared with 22.8 per cent. of the gas plants.

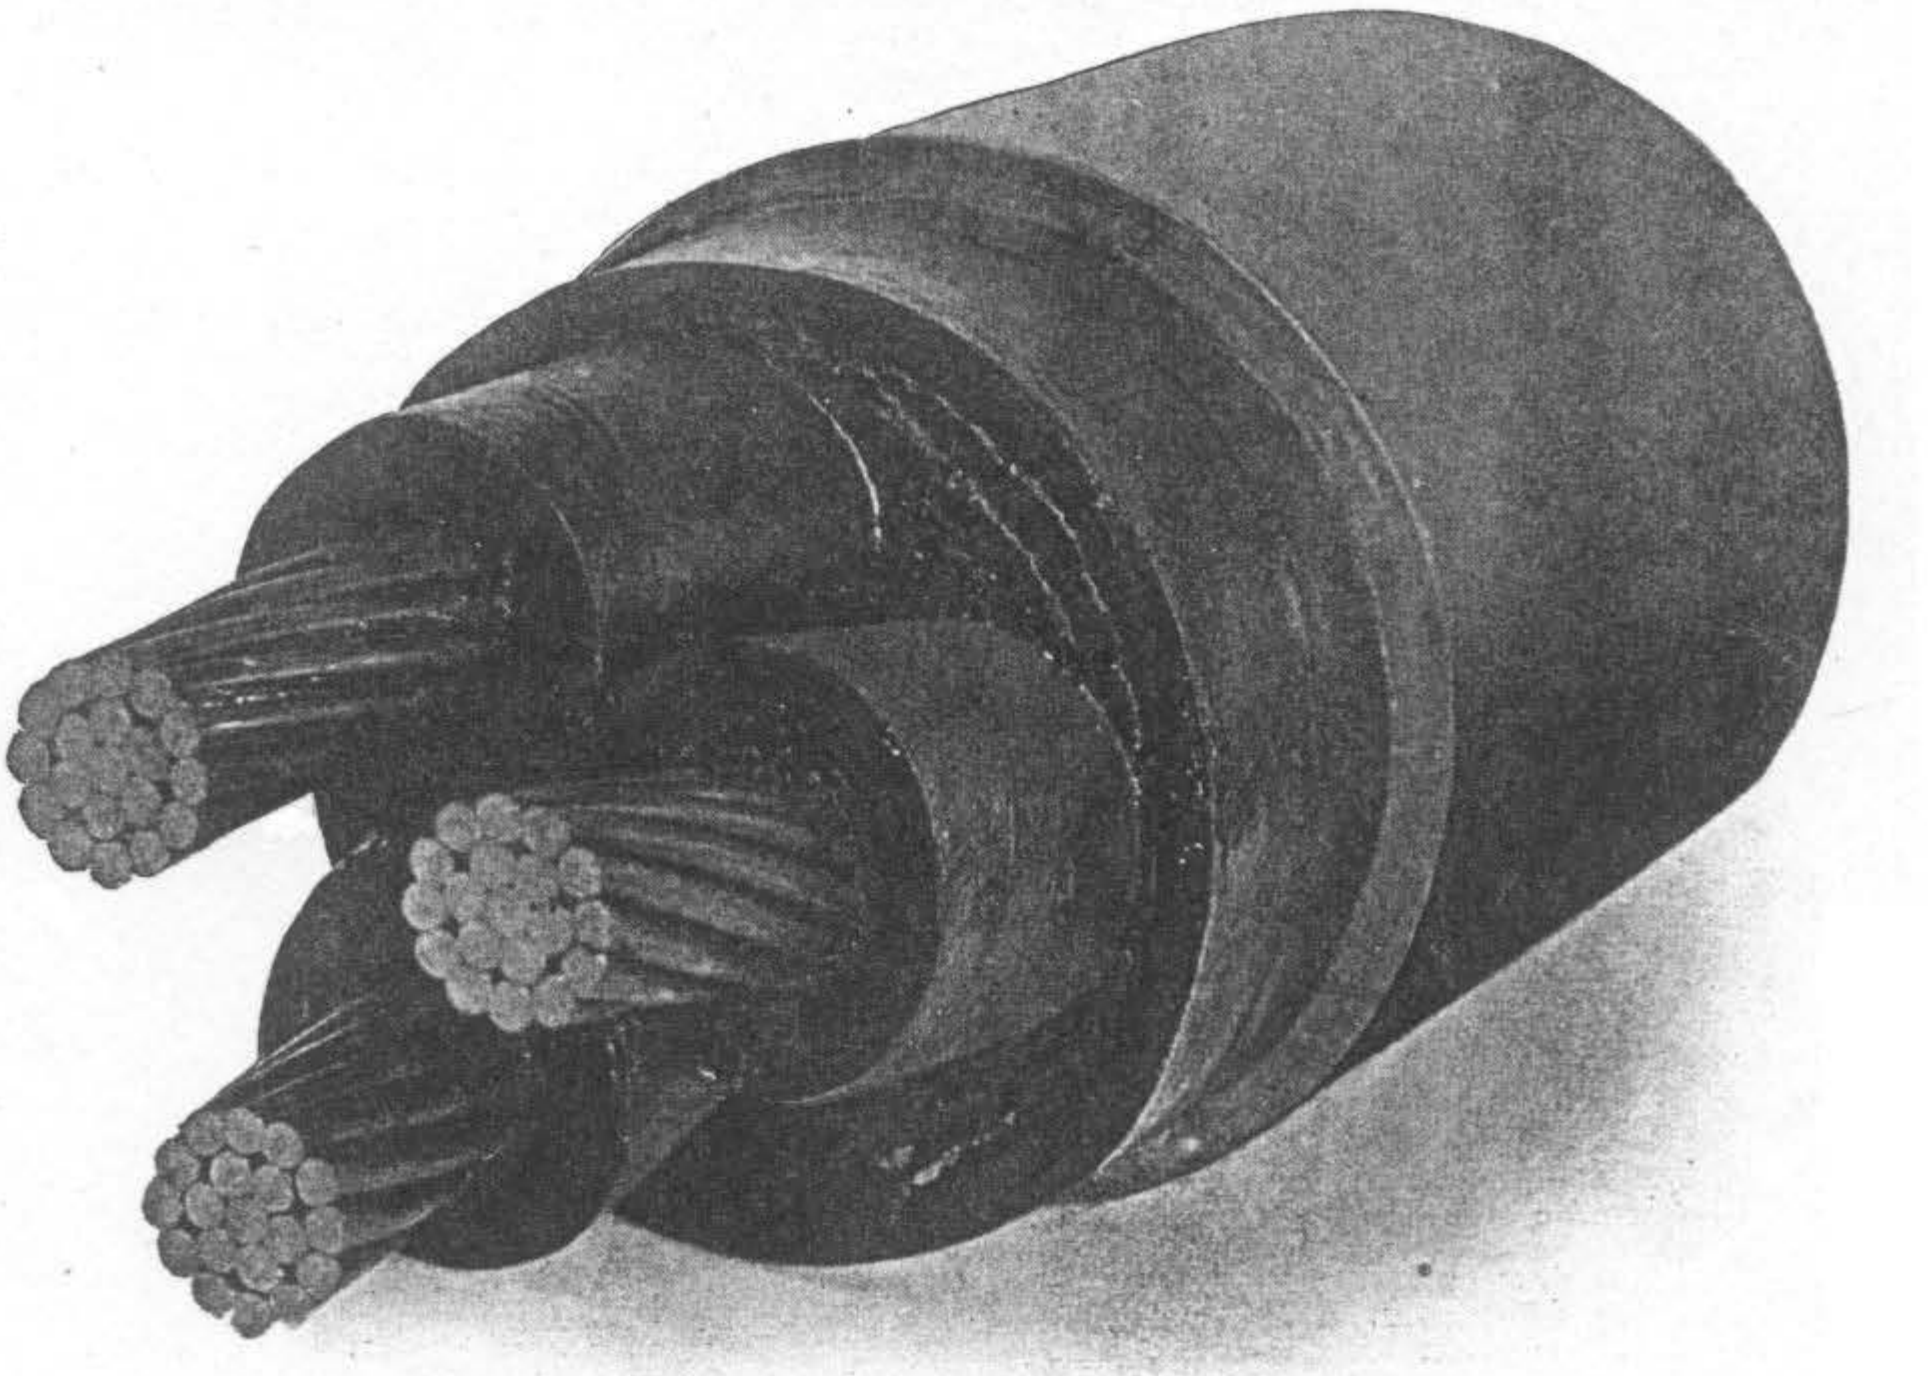
As regards stationary motors, the aggregate number installed is 101,064, and their aggregate horse-power amounts to 624,686. The total rated horse-power of steam engines and water-wheels used to drive dynamos is 1,772,813, of which total 77.8 per cent. are the indicated capacity of steam engines and 22.2 per cent. the stated capacity of water-wheels.

TABLE III.—PERCENTAGES THAT THE NUMBER AND HORSE-POWER OF THE DIFFERENT VARIETIES OF DYNAMOS ARE OF THE TOTAL STATIONS IN 1902

Kind of Dynamo	Total
Total—	
Number	100.0
Horse-power	100.0
Direct-current, constant voltage—	
Number	30.6
Horse-power	27.2
Direct-current, constant amperage—	
Number	28.3
Horse-power	12.0
Alternating and polyphase current—	
Number	41.0
Horse-power	60.8

The relative number of dynamos and relative aggregate horse-power of alternators, as compared with direct-current, constant voltage machines and direct-current, constant ampèrage machines, are shown in Table III.

It will be noted that the average alternator is a much larger machine than the average direct-current machine of either of the two direct-current classes.



It is impracticable within the limits of this article to attempt anything like a comprehensive review of the development of alternating-current apparatus for transmission and distribution of power which shall refer even briefly to the many small steps which, in the aggregate, have contributed so much to the march of progress; but in brief retrospect reference to a few of the more important steps may serve to emphasise the remarkable rapidity which has characterised the evolution of this comparatively young, but very vigorous, addition to present industrial assets.

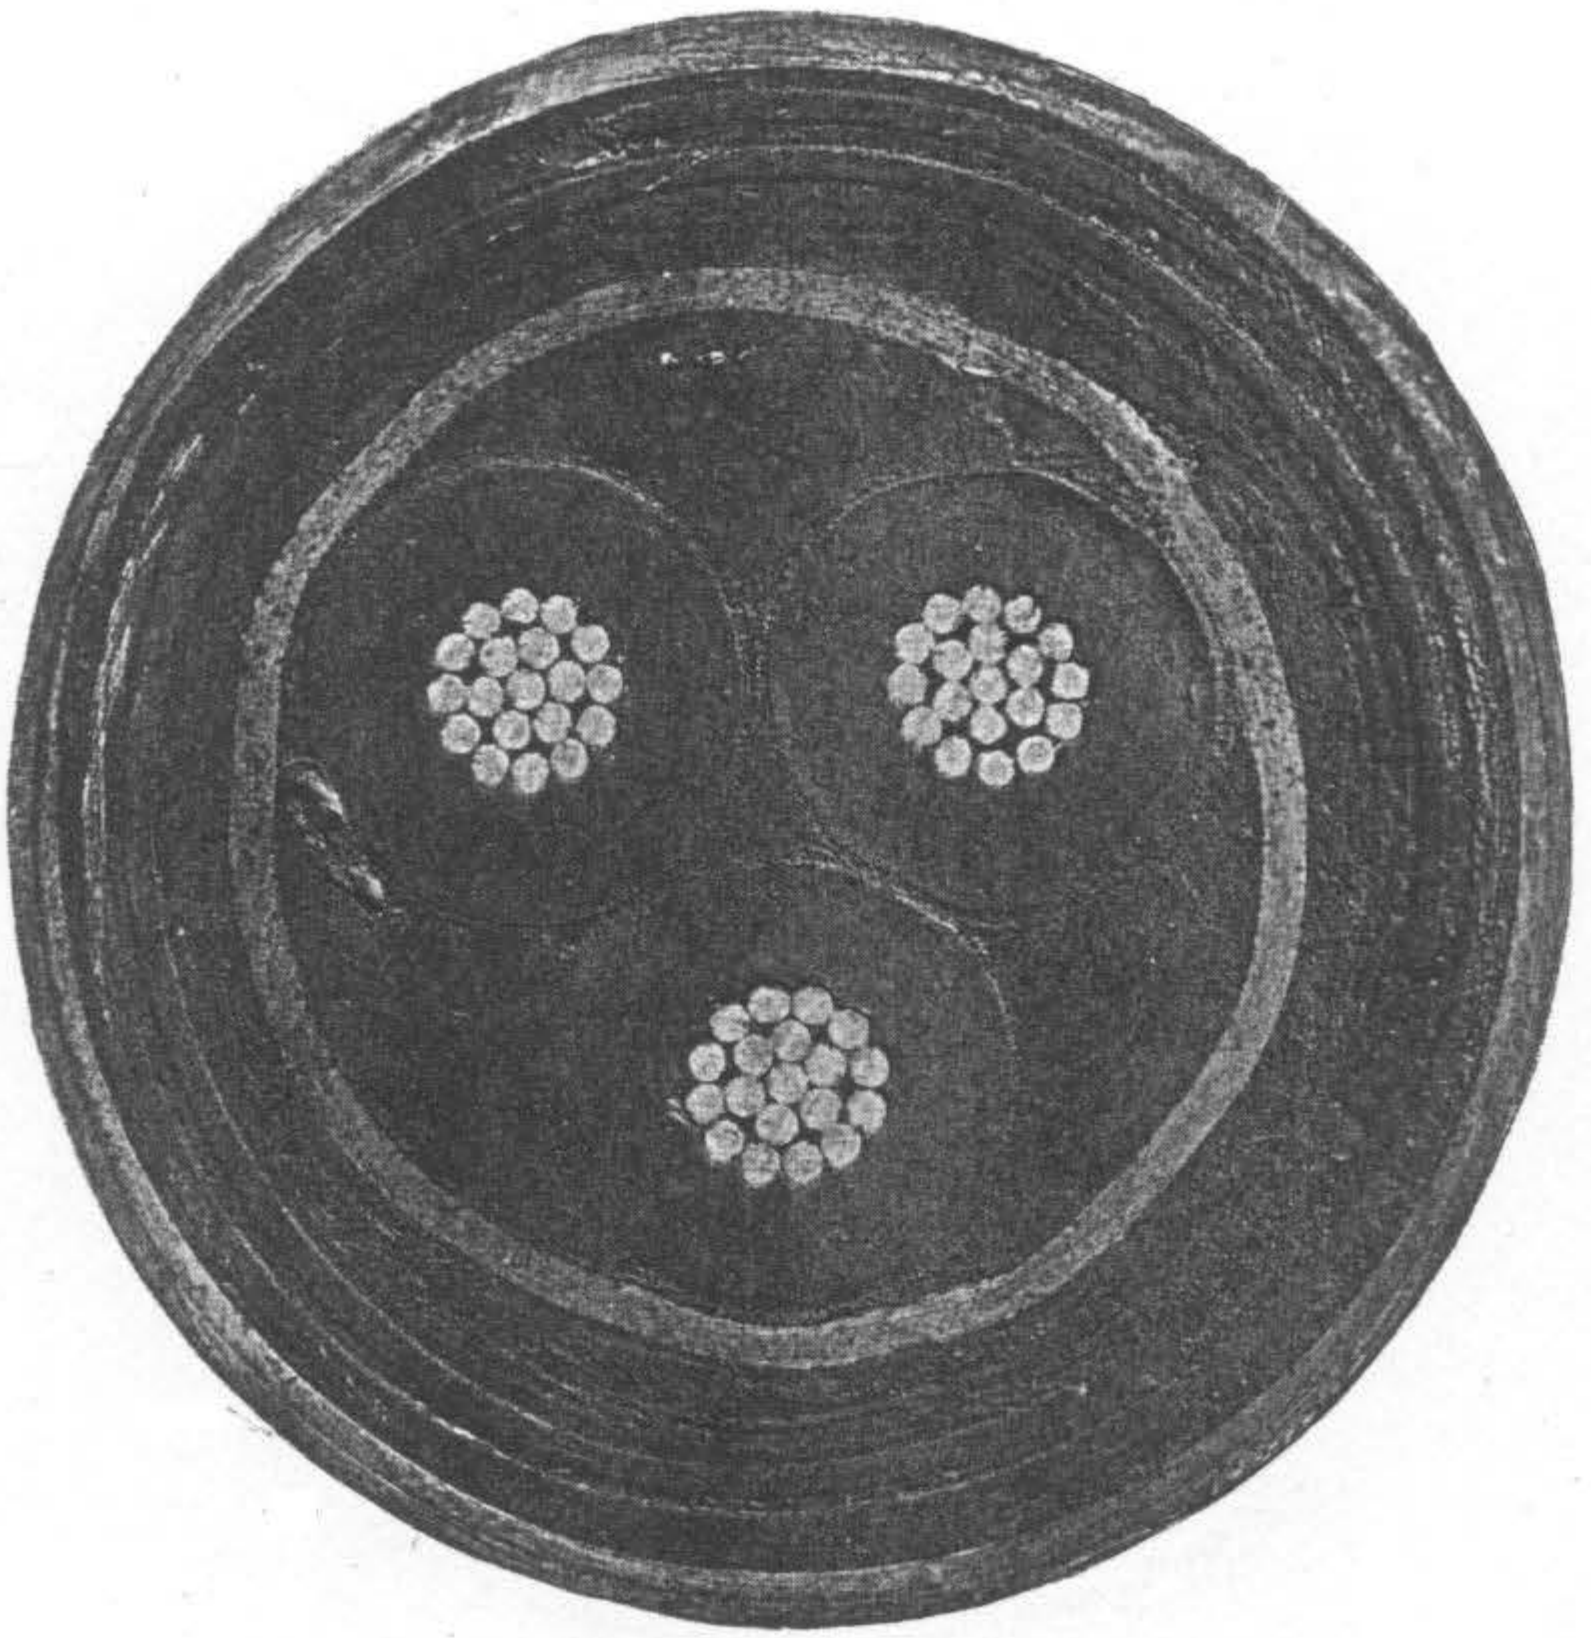
In 1890 the celebrated Frankfort-Lauffen transmission illustrated and emphasised the possibilities of high-potential alternating current in bridging

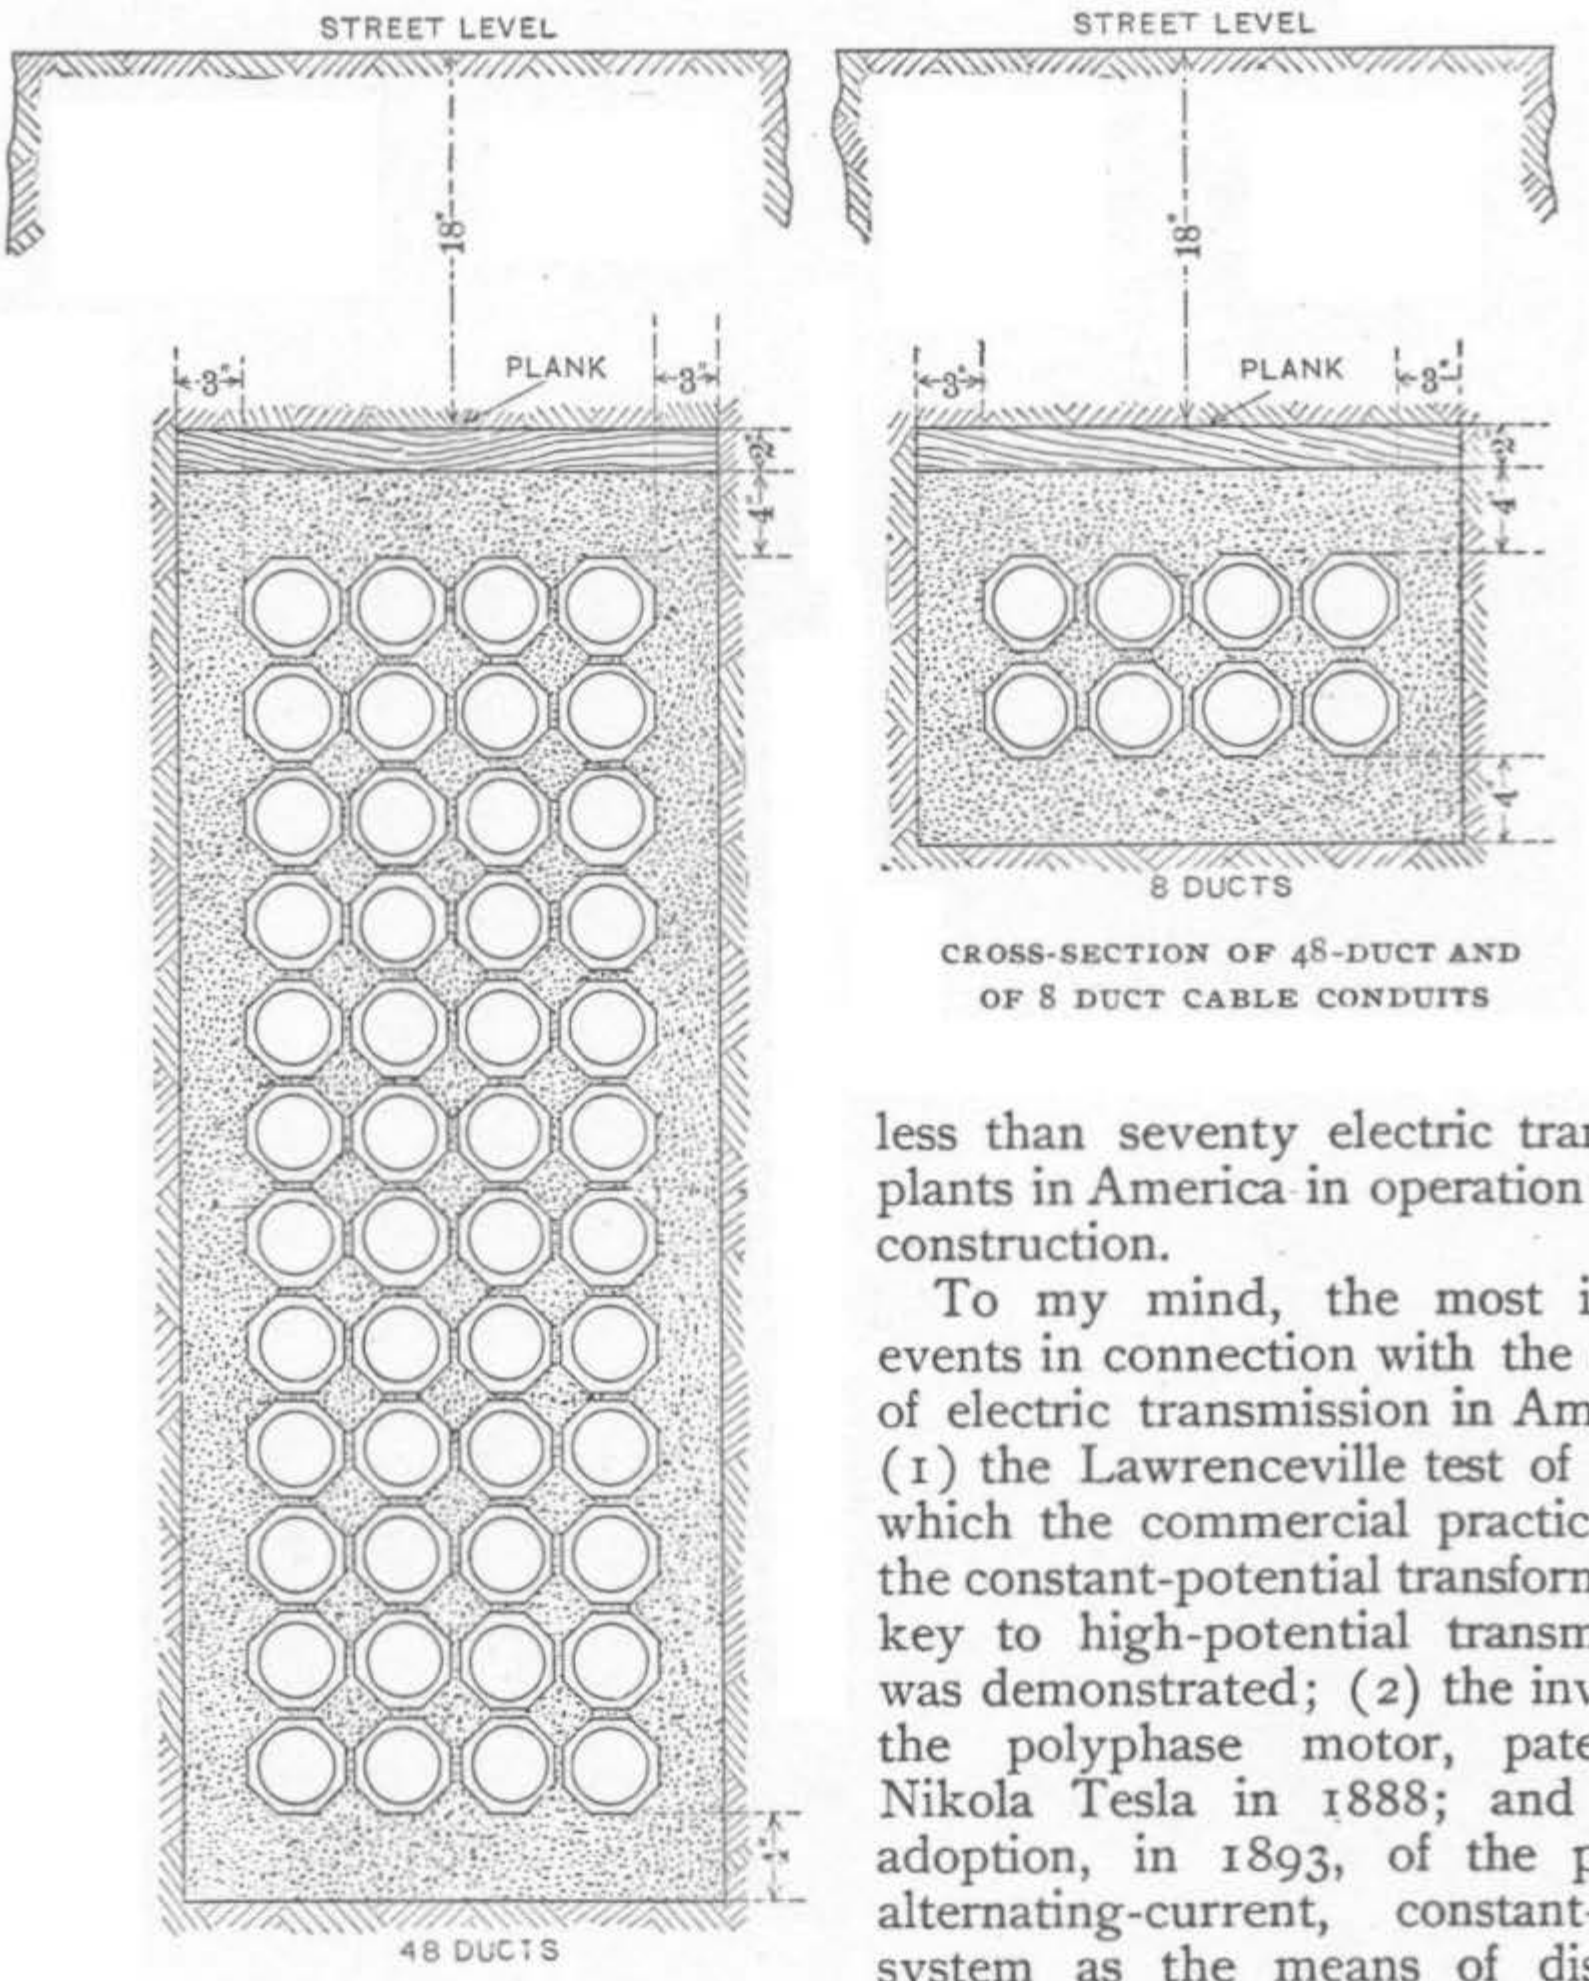
A FULL-SIZE SECTION OF THREE-CONDUCTOR, PAPER-INSULATED CABLE FOR 11,000 VOLT THREE-PHASE TRANSMISSION USED BY THE INTERBOROUGH RAPID TRANSIT CO., NEW YORK



great distances. The potential used during the test was at times 14,000 volts, and at other times 28,000 volts; the distance was 110 miles; the amount of power was small,—about 200 H. P. The transmission was in no sense a commercial success, nor, indeed, was it expected to be. It served its purpose, however, of demonstrating, upon a scale sufficiently large, the possibility of insulating a long circuit effectively for potentials very high as compared with anything previously attempted, and it also served the purpose of concentrating attention in many quarters upon the subject of electric power transmission, and so contributed in a striking and effective manner to the commercial development of a relatively new art.

In America the first important attempt at transmitting power for commercial purposes at a potential materially exceeding the 3000 volts used at Telluride, Colorado, in 1890, was the installation of the plant at San Bernardino and Pomona, in Southern California. The potential used was 10,000 volts; the distance from the water-power to San Bernardino was twenty-nine miles.

On May 2, 1893, Mr. George H. Winslow, engineer in charge of the plant, connected the Pomona circuit in series with that to San Bernardino and transmitted about 100 E. H. P. to San Bernardino, a distance of forty-two and one-half miles, this being by far the greatest distance attained in America up to that time.



About that time, in various shops and laboratories of America and Europe, the polyphase motor was fast taking commercial form, and at the Chicago Exposition of 1893 some striking and important exhibits of polyphase apparatus were shown in operation. Among these was a complete power transmission

plant, comprising a 375-KW, two-phase alternator, an outfit of step-up and step-down transformers connected by a high-potential circuit, a 375-KW rotary converter delivering continuous current at 550 volts, a 60 H. P. synchronous motor, and a number of induction motors, ranging from 1 H. P. to 15 H. P. The system was two-phase, the frequency 30 cycles per second, and the potential of the transmission circuit 10,000 volts. At the receiving end of the line incandescent lamps were supplied through transformers, and arc lamps were fed by continuous current from the rotary converter. Continuous current from the rotary converter was also used to operate direct-current motors. The diagram on page 100, which is reproduced from a descriptive circular published at the time, shows that this plant embodied all essential features of the latest transmission plants, except that two-phase circuits were employed instead of the three-phase plan now generally preferred. The Germans were first to perceive clearly the advantages of the three-phase system, as compared with the two-phase system, and to push the development of three-phase apparatus. Dobrovolski showed me, in Berlin, in 1890,—possibly as early as 1889,—a three-phase motor probably capable of developing a quarter of a horse-power. In America, Bell, of the General Electric Company, installed the first three-phase plant at Redlands, in California, in 1893.

FULL SIZE RUBBER-INSULATED, STEEL-ARMOURED, THREE-CONDUCTOR CABLE FOR SUBMARINE WORK, USED BY THE INTERBOROUGH RAPID TRANSIT COMPANY OF NEW YORK, UNDERNEATH HARLEM RIVER

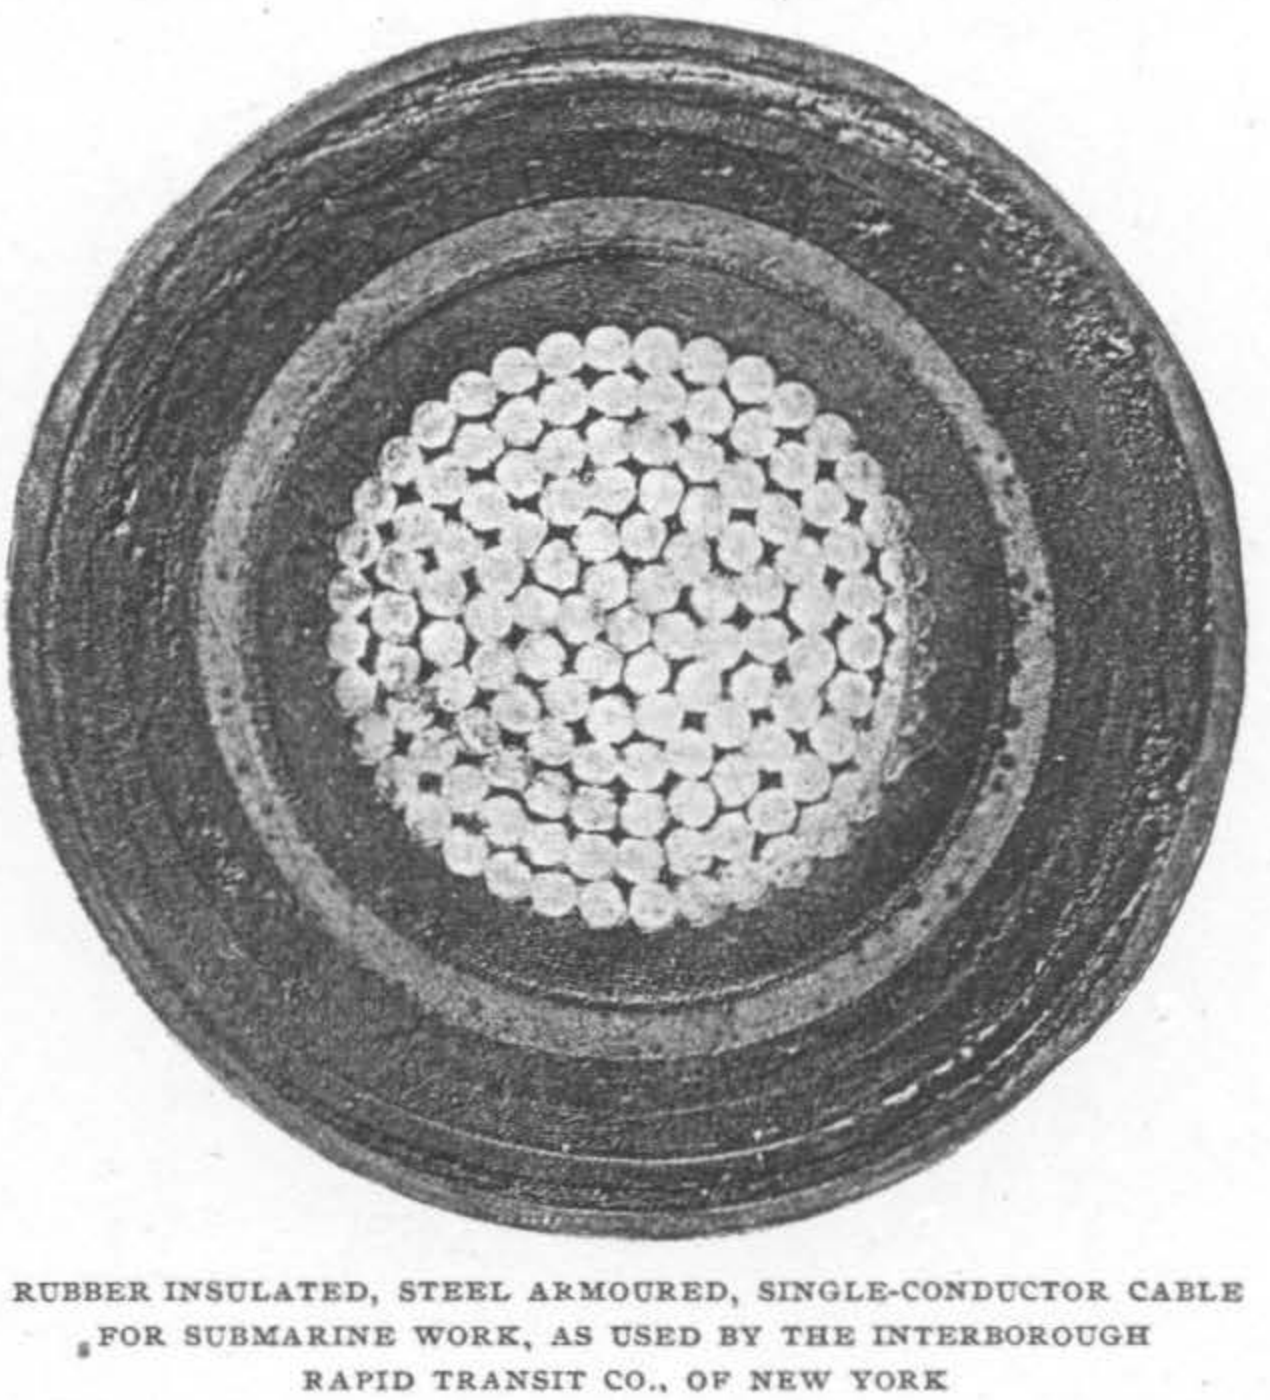
From the autumn of 1892, to October, 1893, the officers and engineers of the Cataract Construction Company were systematically working toward a

CROSS-SECTION OF 48-DUCT AND OF 8 DUCT CABLE CONDUITS

decision of the great engineering question of the best method of utilising the power of Niagara, and in the month last mentioned they executed a contract for polyphase alternating-current machinery to be installed in a central station and utilised in generating electricity to be distributed for power and lighting purposes. The decision of the Cataract Company, which had studied the subject exhaustively, both in Europe and America, had a notably stimulating effect, and less than two years later, in the Niagara power number of CASSIER'S MAGAZINE, issued in July, 1895, the late S. Dana Greene, in a very interesting article upon "Distribution of Niagara Energy," was able to list not less than seventy electric transmission plants in America in operation or under construction.

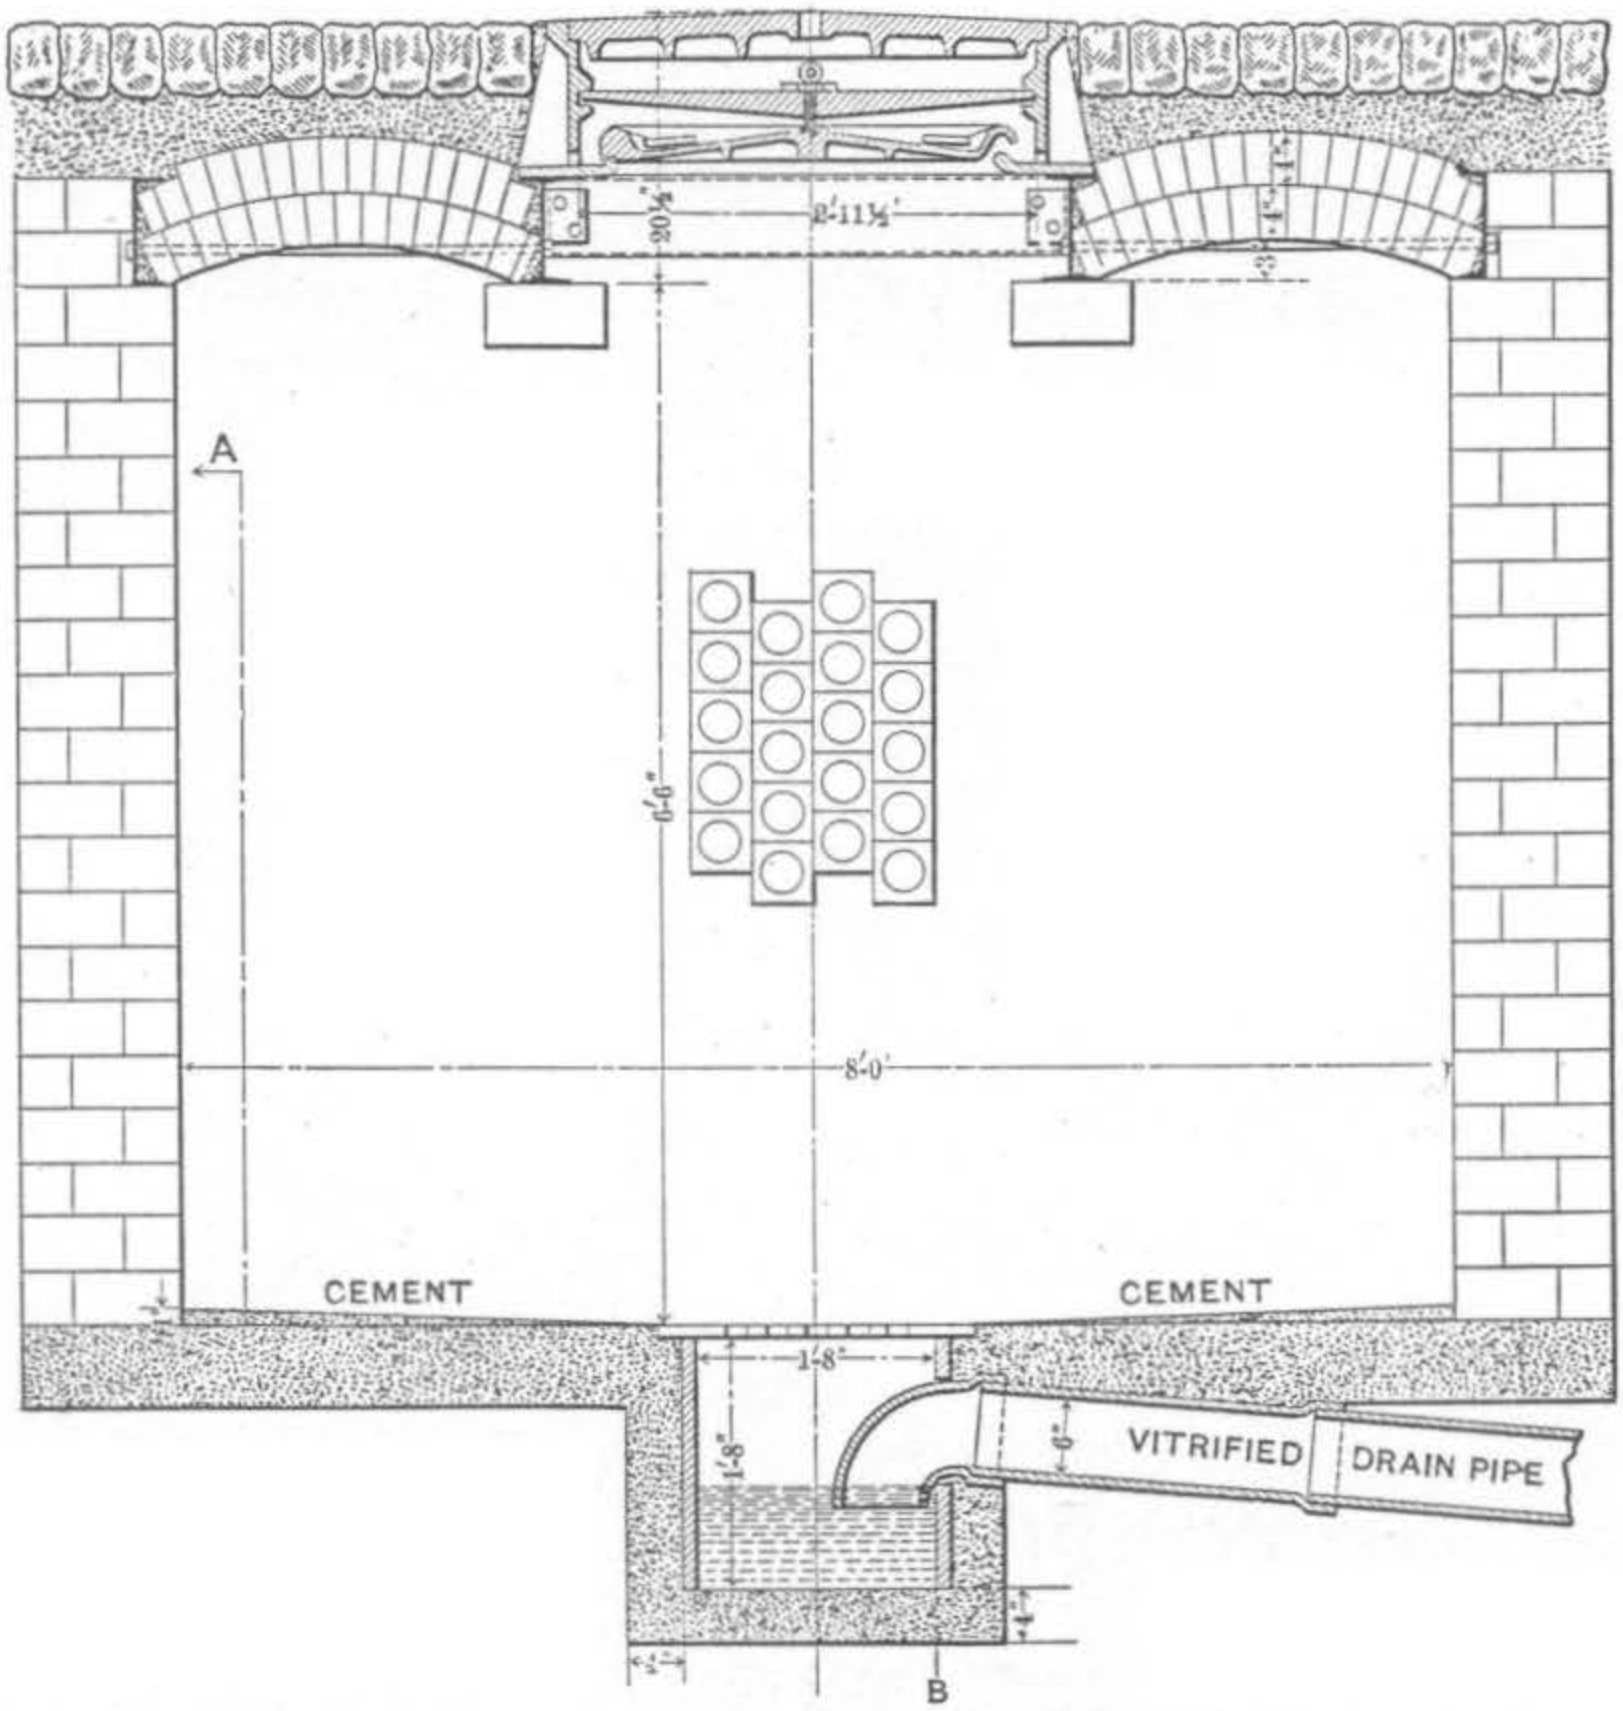
To my mind, the most important events in connection with the evolution of electric transmission in America are (1) the Lawrenceville test of 1886, by which the commercial practicability of the constant-potential transformer,—the key to high-potential transmission,—was demonstrated; (2) the invention of the polyphase motor, patented by Nikola Tesla in 1888; and (3) the adoption, in 1893, of the polyphase alternating-current, constant-potential system as the means of distributing power from Niagara Falls.

The Lawrenceville test demonstrated the possibilities of the transformer in reducing the cost of transmitting circuits; the invention of the polyphase motor furnished the means of utilising the transmitted power for power purposes, and the adoption of polyphase alternating currents by the Cataract Construction Company for the great work at Niagara Falls sealed the commercial success of the system. An excellent meter for alternating currents had been invented and perfected by Shallenberger as early as 1888, and Elihu Thomson also had produced an effective meter for the same kind of service.



But the invention of the transformer,

the motor, and the meter left still to be developed much apparatus of prime importance in the construction of the complete and effective plant for transmission and distribution of power by electricity. Switches, operated automatically or otherwise, and adapted to high-potential circuits; insulators for overhead lines and insulation for underground cables; devices for protecting apparatus against the effects of lightning,—all these and other adjuncts, now deemed essential, were still in the future in 1893 so far as heavy power circuits carrying high potentials were concerned, and still in the future also was the question how best to aggregate the complicated apparatus of a transmission system,—one of the great questions of engineering practice which still receives answers varying in respect to important details, but varying far less than they did ten years ago. There remained also the training of men and the development of effective organisations for operation,—a work in itself requiring time, thought, and painstaking effort.



Thanks to Hopkinson, Kapp, Schmid, Brown and others, the art of dynamo design had been developed to a point where it became possible to predetermine the constants of a dynamo, and to design and build in full confidence that the results attained under test would coincide with expectation based upon calculations. The transformer, the motor and the meter placed us in possession of means for delivering and measuring power at a distance; but, as has been indicated, much remained to be done in the development of a reliable system.

It should be noted also that the development of apparatus for electric transmission thus far has been effected necessarily not with reference to fixed ultimate conditions, but with reference to conditions which are constantly changing by reason of the demand for higher and still higher potentials, and by reason of the increased complexity of circuits which results from the growth of existing plants. As the possibility of bringing greater distances becomes apparent, the demand for increased potentials makes itself felt, and every important increase of potential implies corresponding increase in insulation of circuits, including transformers, switches and all devices connected therewith.

Again, as a given power company extends the sale of its product, every additional user of power implies additional apparatus connected to the circuits and increased risk of interruption of the general supply of power to customers of the company. Increase of potential must be met by improvement in insulation, and interruptions due to aggregate length and complexity of an interconnected system of conductors must be met by improvement in automatic circuit-breaking devices, arranged with reference to the location of interruptions of service due to failure of insulation or

RUBBER INSULATED, STEEL ARMOURED, SINGLE-CONDUCTOR CABLE FOR SUBMARINE WORK, AS USED BY THE INTERBOROUGH RAPID TRANSIT CO., OF NEW YORK

CROSS SECTION OF A CABLE MANHOLE OF THE MANHATTAN DIVISION OF THE INTER-BOROUGH RAPID TRANSIT COMPANY, OF NEW YORK

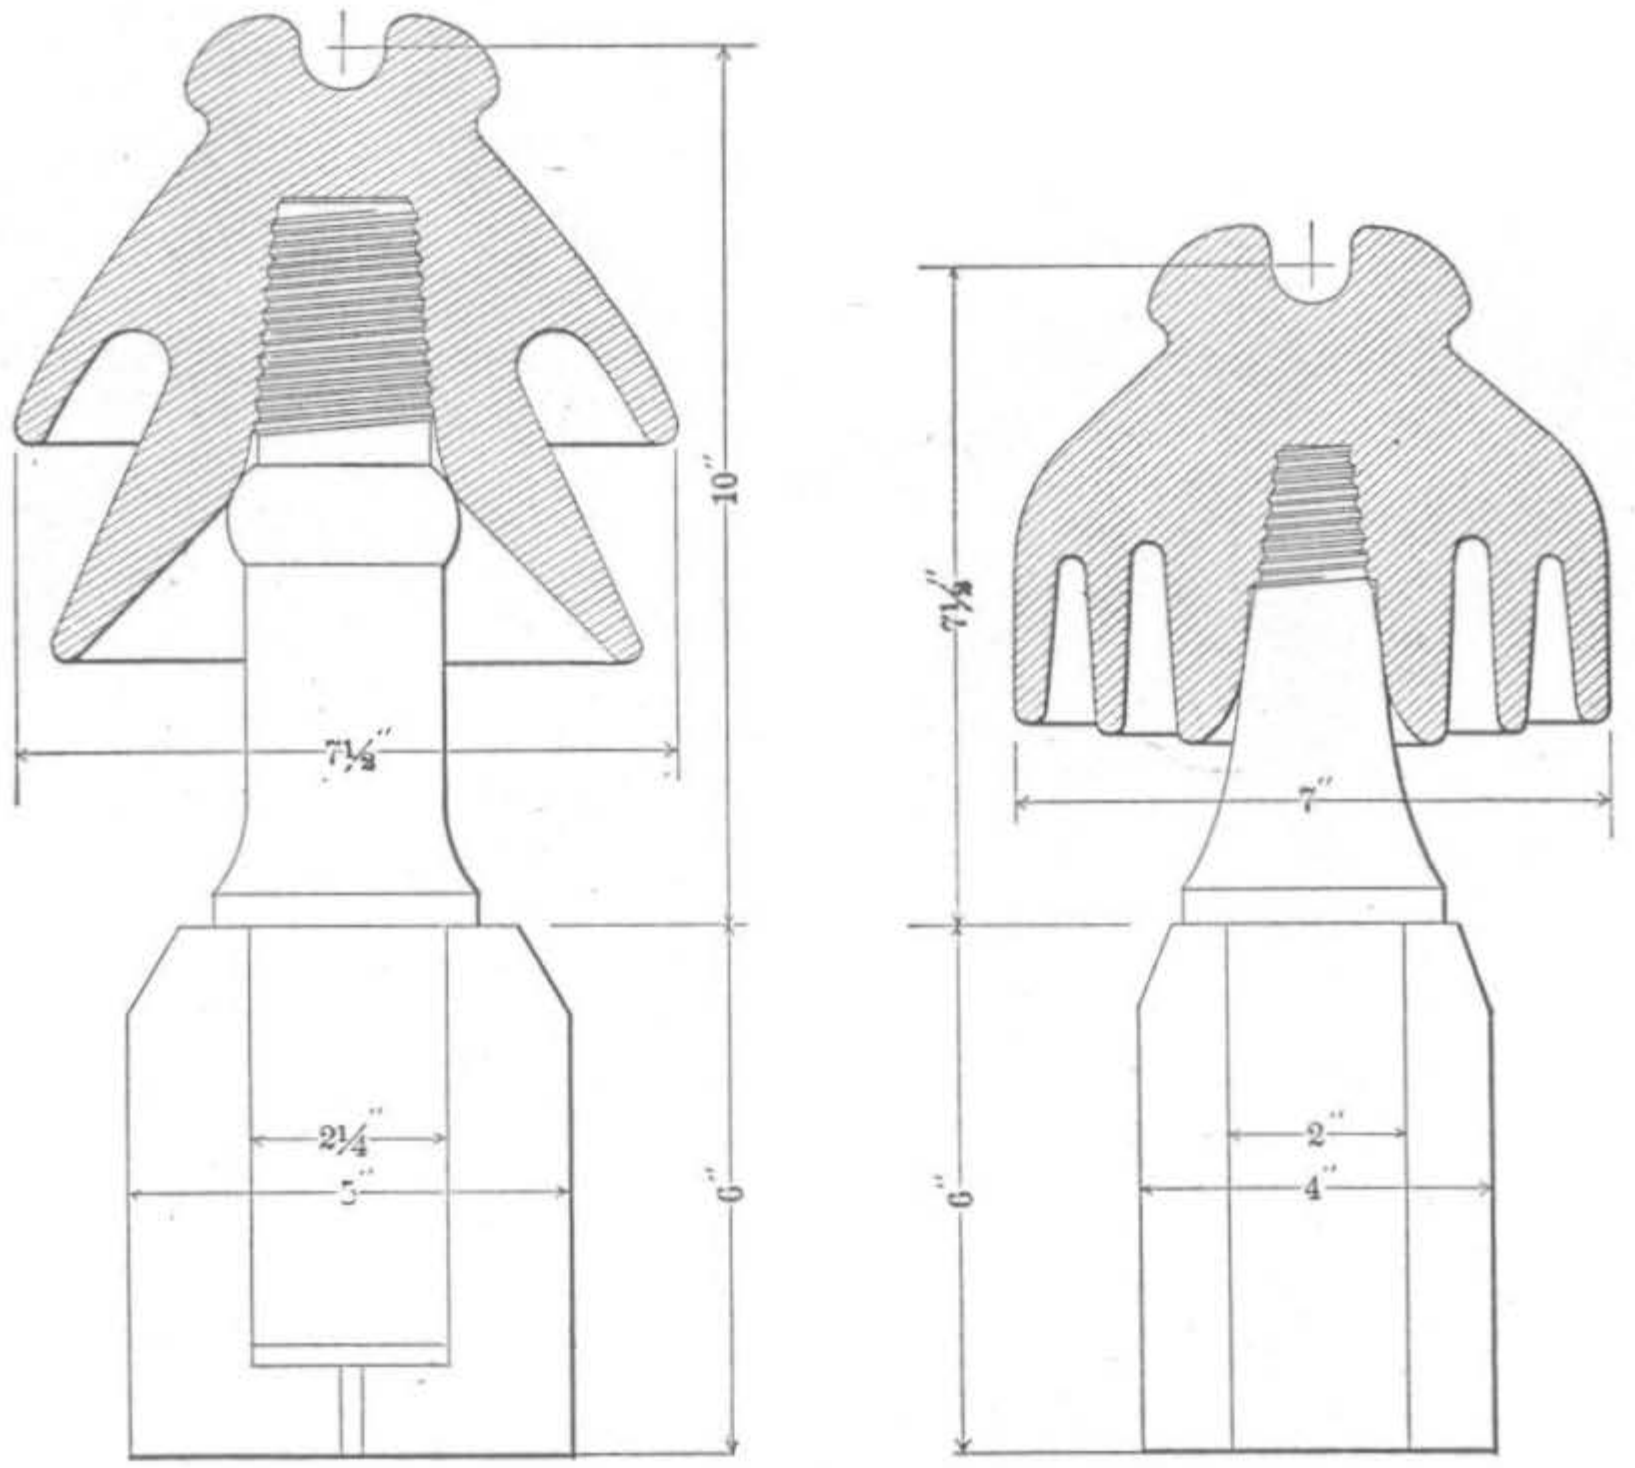
other causes. The fact that during the past ten years the rate of interest upon capital has been decreasing in America has, doubtless, tended to lessen in some degree the force of the argument in favour of a rapid increase in potentials adopted for new plants; but the reasoning which is brought to bear upon such questions as the selection of potential too often has little connection, or at least little conscious connection, with such matters as a progressive fall in rates of interest.

A subject that has received less attention than it deserves is the difficulty of maintaining an uninterrupted supply of power to the motors, lamps, and other translating devices used by customers which results from increased lengths of conductors and increased numbers of translating devices connected to a single source of supply. Electrical engineers are not accustomed to enlarge upon the subject of interruptions of service, but the first step in the correction of defects is recognition of their existence, and reference to this phase of the general subject may be useful.

Obviously, interruptions of service may have their origin in the power plant, in the transmitting circuits, or in apparatus located upon the premises of the user. Other things being equal, those due to line troubles will vary with the length of the line, as has been clearly recognised since the earliest days of transmission. Equally obvious, but apparently less clearly recognised, is the fact that a plant delivering power to a dozen users over a line of equal length faces an increased risk of interruption of service by reason of the addi-

tion of a number of branch circuits at the receiving end of the line, and connection to the system of a dozen outfits of apparatus in users' premises in place of one. Where it happens necessarily, as at Buffalo, at Milan, and at a few other places, that a very considerable number of users are supplied through cables placed underground, which cables, in turn, receive through transforming stations their supply from overhead transmitting circuits extending across country from the water-power, the difficulties in the way of maintaining an uninterrupted supply of power become very serious.

Imagine, if you please, that in a given city a score of separate steam engines are used to drive line shafts in twenty factories and mills. Each of these engines is liable to a certain number of accidental interruptions of service, averaging, perhaps, one per annum. If, for the twenty steam plants, twenty electric motors, supplied through an inter-connected system of conductors, be substituted, it is evident that effective means must be adopted to prevent an accident to one motor, resulting in interruption of service in the twenty factories and mills; otherwise if accidents causing interruption average the same with motors as with steam plants, each user will suffer from twenty interruptions per annum instead of from one.



It may be noted still further that the user who philosophically bears with an interruption caused by apparatus owned by himself is usually far from philosophical when inconvenienced by interruptions of service due primarily to failure of other people's machinery. The reasons for adopting effective means for preventing interruptions of service, therefore, increase in a ratio greater than the increase in number of users.

Unfortunately, the complete solution of the problem cannot be found in the adoption of the fuse or safety-link, which is generally and satisfactorily used in dealing with the similar problem which arises in supplying lamps and motors connected to the great direct-current networks in the large cities, since in such cases as that of Buffalo the distances involved in the local distribution are so great as to make the use of high-potential circuits to more than one transforming station imperative, and with circuits conveying alternating currents at 10,000 volts or even at 2000 volts ordinary fuse strips are altogether inapplicable, while nine-tenths of the special devices which have been proposed to take their place are equally useless.

The problem is made still more difficult by the phenomena of resonance and so-called electric surging, the latter of which always follows a sudden disturbance of potential of the system, while the former, under certain conditions of capacity, inductance, and frequency, is liable to develop potentials capable of breaking down the most perfect insulation available at the present time. Obviously here is a fine opportunity for the exercise of skill, sound judgment, and perhaps even inventive ability upon the part of the engineer who lays out a system of high-potential alternating-current distribution destined to supply power at some future time, if not at the outstart, to a large number of users distributed over territory too extensive to be reached by direct current.

The first thing to be done is, of course, to secure throughout the system the most perfect insulation that is practicable. Could the insulation be maintained perfect in all parts, nothing more would be needed. This, unfortunately, is not the case, and it becomes necessary, therefore, to lay out such a system of distribution with the greatest possible care, adopting effective means for localising the interruption which can result from a failure of insulation in any part of the system.

Much has been done since 1893 to overcome the difficulties faced by the companies which first ventured into the field of polyphase transmission and distribution, but there is still room for material improvement. The insulation of cables has made wonderful progress, as have also glass and porcelain insulators for overhead lines, although the quality of American porcelain is not yet equal

TYPE C AND TYPE E INSULATORS USED BY THE NIAGARA FALLS POWER COMPANY

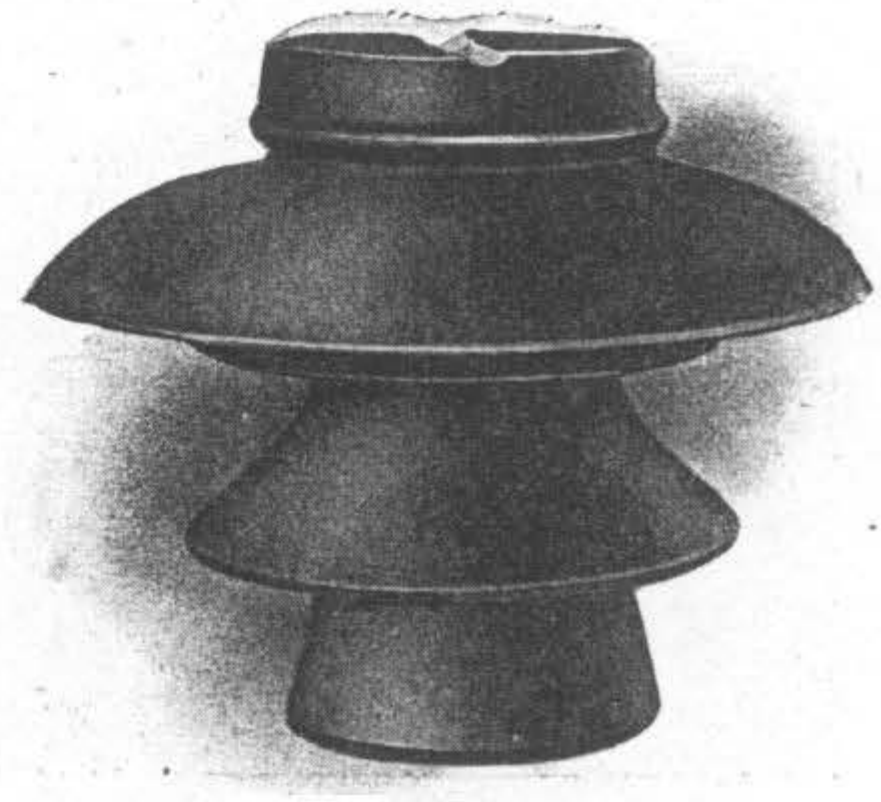
to that of European porcelain used for the same purpose.

The time-limit circuit-breaker, intelligently applied, is of great value in lessening the evil consequence of failure of insulation by localising the resultant interruption of service; but the reversed current circuit-breaker, first used by Andrews, at Hastings, England, which should be an equally valuable adjunct to a transmission plant, is not yet available in thoroughly satisfactory form. The extraordinary development of the oil switch in recent years in America, following, but quickly surpassing, European practice, has furnished an effective solution to many of the vexing questions of switchboard practice which caused so much trouble a few years ago. The insulation of dynamos to-day is such that the generation of currents at 11,000 volts is effected with a factor of safety equal to what was possible ten years ago with generated potentials of 2200 volts, and the advance in construction of transformers is almost equally striking.

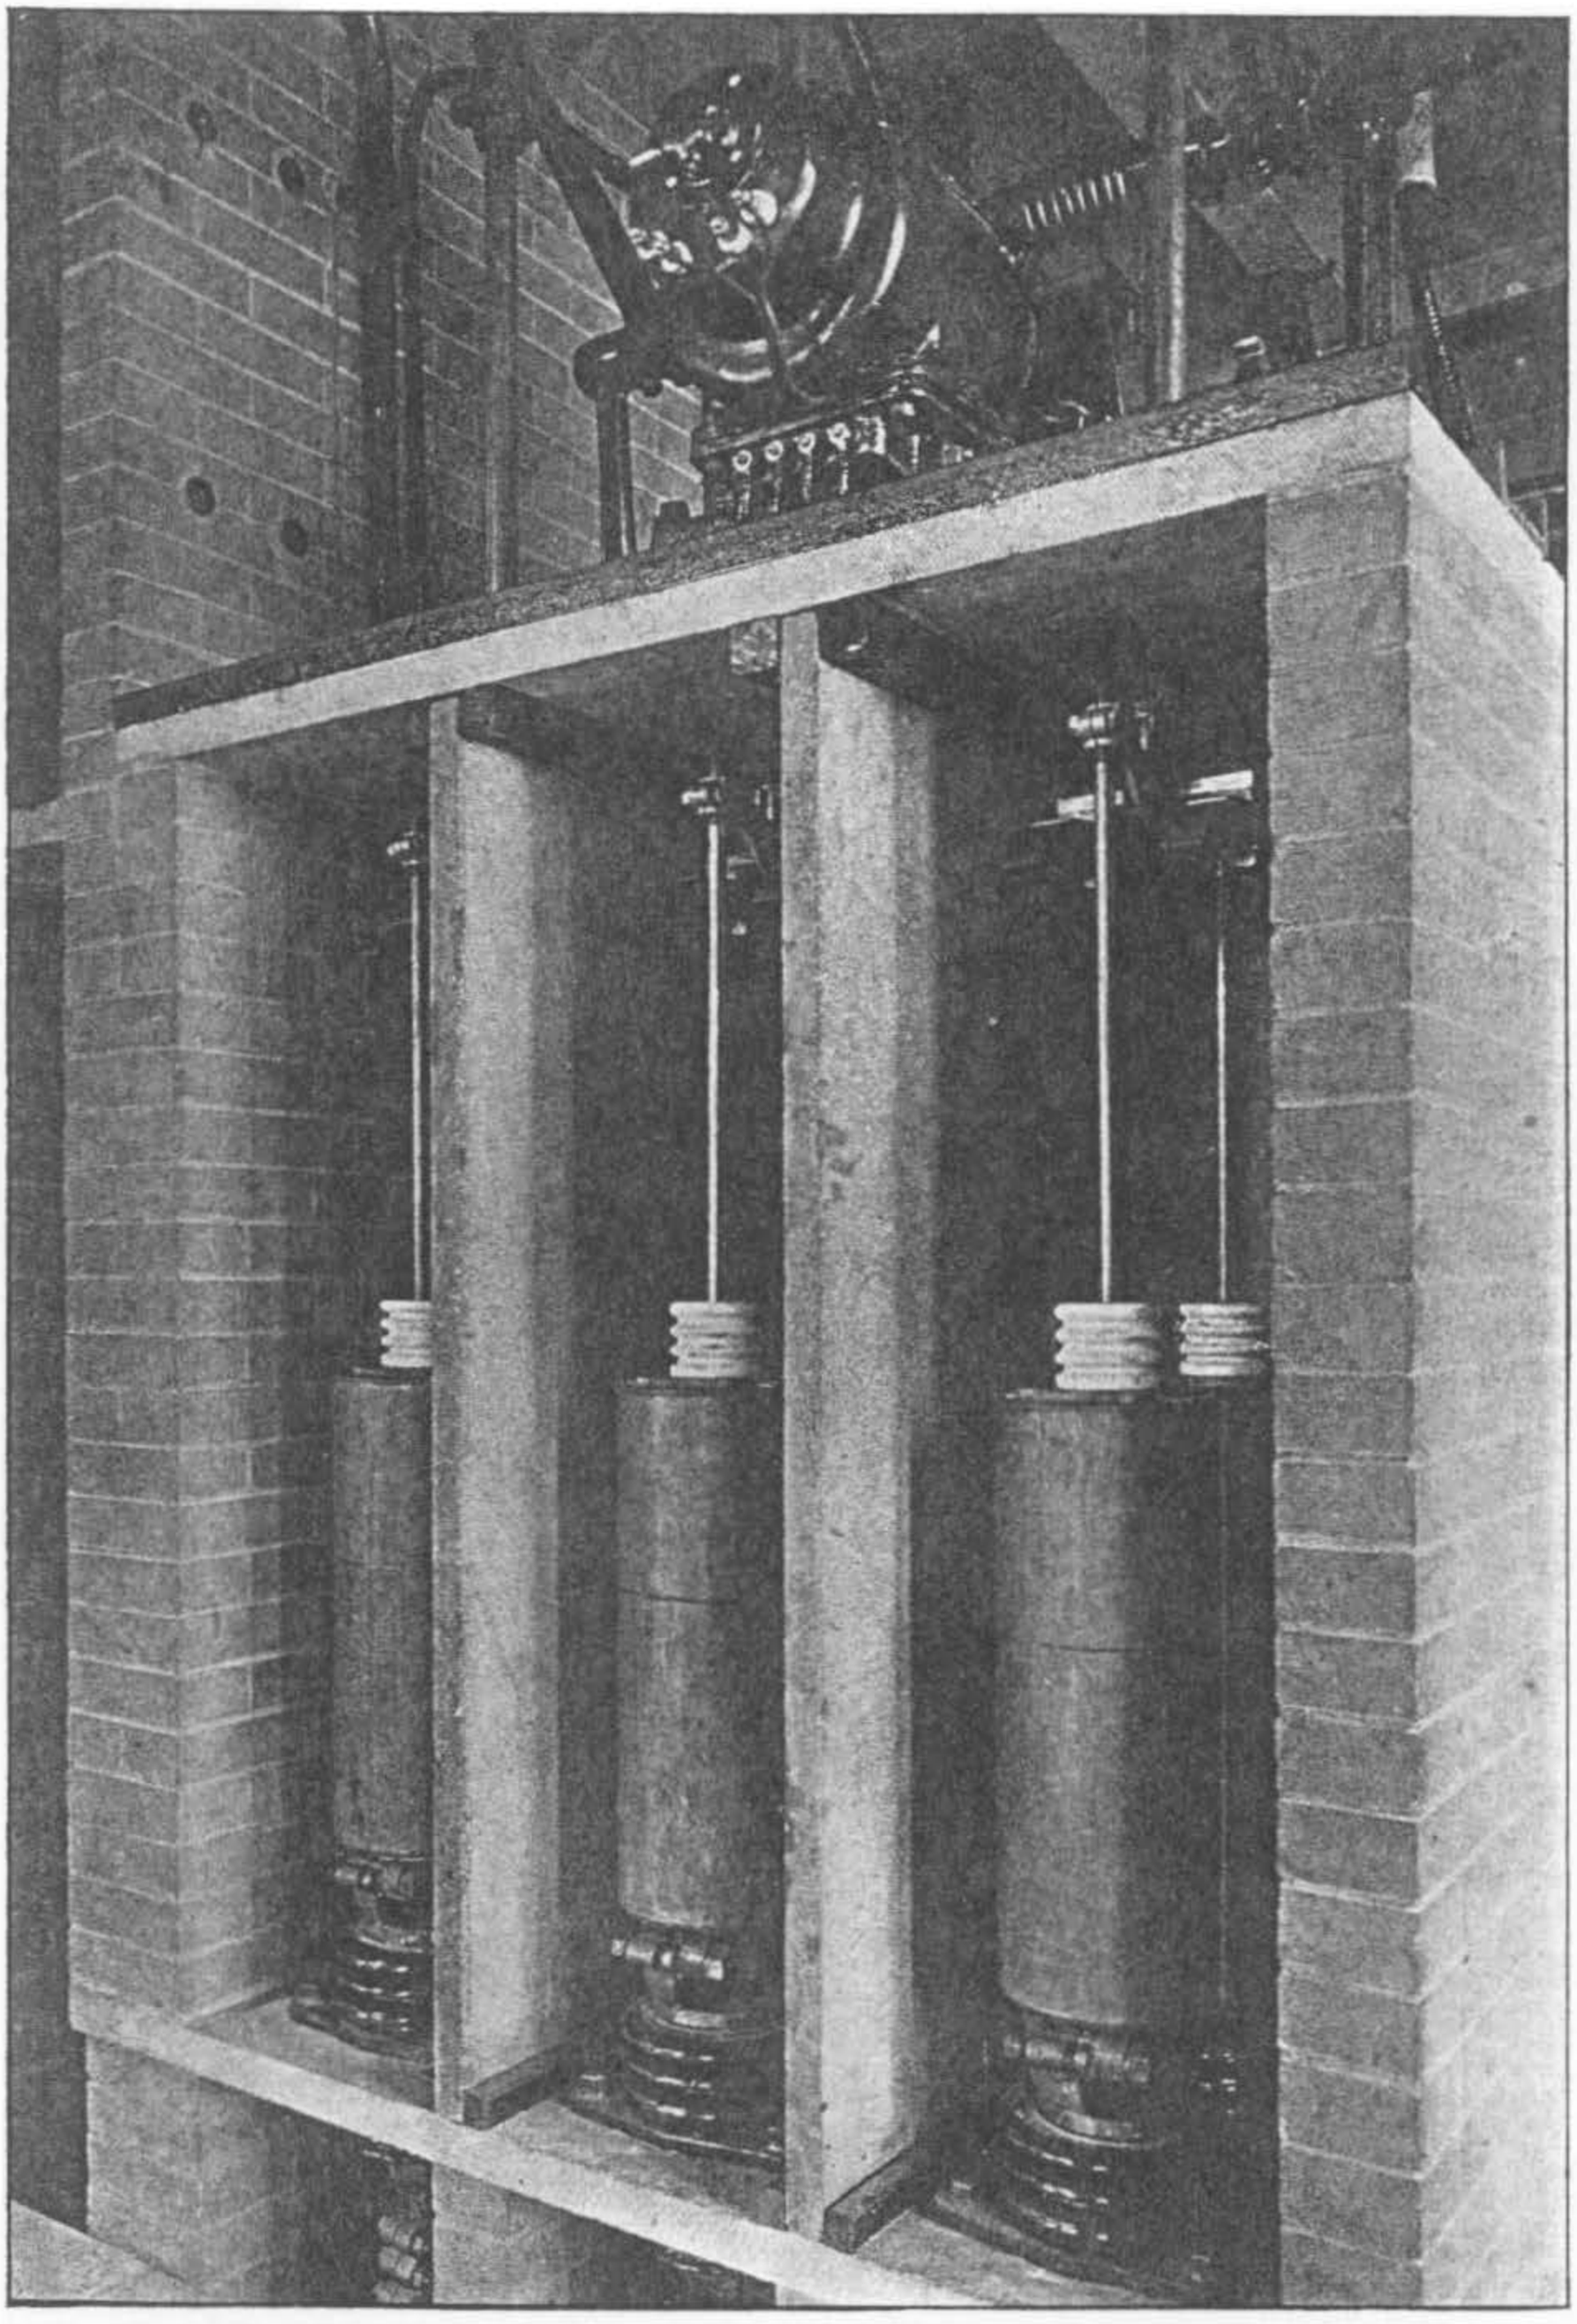
In large plants the general adoption of the method of operating switches in the power circuits at a distance from the operator by means of compressed air or electricity, insuring safety of the operator, has resulted in great gain in certainty of operation. To this end also have contributed a number of valuable auxiliary devices, such as the ingenious and effective synchronism indicator invented by Mr. Paul M. Lincoln, the diagrammatic arrangement of control switches, which places under the eye of the operator at all times an accurate diagram of connections existing throughout the system, various improvements in regulating and governing mechanism of engines, and more particularly of hydraulic turbines, and, most important of all, perhaps, the development of devices for the protection of electric apparatus against the effects of atmospheric electricity.

It may be interesting to refer briefly to some of the more important of these improvements of the last decade. As

regards means available for transmission, the most striking development is the rapid evolution of cables insulated by paper, treated with resinous oils.



They are necessarily lead-sheathed to protect the insulation against moisture, and if the sheath be preserved and the cables be not operated at temperatures exceeding 80 C. degrees, there appears to be no reason to doubt their durability. In the city of New York, the Manhattan division of the Interborough Rapid Transit Company now has in use upwards of 120 miles of cable of this character, operating at a potential of 10,500 volts, and during the last nine months there have been only two failures of cable insulation, one of which, however, did not cause any interruption of service.



At St. Paul, Minnesota, the gas light company has, for the past four years, successfully operated cable of this kind under a potential exceeding 20,000 volts, and recently in developing plans for an important transmission project I have received from two reliable manufacturing companies quotations upon paper-insulated cables guaranteed for service under a potential of 33,000 volts, alternating. There is no reason to doubt that cable of this type, constructed under proper specifications and with sufficient care may now be considered thoroughly reliable for commercial service under such potentials as these, provided proper precautions are observed in the arrangement of circuits and in the installation of protective devices to prevent such cables being subjected for any appreciable length of time to potentials materially exceeding the working potentials for which they are intended. The illustration on page 102 shows the construction of three-conductor cable as used by the Interborough Rapid Transit Company for 11,000-volt, three-phase distribution in ducts.

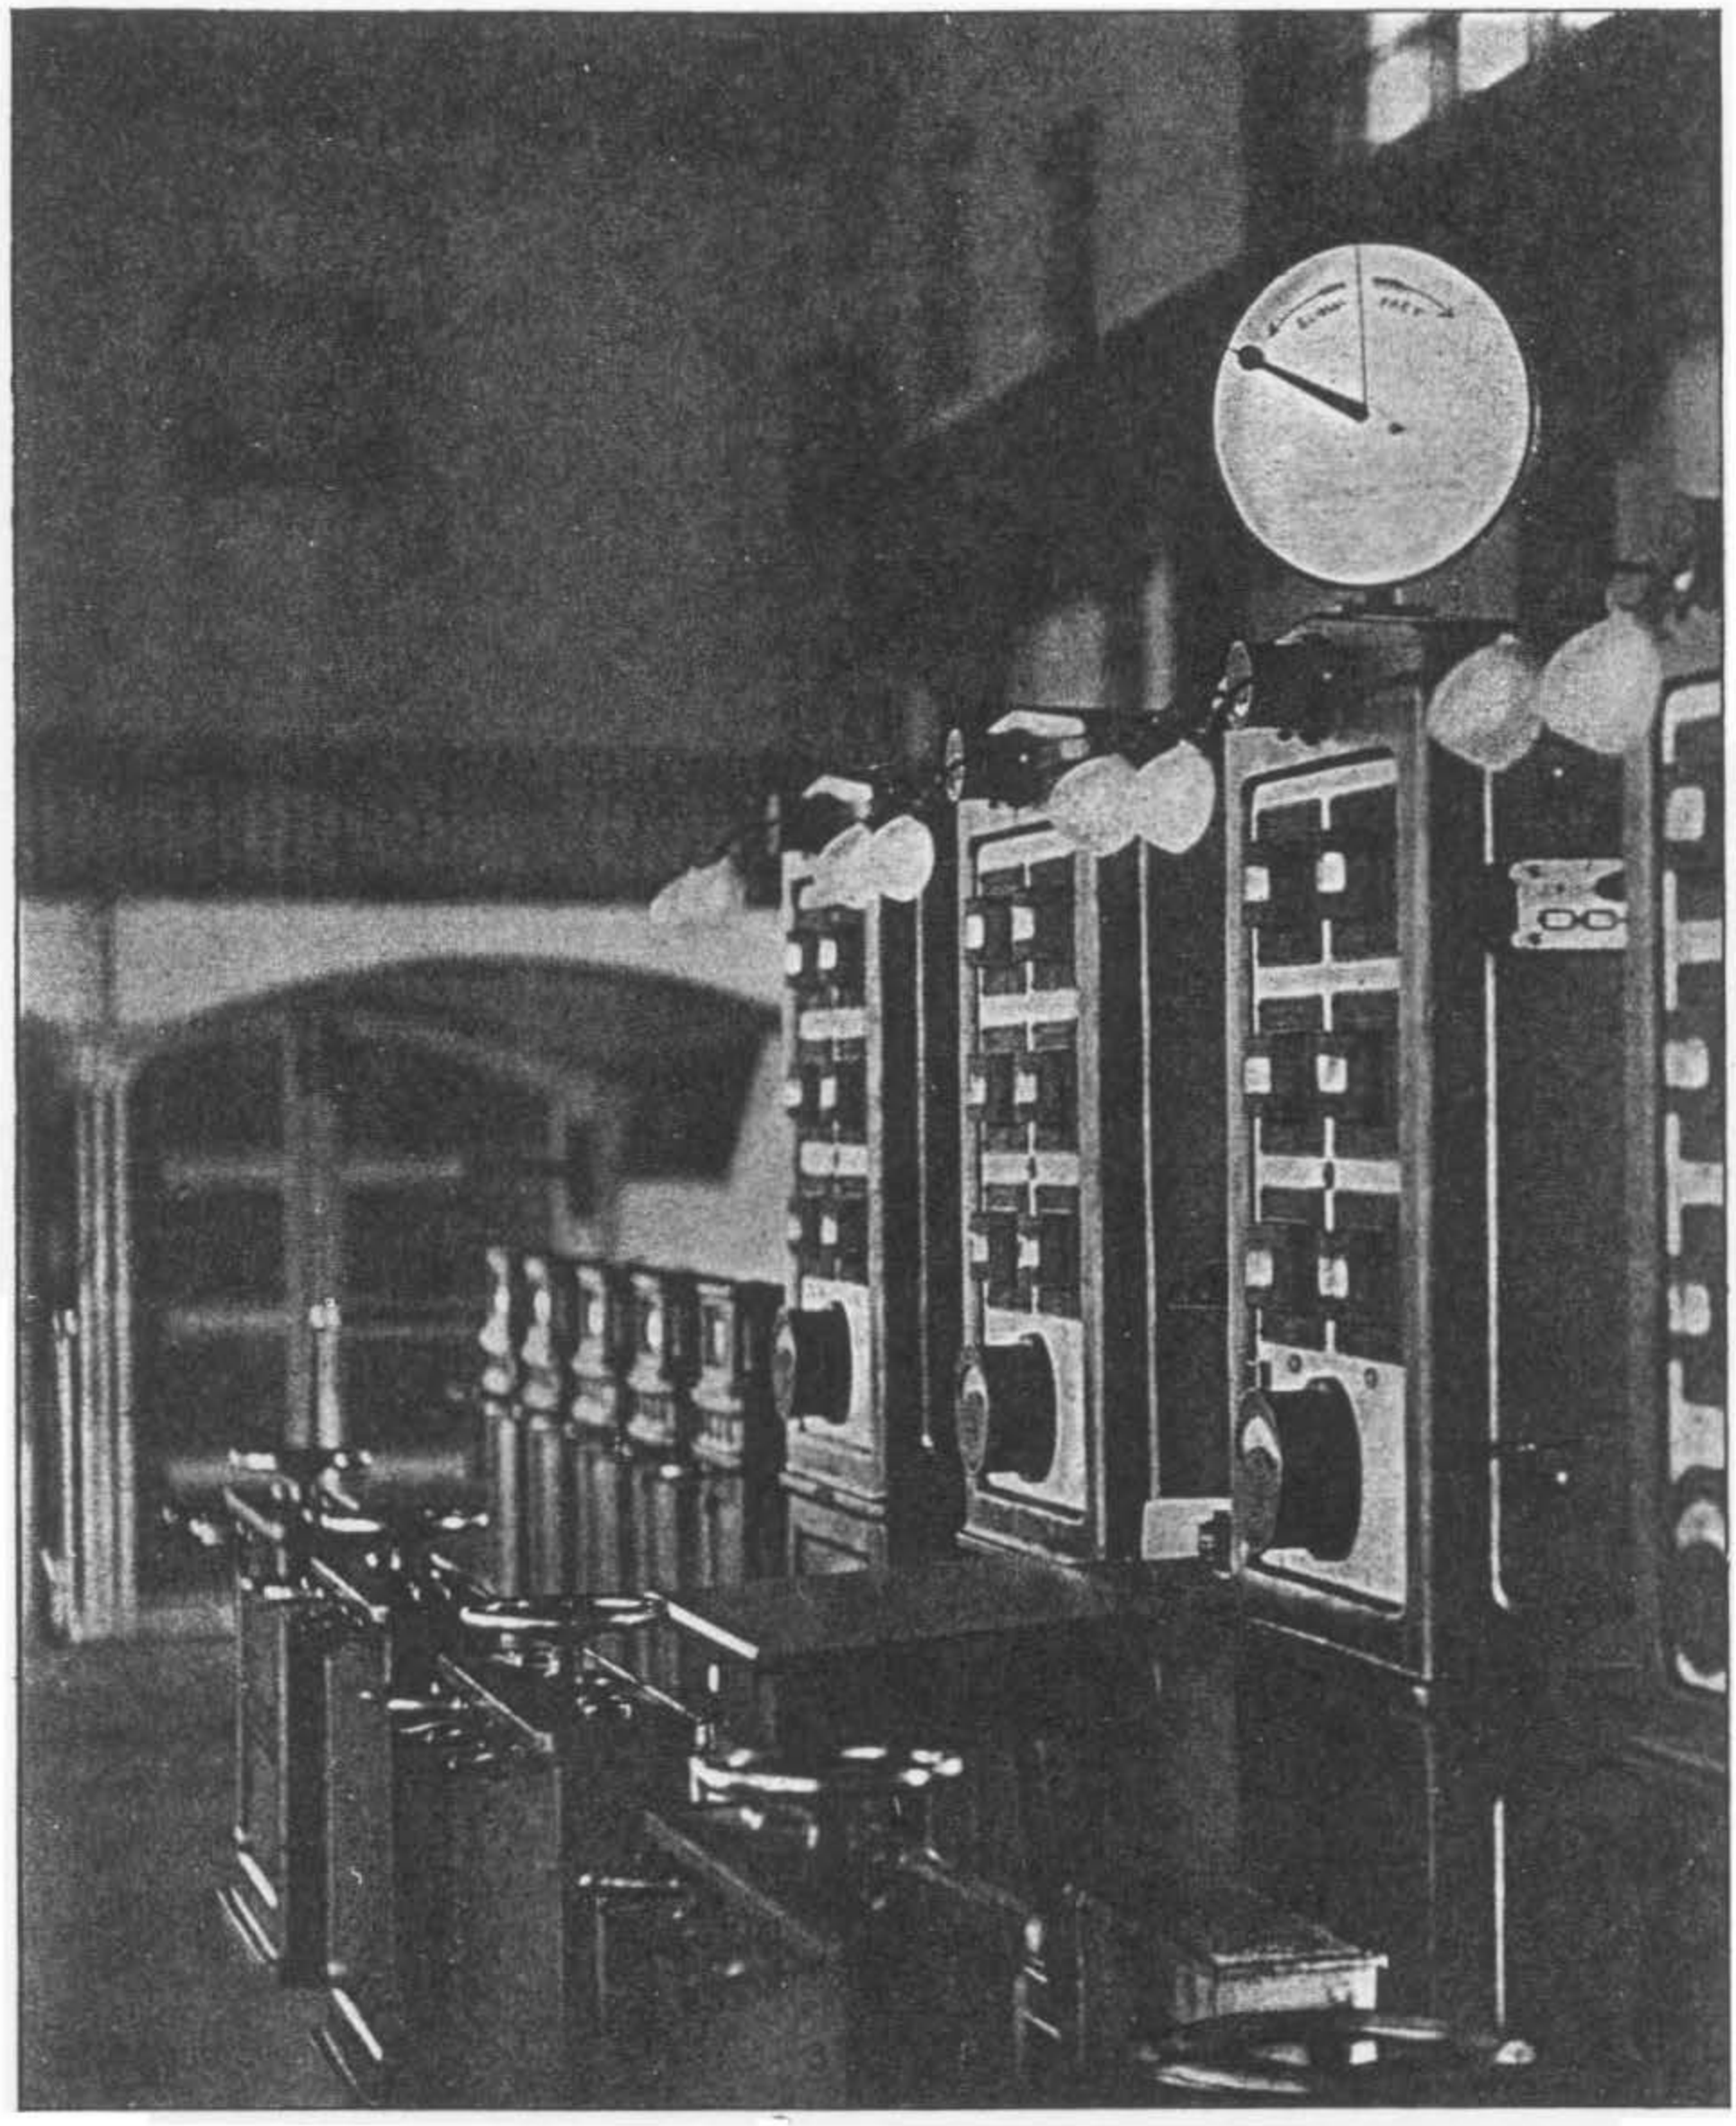
The illustrations on pages 103 and 105 show, respectively, cross sections of three-conductor, rubber-insulated, steel armoured cable and single-conductor, rubber-insulated, steel-armoured cable, as used by the same company in submarine work.

Methods of laying cables also have greatly im-

PORCELAIN INSULATORS FOR HIGH-POTENTIAL CIRCUITS

A MOTOR-OPERATED OIL SWITCH FOR 11,000-VOLT THREE-PHASE CIRCUITS, MADE BY THE GENERAL ELECTRIC COMPANY, SCHENECTADY, NEW YORK

proved. In the United States they are now usually laid in tile ducts, set in concrete. Much of this duct work is still badly done, particularly with reference to the dissipation of heat, due to currents traversing the cables; but general practice in this respect has improved greatly within the last two or three years. The illustrations on pages 104 and 106 show, respectively, a cross-section of a cable conduit and a cross-section of a manhole as used by the Manhattan division of the Interborough Rapid Transit Company.



Insulators for overhead lines have been very radically improved since 1893. The insulator used in the Frankfort-Lauffen transmission employed an oil cup to decrease surface leakage. Dust and other material, accumulating upon the surface of the oil, destroy its insulating value, and this type of insulator is, therefore, not now used commercially. The 10,000-volt plant at Pomona and San Bernardino, California, installed in 1890 and still in successful operation, uses a double-petticoat glass insulator designed by Morris, of the Westinghouse Company, and the writer, and in 1895 this insulator was successfully used by Mershon during the high-potential tests which he conducted at Telluride, Colorado, under a potential of 45,000 volts.

The so-called "Type C" insulator, as used by the Niagara Falls Power Company upon the first pole line, erected between the Falls and Buffalo, and the "Type E" insulator, as used upon the second pole line, erected in 1900, are shown in section on page 108. The former was particularly defective in respect to its mechanical attachment to the pin, which was but ⅞ inch in diameter at the top, while the number of screw threads engaging pin with insulator was but six. The pin used with the "Type E" insulator is 1½ inches in diameter at the top, and nine threads secure the insulator to the pin. The Niagara Falls Power Company increased the line potential between Niagara and Buffalo from 11,000 volts to 22,000 volts in the spring of 1901, and since that time has been replacing gradually the "Type C" insulators on the old line by insulators of the newer type, which have been very successful.

On page 109 are shown illustrations of three insulators. The smallest is "Type E," as now used at Niagara, while the largest is an insulator made by the Locke Insulator Manufacturing Company, of Victor, New York, for very high voltage. This insulator has been selected for the 101-mile transmission plant of the Guanajuato Power & Electric Company, in Mexico, which company is now using successfully a potential of 60,000 volts. The insulator of intermediate size is one which the writer designed several years ago for line potentials of from 40,000 to 50,000 volts. It is the largest porcelain insulator made in a single piece, the Locke insulator being made in several concentric materials or cups which are cemented together. Many other insulators effective for line potentials up to 50,000 volts are now available, and some of the more recent of these are designed for pins of adequate size.

Probably the most valuable single addition to apparatus developed since 1893 for high-potential transmission is the electrically-operated oil switch. The illustration on page 110 gives an excellent idea of its construction, as built by the General Electric Company, of Schenectady, New York, for 11,000 volt, three-phase circuits.

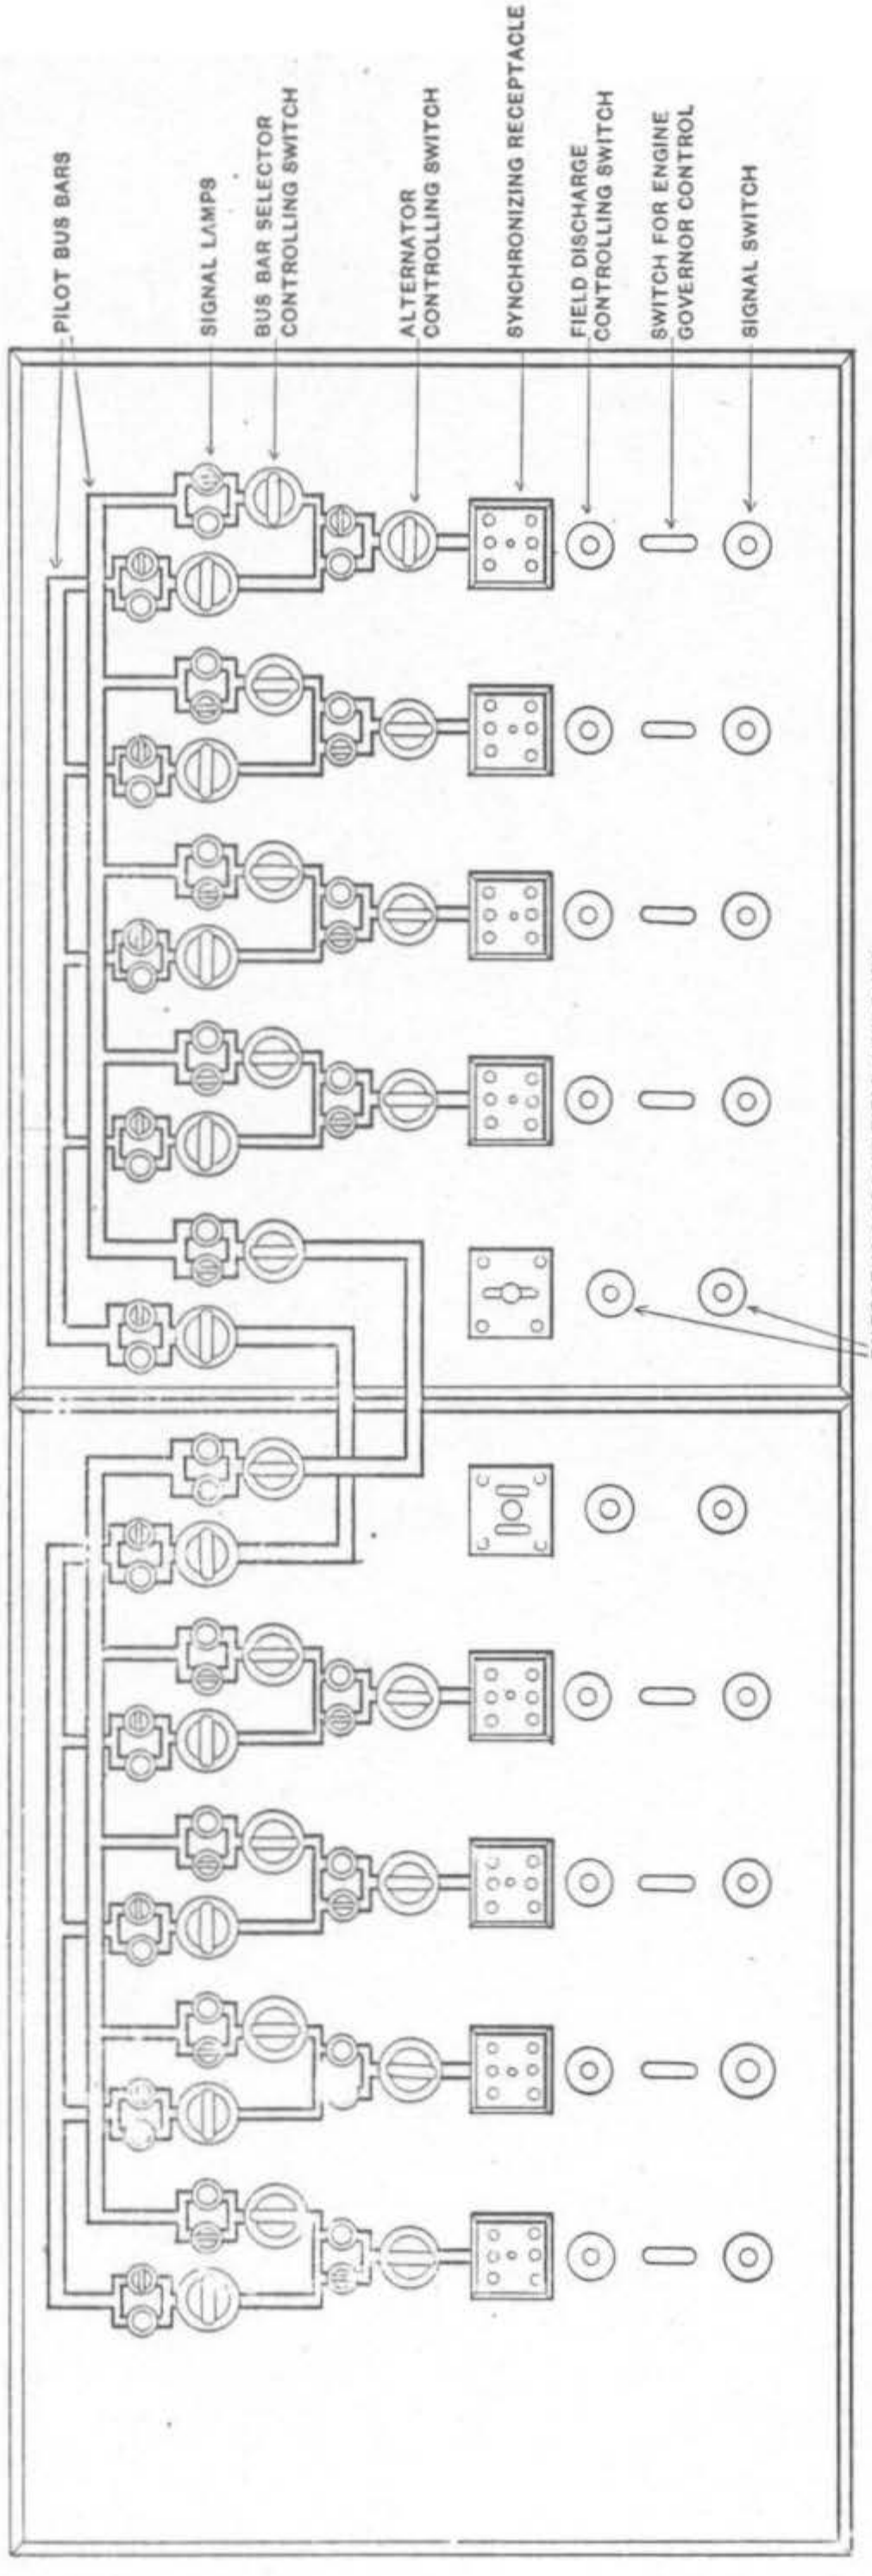
Two breaks are provided for each of the three sides of the circuit, and in opening the circuit the break is made under oil contained in large metal cylinders. Each cylinder contains a fixed terminal. When the switch is closed, current passes from one terminal of each pair to the other through two vertical rods of copper connected at their upper ends. The switch parts belonging to each of the three sides of the circuit are separated from all other parts of the switch and its mechanism by being enclosed in a brick compartment with vertical partitions of soapstone, as shown in the illustration. The moving parts of the switch are operated by mechanism located upon the top of the brick compartment, this mechanism being, in turn, actuated by an

LINCOLN SYNCHRONISM INDICATOR AS USED BY THE NIAGARA FALLS POWER COMPANY

electric motor which is controlled by circuits extending from the control board, or pilot board as it is sometimes called. At the control board the operator has before him a small switch, sometimes two, corresponding to each of the large three-phase switches, and the movements of the latter are controlled by opening and closing the former.

The plan of opening and closing switches located at a distance from the operator by compressed air or electricity was first adopted, I believe, by the Westinghouse Company in connection with the switch gear installed in the first power house of the Niagara Falls Power Company. In that plant the plan demonstrated its value, and it is now generally and in fact almost necessarily

adopted in the case of all large modern plants. The sense of security enjoyed by the operator while controlling these great switches at a distance results in confidence which goes far to ensure that precision which is so absolutely essential.



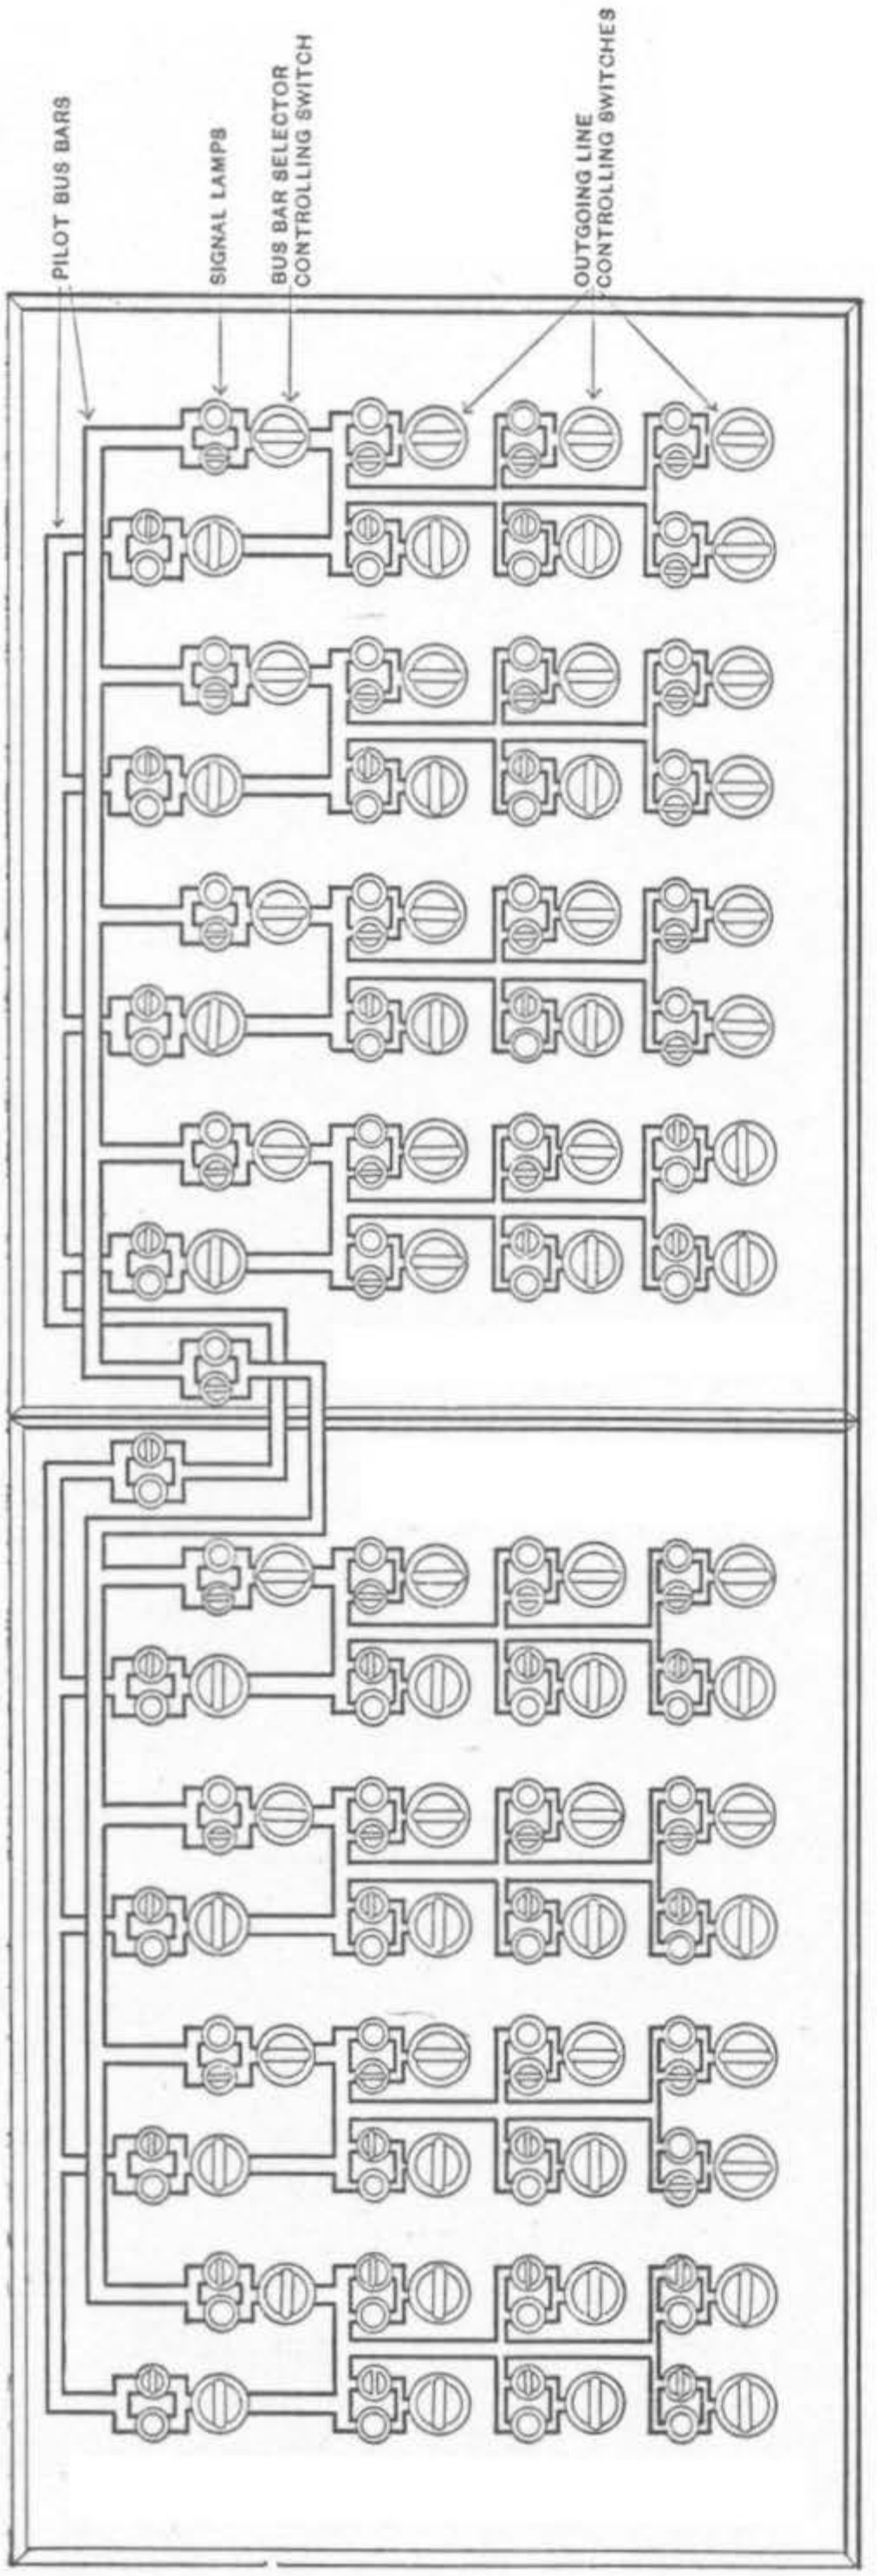
At the Manhattan Railway power plant in New York City sixty-six switches of this type are installed, and, on the average, have been in use about eighteen months. During that time not one of these switches has failed to operate as and when expected, and while some of them have been called upon to open automatically circuits in which extremely heavy short-circuited currents were flowing, they have done this without damage other than some spilling of oil from the oil cups.

The illustration on page 112 shows a synchronism indicator as installed upon Switchboard No. 1 in Power House No. 1 at Niagara Falls. This synchronism indicator, invented by Mr. Paul M. Lincoln, is an ingenious and most useful adjunct to a power plant using alternators. When an alternator is to be connected in parallel to bus bars supplied by one or more alternators the synchronism indicator is connected to the circuits through suitable transformers and becomes a perfect guide to the operator. The index arm of the indicator revolves at a speed proportional to the difference in speed between the alternator to be synchronised and the alternators supplying the bus bars, and it shows also which of the two is running at the higher speed. As used at Niagara, it is of very large size, and is mounted upon a vertical shaft which makes it possible to turn the face of the instrument so that it becomes visible not only to the operator upon the switchboard who throws the switches, but also to the governor attendant upon the floor who is adjusting the speed of the alternator preliminary to the operation of synchronising.

Still another comparatively recent auxiliary of value in the operation of large plants is the diagrammatic pilot board illustrated on pages 114 and 115. In this arrangement of the operating switches which control the power switches at a distance, dummy bus bars and other apparent (but not real) connections are provided and assembled in connection with the operating switches in such a way as to place before the operator at all times a diagram of the existing connections of the power circuits. Every time he changes the position of the pilot or control switches he alters the diagram to conform to the resulting connections of the power circuits, the diagram as indicated to the eye by handles of the pilot switches being corroborated by red and green signal lamps, one or the other of which is lighted when the corresponding power switch reaches the end of its travel in the movement incident to opening or closing the circuit. The illustrations on pages 114 and 115 show the diagrammatic pilot board and the instrument board as used for controlling the operation of eight 5000-KW alternators at the Manhattan power plant.

The development of the oil switch, which is capable not only of reliably making and breaking circuits in ordinary operation of the plant, but also of opening circuits traversed by short-circuiting currents as a result of failure of insulation, opens the way to the effective use of the time-limit relay attachment and of the reverse current relay attachment for such switches used as automatic circuit-breakers. The respective functions of these two relay attachments can be described best by reference to the diagram on page 116.

This diagram shows the essential connections of power circuits in a power plant comprising five alternators and transmitting power to a sub-station through two cables or overhead circuits. To simplify the diagram, the arrangement shown is that required for a single-phase apparatus, and but one set of bus bars is shown in the power house and also in the sub-station. From the sub-station four circuits serve to distribute power at low potential. If no time-limit circuit-breakers be used, a heavy short-circuit upon one of the distributing circuits from the sub-station may result in opening not only the circuit-breaker or fuse located in the sub-station to cut off

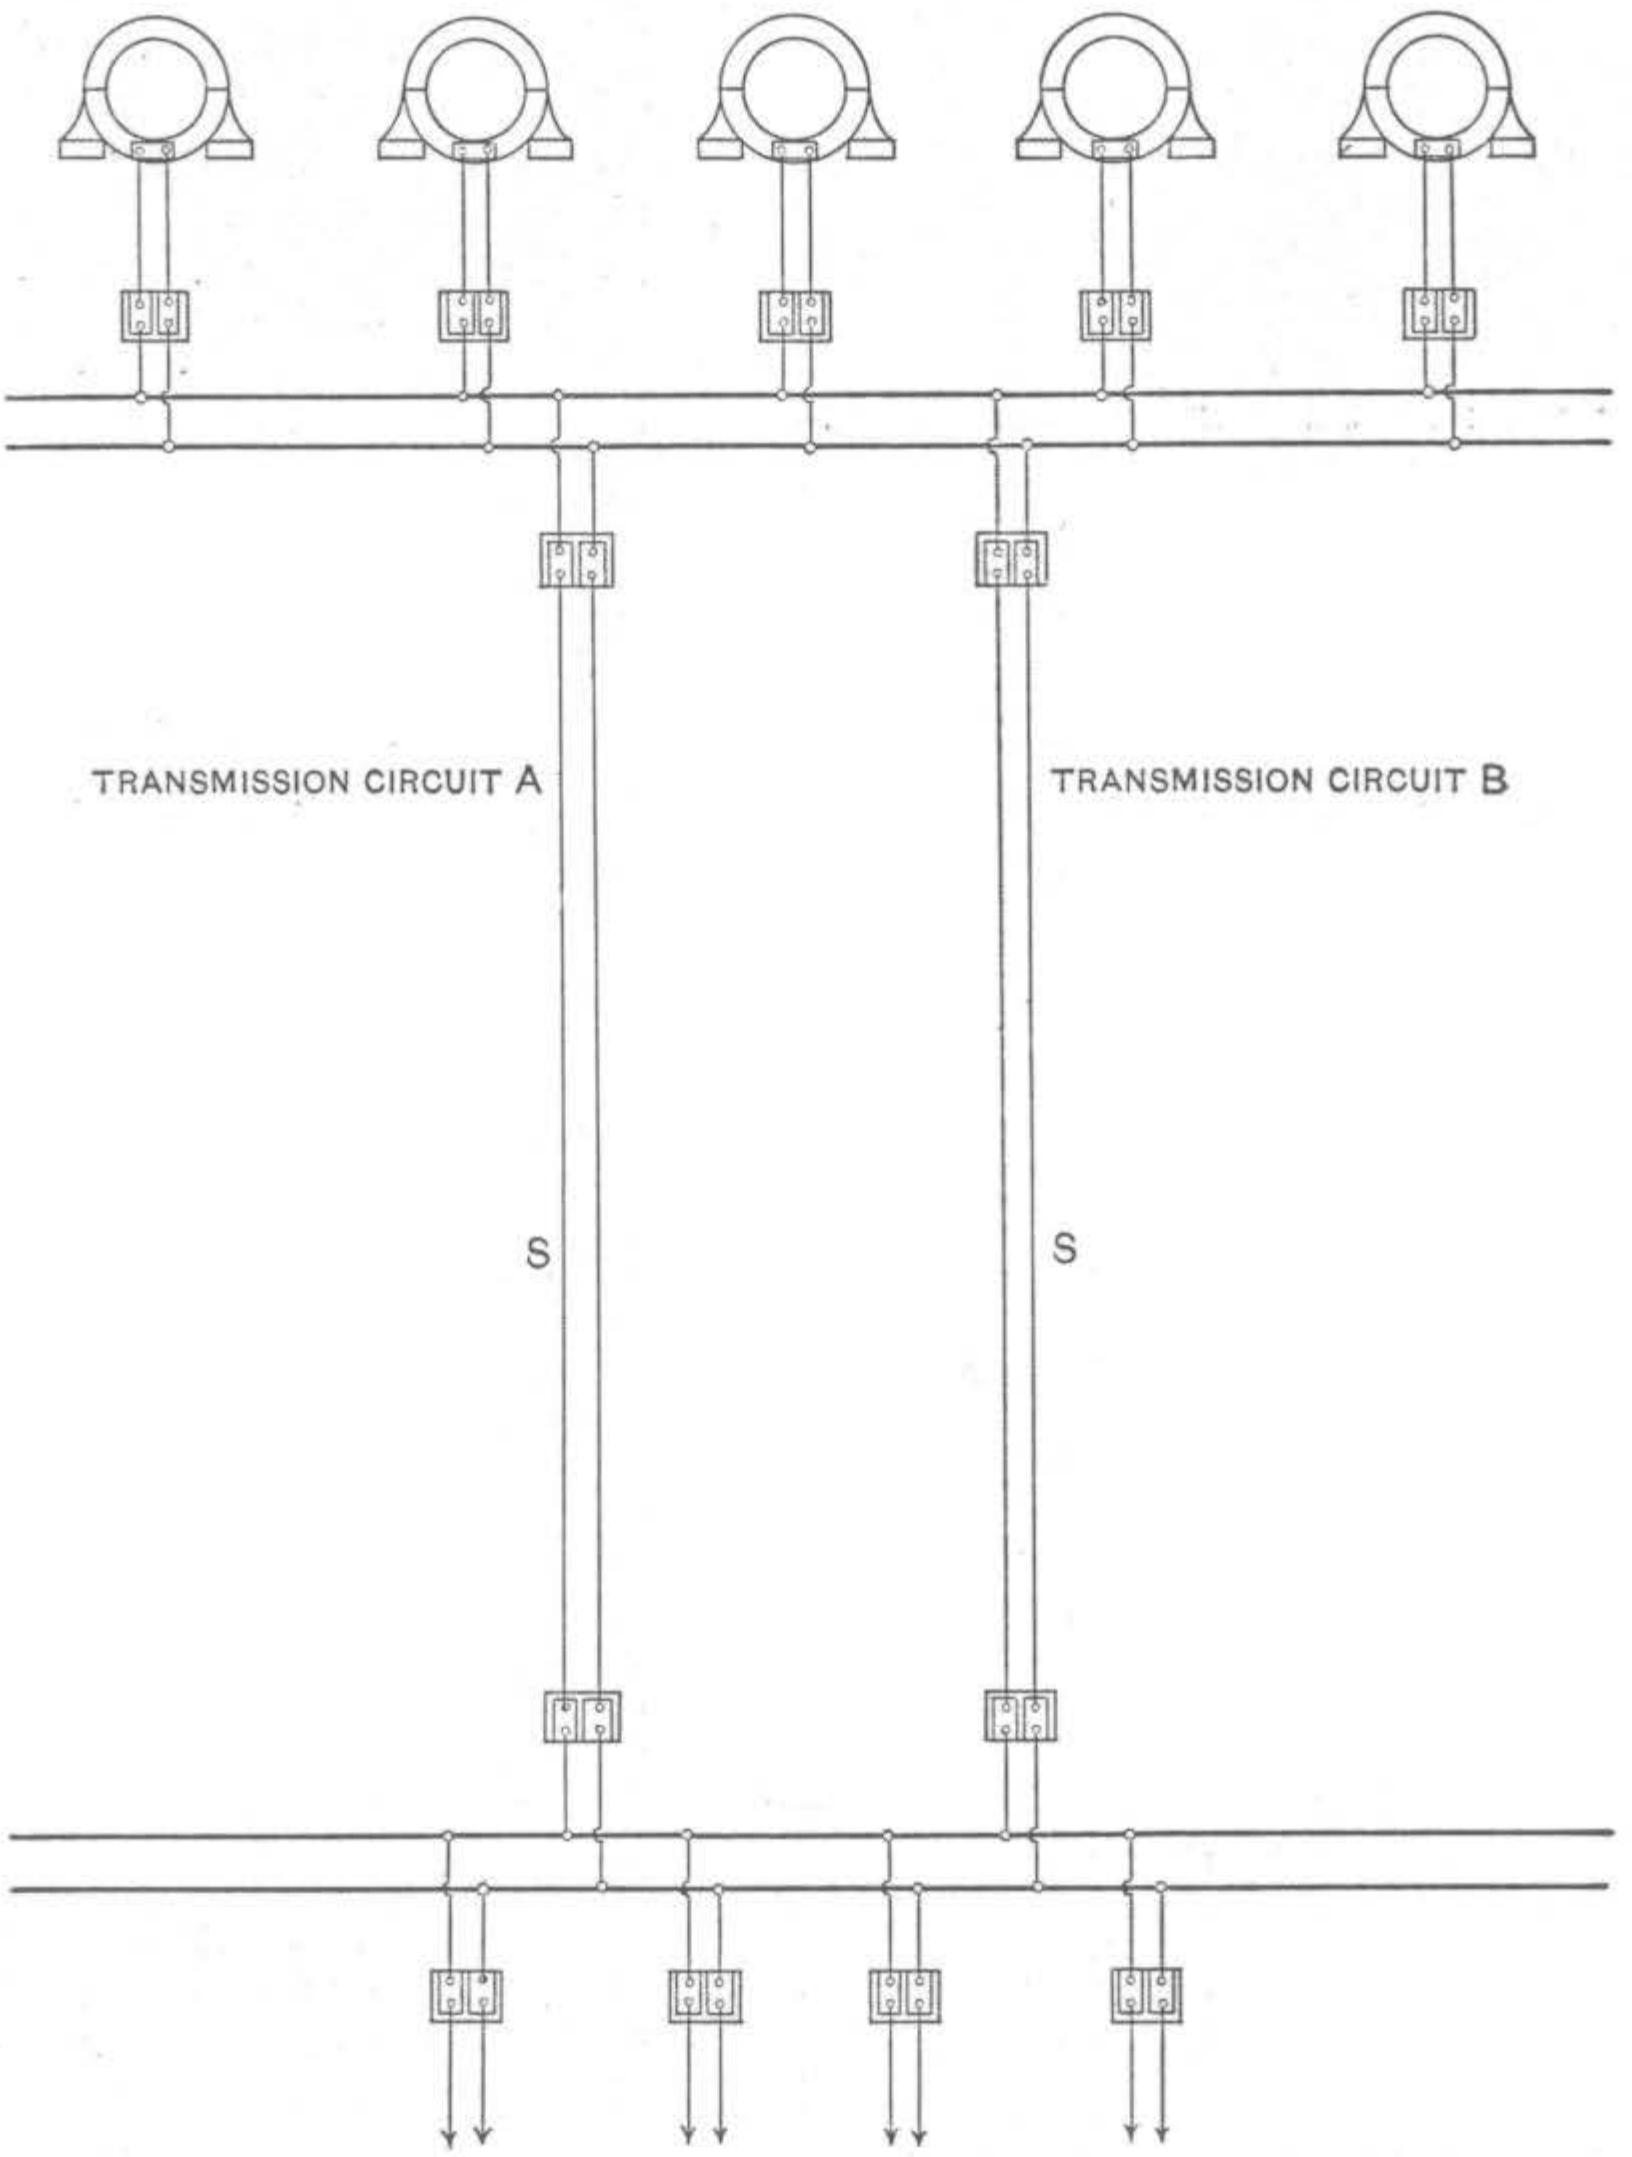


ALTERNATOR CONTROLLING BENCH BOARD USED BY THE MANHATTAN RAILWAY COMPANY, NEW YORK

the particular circuit affected, but also the circuit-breakers or other devices located at the power house and intended to cut off one or the other of the transmission circuits in case of a heavy short-circuit between power house and sub-station.

Instances have been known where even the automatic circuit-opening devices between dynamos and bus-bars have been opened as a result of a short-circuit beyond the transformers in the sub-station. If the time-limit relay be used in connection with the circuit-breakers, and if it be set, say, for three seconds in the case of circuit-breakers between dynamos and bus-bars, one second in the case of circuit-breakers in the transmission circuits at the power house end of the line and for instantaneous operation in distributing circuits from sub-station, the circuit-breaker in the distributing circuits at the sub-station may be relied upon to open before those in the transmission circuit at the power house, and, of course, also before those in the dynamo circuits at the power house can open. The interruption of service, therefore, which results from failure of insulation in one of the distributing circuits from the sub-station will be limited to the supply of power through the particular distributing circuit affected.

The reversed current circuit-breaker, which should be an equally valuable adjunct to a transmission plant, unfortunately, as has been said, is not yet available in thoroughly satisfactory form. Andrews used it between alternators and bus-bars for the purpose of cutting out an alternator which might become short-circuited. It is equally applicable, of course, to alternating-current circuits between a power house and sub-station, provided the circuits are connected in multiple with each other at both ends of the line.



ALTERNATING CURRENT FEEDER CONTROLLING BENCH BOARD USED BY THE MANHATTAN RAILWAY COMPANY, NEW YORK

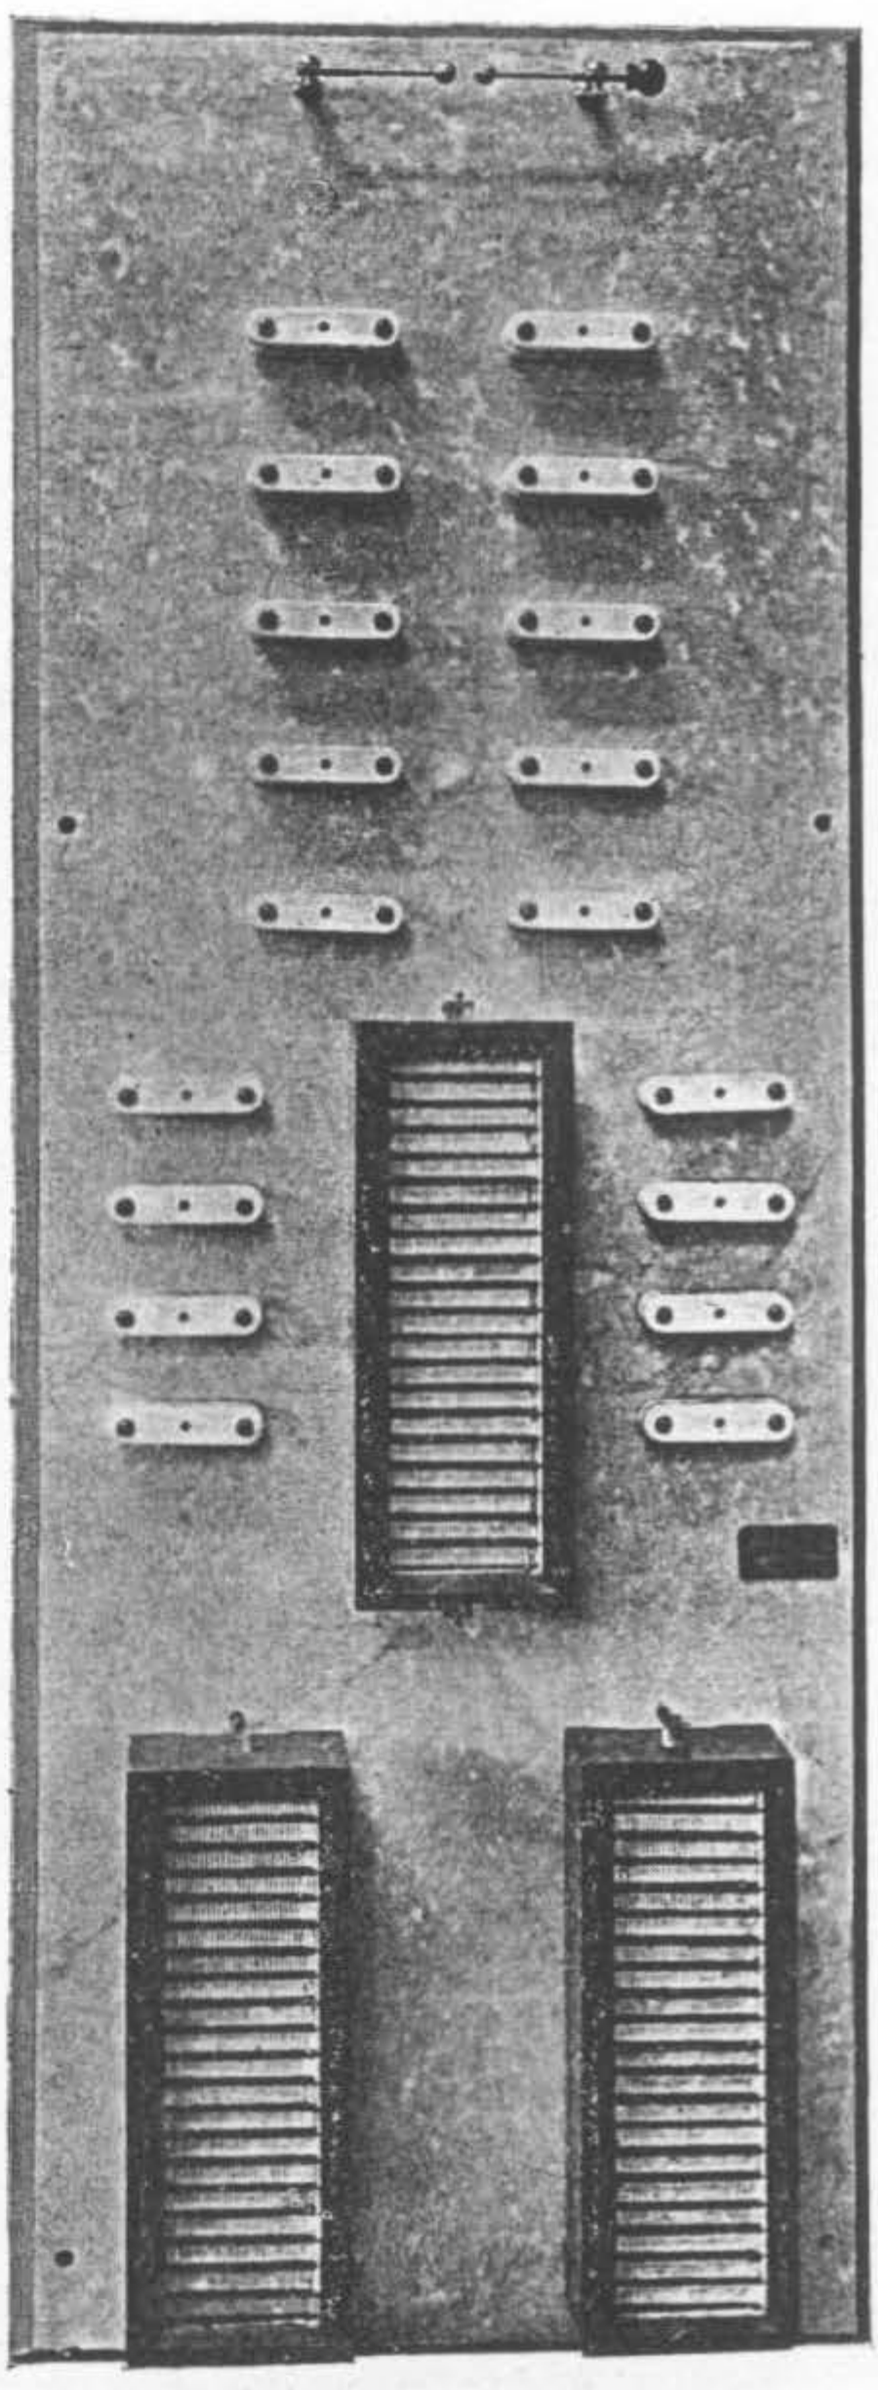
Referring again to the diagram on page 116, we may imagine that a short-circuit occurs on a transmission circuit, designated *A*, at the instant of maximum flow of current in one direction, which, for convenience, we may call positive. It is evident that the instant the insulation between conductors of circuit *A* is broken down, *e. g.*, at point designated *S*, current will flow from the bus-bars at the power house and also from bus-bars at the sub-station toward the point *S*. This implies a reversal in the direction of flow of current between the bus-bars at the sub-station and the point *S*, as compared with its direction at the given instant had no short-circuit occurred. This reversal may be utilised to open the circuit-breaker by actuating a relay device.

Practically all of the reversed current relays thus far tried in the United States have proved unsatisfactory by reason of the fact that they require a potential in phase with bus-bars at sub-stations, and in case of very heavy short-circuits this potential usually drops below the limit effective for operation. The required potential might be obtained from a small alternator, normally operated in synchronism with the power supply and equipped with a fly-wheel of sufficient size to keep the alternator going at synchronous speed for the necessary fraction of a second after the occurrence of the short-circuit, or perhaps better means might be devised for accomplishing the same purpose.

Where three or more circuits between power house and sub-station are available, reversed current relays can be operated by difference in current flowing through the short-circuited line and the other lines, and relays of this type are now upon the market.

Without entering further into discussion of details, it will be

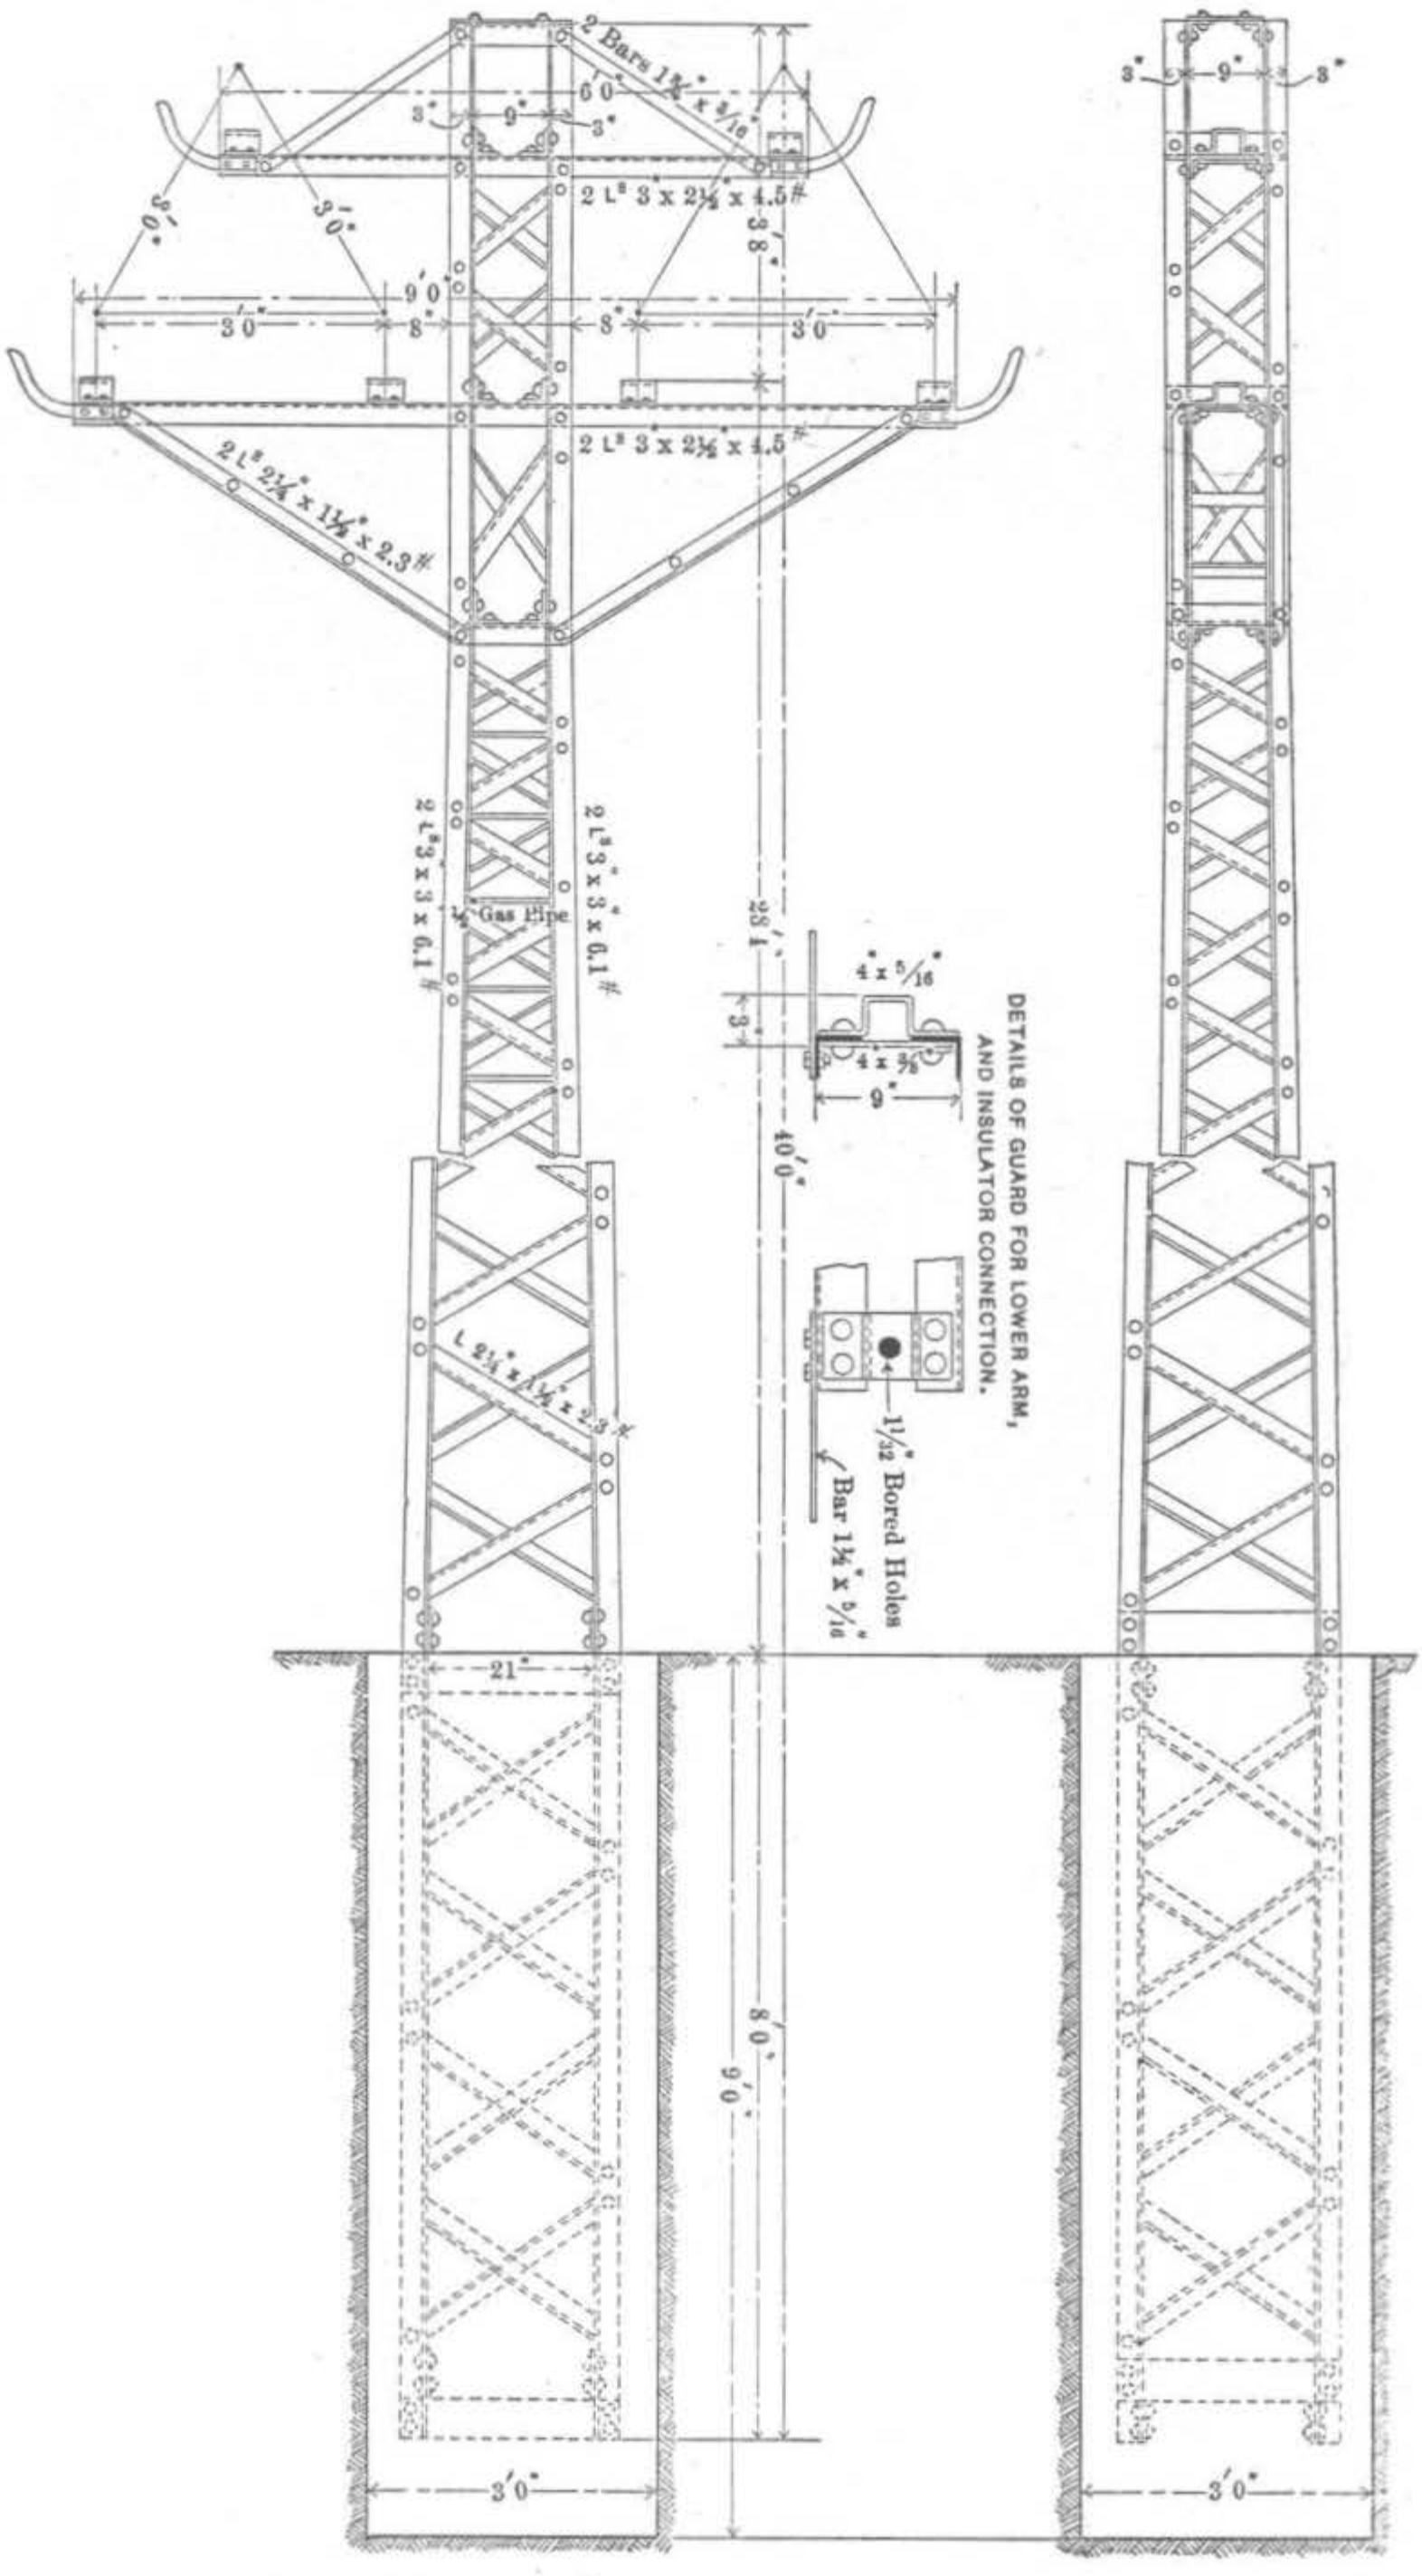
TYPICAL DIAGRAM ILLUSTRATING USE OF TIME LIMIT AND REVERSED CURRENT CIRCUIT BREAKERS



evident that proper use of the time-limit relay and of the reversed current relay, in combination with the oil switches now available, afford means for effectively localising the troubles resulting from any short-circuit in an interconnected alternating-current system of distribution which is carefully laid out with a view to such localisation.

Perhaps no adjunct of a successful transmission plant employing overhead circuits is more important than the lightning arrester, and in the development of none has more remarkable progress been made since the days immediately following the Lawrenceville test. For this progress we are indebted chiefly to Alexander J. Wurts. The first alternating-current plants in America used the brass "saw tooth" arrester which was then in general use by the telegraph companies. Bitter experience soon demonstrated the futility of this device when applied to 1100-volt, constant-potential circuits, supplied by dynamos having low internal resistance, and it was soon displaced by a flood of ingenious and more or less effective

arresters, which, in turn, were effectively superseded by the so-called non-arcing metal arrester discovered by Wurts in 1892. The problem was to provide an easy path from conductor to earth for static electricity due to lightning and to prevent the dynamic current following in the path of the static discharge and short-circuiting the system. This, for potentials up to about 25,000 volts, has been effectively accomplished by means of the non-arcing metal cylinders. For higher potentials, the performance of lightning arresters is not yet altogether reliable. The illustration on this page shows a modern lightning arrester outfit for a 25,000-volt circuit. Detail descriptions have been printed in various technical journals and in advertising publications of manufacturing companies.

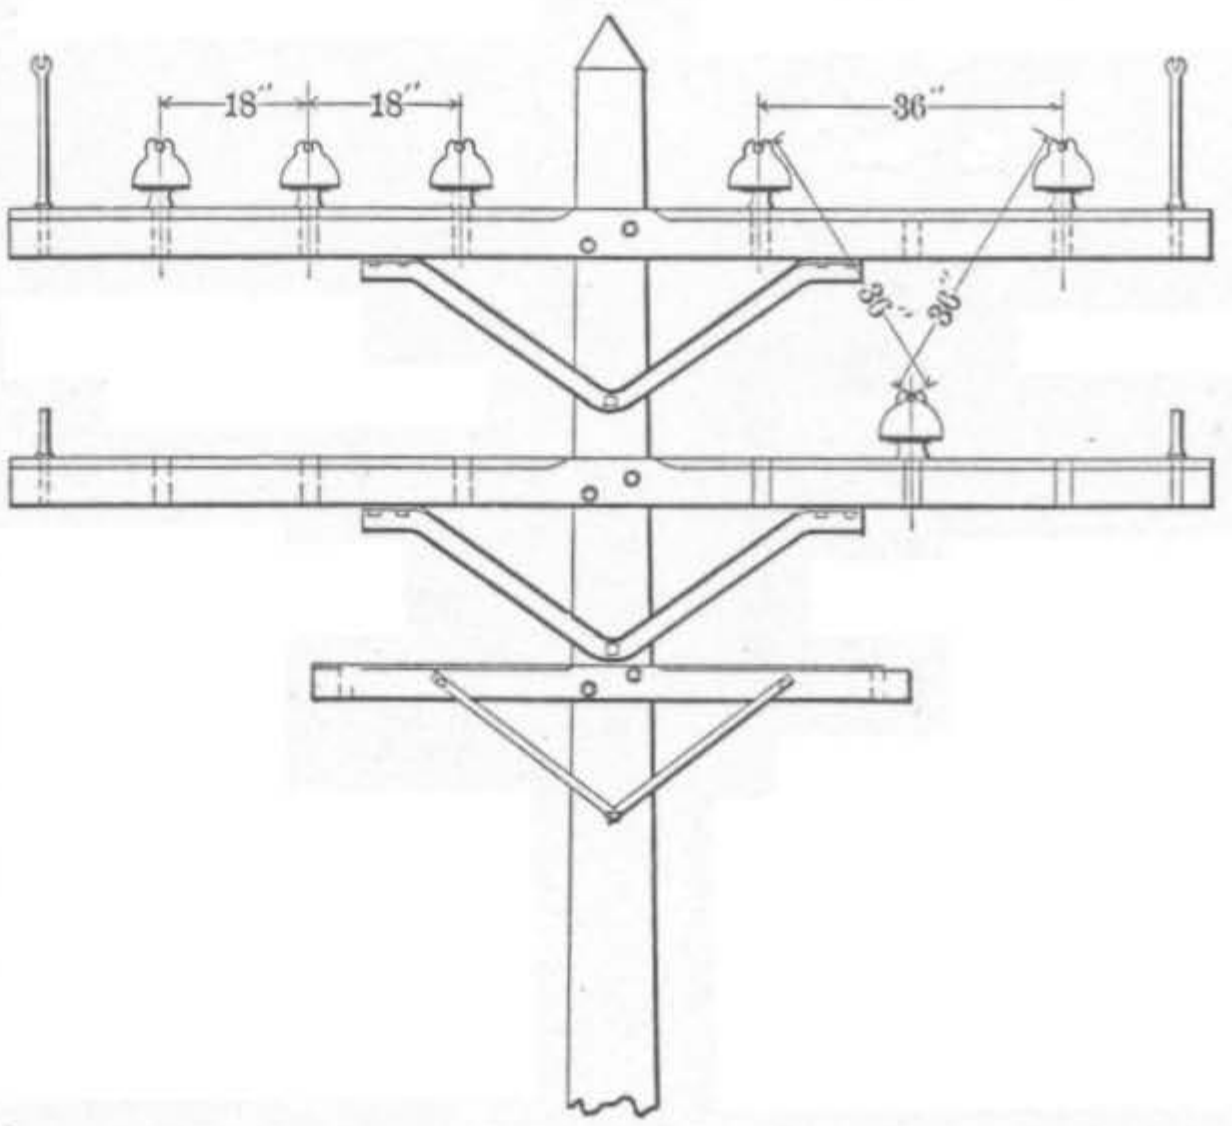


As regards line construction, it is to be regretted that few plants in the United States up to the present time have erected transmission circuits which, from the standpoint of permanence, compare favourably with approved European practice as illustrated, for example, in the illustration on page 120, showing the steel pole line used between Paderno and Milan. For this illustration I am indebted to Mr. Guido Semenza, the very able engineer of this important and interesting plant. Nearly all pole lines in America are of wood, and, so far as insulation is concerned, there is much to be said in favour of this material. In my opinion, however, the lines of the future will use steel poles or towers, widely spaced, and will rely for insulation exclusively upon the insulators to which the conductors are attached. The idea of using steel poles is not new in America.*

The illustration on page 118 shows a design for a steel pole carrying two transmission circuits, as designed under the writer's direction in 1894 by the Pittsburgh Bridge Company and submitted to the Cataract Construction Company with reference to the then proposed transmission from Niagara to Buffalo. It will be noted that the three conductors of each circuit are triangled,

A LIGHTNING ARRESTER FOR 25,000-VOLT ALTERNATING CURRENT CIRCUITS

* Since this article was written, the writer has been furnished, through the courtesy of Mr. Henry Hine, president of the Guanajuato Power & Electric Co., Mexico, with a description of the steel tower construction adopted by that company, which marks a most interesting and important advance in the art of electric power transmission in America, not only by reason of the substitution of steel towers for the usual wooden poles, but also because of the long spans used. Further reference to this remarkable example of modern line con-construction will be made in a future article.

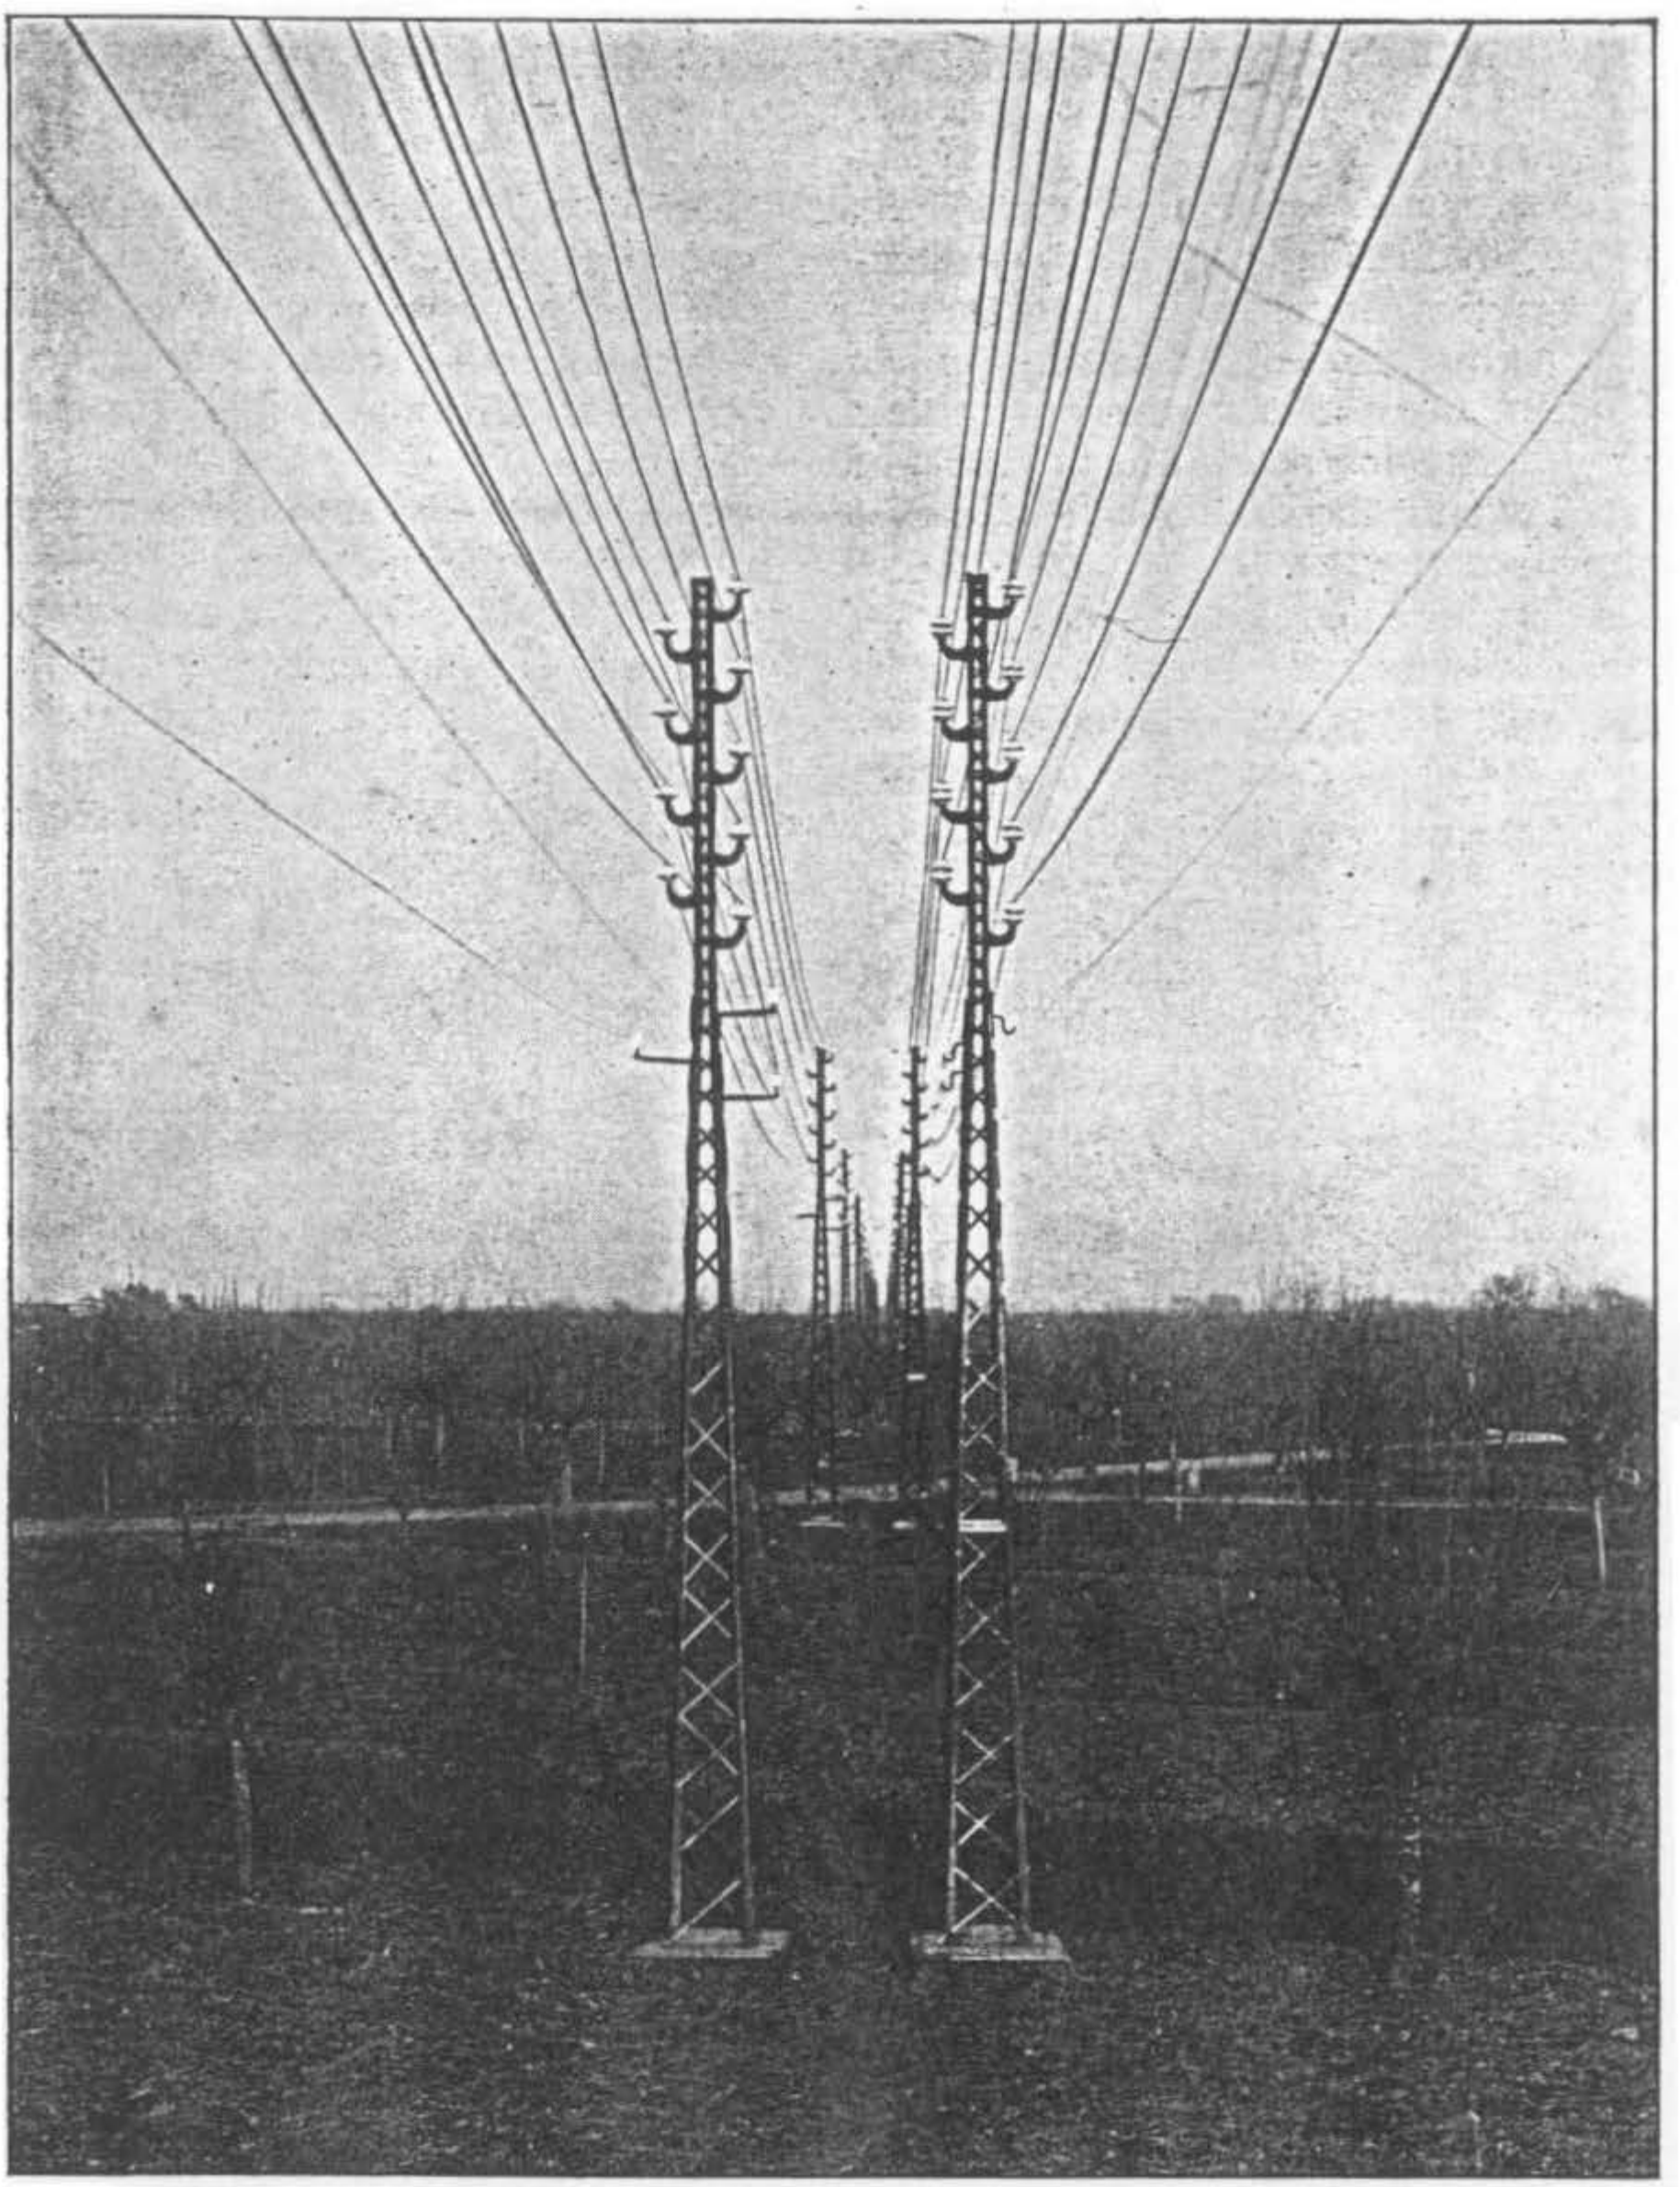


A 40 FOOT STEEL POLE DESIGNED BY THE PITTSBURGH BRIDGE COMPANY

the sides of the equilateral triangle measuring 36 inches.

Unfortunately, this plan was rejected, and the first pole line carrying two circuits was erected between Niagara Falls and Buffalo in line with the plan illustrated on this page, both circuits originally being carried upon the upper cross-arm, the three wires constituting each circuit being spaced at intervals of 18 inches and carried at the same level as shown at the left.

This arrangement was a great temptation to mischievous boys, who threw wires and sticks across the line wire. Owing to the position of the conductors they inevitably came in contact with at least two sides of the circuit, causing tremendous short-circuits, which blazed along the line until the power was cut off. The light of these short-circuits in some cases was seen at a distance of a mile, and unless the power was cut off at the power house they inevitably resulted in burning off and dropping the conductors of the transmission circuit. The triangular arrangement of conductors illustrated on the right hand side of the drawing on this page shows the location of the conductors of the first two circuits as subsequently located. In this position they have given little trouble.



POSITION OF INSULATORS ON THE FIRST NIAGARA-BUFFALO POLE LINE

Enough has been said to show that engineers who to-day are designing electric power plants have available for use much highly important, if not absolutely essential, apparatus which did not exist ten years ago. Efficiency of dynamo, transformer, and motor has improved since then, but it has gained little as compared with the development of such auxiliary apparatus as has been referred to here. The latest dynamo installed at Niagara is not materially more efficient than the first one which was put into commercial operation there in 1895; but line insulators, cable insulation, switches, and relay devices for automatic circuit-breakers are incomparably superior to any that existed at that time.

Doubtless further improvement in respect to details of construction is to be expected, but the apparatus available to-day is such that transmission at 60,000 volts should be more reliable than transmission at 6000 volts was ten years ago. Accurate and extensive knowledge and sound judgment the engineer who designs and installs such a plant must have, but the materials are now available if he knows where to find and how to use them.

Considering the probabilities of future development of electric transmission, it is reasonable to expect that the utilisation of water-powers will continue until practically all of any considerable magnitude are put to work. The ability to employ higher potentials means ability to span greater distances, and thus markets will be found for water-powers which hitherto have been deemed too remote from industrial markets for profitable utilisation. Improved reliability and gradually lessening cost of apparatus will co-operate influentially toward this result, as will also the decrease in rates

STEEL POLE LINE AND CIRCUITS ON THE MILAN-PADERNO TRANSMISSION, ITALY

of interest upon capital which has been so marked in recent years.

It is to be expected also that power plants using steam or gas engines to drive dynamos and distribute power electrically over large districts will be constructed. Recently in Great Britain a number of corporations have been chartered with this object in view. Some of these plants are now under construction, and the commercial results of their operation will be of great interest. So far as I am aware, nothing of this kind on a large scale has been attempted up to the present time in America; but there are undoubtedly districts where such enterprises should be profitable.

The opportunity for profit rests chiefly upon three facts:—(1) that power can

be produced more economically by a very large steam plant than by a small one; (2) that the aggregate power which a central station plant, supplying a certain district, is called upon to develop at any given time is very much less than the sum of the maximum outputs of the small plants required to do the same work; and (3) that an electric motor occupies much less space and requires less attention than a steam plant. A 50,000 horse-power steam plant, supplying electric power for general purposes to a district having a radius of fifty miles, will burn about 3 lbs. of coal per average kilowatt-hour delivered throughout the district, while the average consumption of coal by the steam plants which such a central power plant would displace is usually not less than 10 lbs. per kilowatt-hour.

As regards ratio of the maximum output of the central station to the sum of the maximum outputs of the displaced small plants, definite generalisation is impossible, because everything will depend upon the kind of work done by the small plants. I think it safe, however, to say that this ratio will rarely, if ever, be higher than 2 to 3, and in some instances which have come under my observation it is as low as 1 to 3. In other words, a 50,000 horse-power central station plant will rarely, if ever, fail to do the work of small plants aggregating 75,000 horse-power, and in some instances will be capable of doing the work of small plants aggregating 150,000 horse-power.

Transmission of power from coal fields to large cities works out much less favourably, since in this case it must compete with the alternative plan of transporting the coal to the city or to a point near it and there generating electric power in a steam plant equally economical and equally deriving the benefit which results from the fact that a single large plant can displace a large number of small plants whose aggregate output considerably exceeds its own. In this case, the plant located at a distance from the city must be larger by an amount equivalent to the maximum losses in transmission, and the fuel burned for a given delivery of power in the city will exceed the amount which would be burned if the plant were located in or near the city by an amount proportioned to the average square of the power transmitted.

Generally speaking, the difference in the cost of coal delivered to a plant in the city and the cost of coal delivered to a similar plant located in the coal fields at a distance of 250 miles from the city will not represent as much as 10 per cent. upon the difference in annual cost of the two plants thus respectively located, and when we take into account the possibilities of interruption of service in the case of the plant located at a distance, it appears evident that in the present state of the art of transmission, the better plan is to locate the central station near the city and pay the cost of transporting the coal to the point.

But what may prove to be the greatest of all fields for alternating-current transmission now confronts us in the application of electricity to the operation of railways. The successful substitution of electricity for steam by Ganz & Co., of Buda-Pesth, upon the Valtelina line, in Italy, by which a great economy has been effected in cost of operation of a railway more than sixty miles long, is an object lesson of great significance. Freight as well as passenger traffic is handled successfully under very severe conditions of grade, curvature, and climate, and the economy resulting from the substitution of electricity for steam challenges the attention of railway managers and engineers.

The recent high-speed trials at Zossen, Germany, in which a fifteen-ton car, operated electrically, attained a speed exceeding 131 miles an hour, invite attention in the same direction, and the development of two single-phase, alternating-current motors in America and of two similar motors in Europe, each of which is stated to meet effectively the requirements of railway service, mark by far the most interesting and important practical step of this new century in the use of electricity for power purposes.

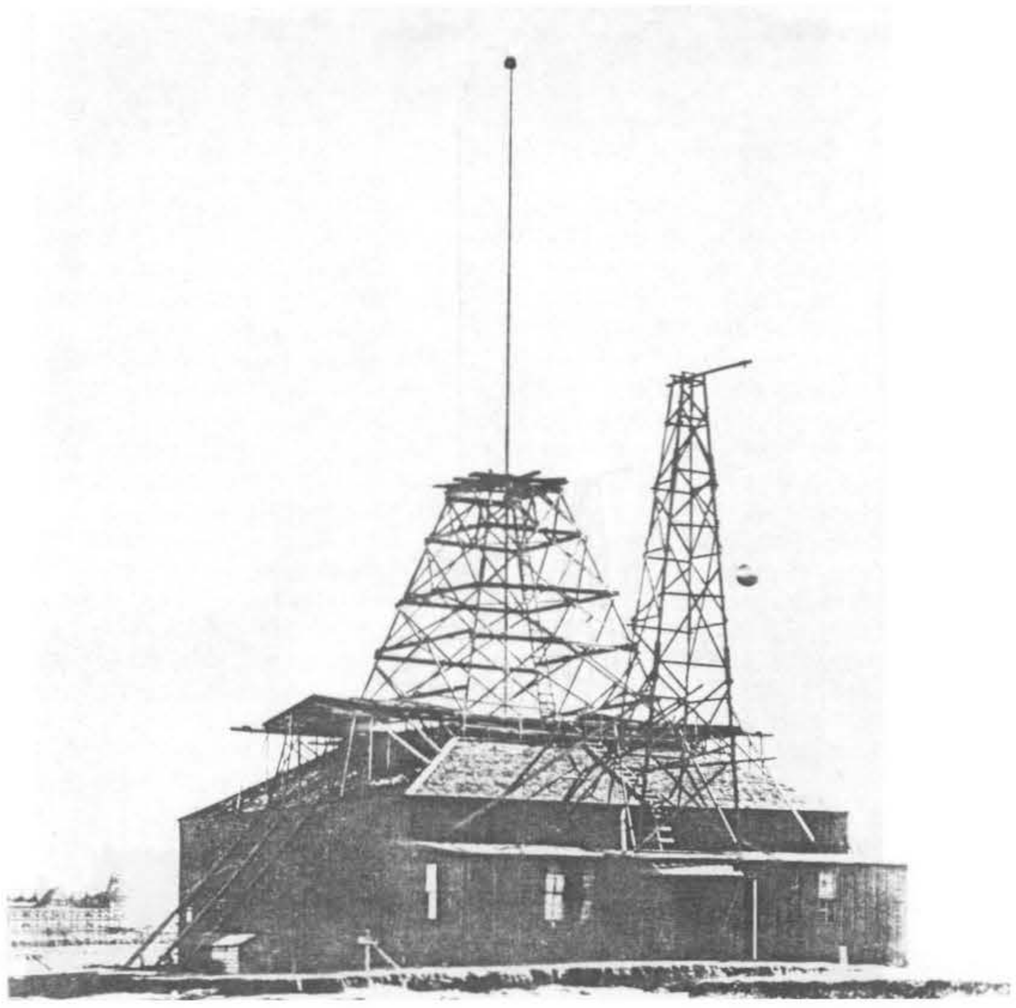


FIG. 1.—TESLA EXPERIMENTAL LABORATORY IN COLORADO, ERECTED DURING THE SUMMER OF 1899.

(The discovery by Mr. Tesla of the stationary waves in the earth was made here.)

THE TRANSMISSION OF ELECTRIC ENERGY WITHOUT WIRES.*

By NIKOLA TESLA.

TOWARD the close of 1898 a systematic research, carried on for a number of years with the object of perfecting a method of transmission of electrical energy through the natural medium, led me to recognize three important necessities: First, to develop a transmitter of great power; second, to perfect means for individualizing and isolating the energy transmitted; and, third, to ascertain the laws of propagation of currents through the earth and the atmosphere. Various reasons, not the least of which was the help proffered by my friend Leonard E. Curtis and the Colorado Springs Electric Company, determined me to select for my experimental investigations the large plateau, two thousand meters above sea level, in the vicinity of that delightful resort, which I reached late in May, 1899. I had been there but a few days when I congratulated myself on the happy choice, and I began the task for which I had long trained myself, with a grateful sense and full of inspiring hope. The perfect purity of the air, the unequaled beauty of the sky, the imposing sight of a high mountain range, the quiet and restfulness of the place—all around contributed to make the conditions for scientific observation ideal. To this was added the exhilarating influence of a glorious climate and a singular sharpening of the senses. In those regions the organs undergo perceptible physical changes. The eyes assume an extraordinary limpidity, improving vision; the ears dry out and become more susceptible to sound. Objects can be clearly distinguished there at distances such that I prefer to have them told by someone else, and I have heard—this I can venture to vouch for—the claps of thunder seven and eight hundred kilometers away. I might have done better still, had it not been tedious to wait for the sounds to arrive, in definite intervals, as heralded precisely by an electrical indicating apparatus—nearly an hour before.

In the middle of June, while preparations for other work were going on, I arranged one of my receiving transformers with the view of determining in a novel manner, experimentally, the electric potential of the globe and studying its periodic and casual fluctuations. This formed part of a plan carefully mapped out in advance. A highly sensitive, self-restorative device, controlling a recording instrument, was included in the secondary circuit, while the primary was connected to the ground and an elevated terminal of adjustable capacity. The variations of potential gave rise to electric surgings in the primary; these generated secondary currents, which in turn affected the sensitive device and recorder in proportion to their intensity. The earth was found to be, literally, alive with electrical vibrations, and soon I was deeply absorbed in this interesting investigation. No better opportunities for such observations as I intended to make could be found anywhere. Colorado is a country famous for the natural displays of electric force. In that dry and rarefied atmosphere the sun's rays beat the objects with fierce intensity. I raised steam, to a dangerous pressure, in barrels filled with concentrated salt solution, and the tinfoil coatings of some of my elevated terminals shriveled up in the fiery blaze. An experimental high-tension transformer, carelessly exposed to the rays of the setting sun, had most of its insulating compound melted out and was rendered useless. Aided by the dryness and rarefaction of the air, the water evaporates as in a boiler, and static electricity is developed in abundance. Lightning discharges are, accordingly, very frequent and sometimes of inconceivable violence. On one occasion approximately twelve thousand discharges occurred in two hours, and all in a radius of certainly less than fifty kilometers from the laboratory. Many of them resembled gigantic trees of fire with the trunks up or down. I never saw fire balls, but as a compensation for my disappointment I succeeded later in determining the mode of their formation and producing them artificially.

In the latter part of the same month I noticed several times that my instruments were affected stronger by discharges taking place at great distances than by those near by. This puzzled me very much. What was the cause? A number of observations proved that it could not be due to the differences in the intensity of the individual discharges, and I readily ascertained that the phenomenon was not the result of a varying relation between the periods of my receiving circuits and those of the terrestrial disturbances. One night, as I was walking home with my assistant, meditating over these experiences, I was suddenly staggered by a thought. Years ago, when I wrote a chapter of my lecture before the Franklin Institute and the National Electric Light Association, it had presented itself to me, but I had dismissed it as absurd and impossible. I banished it again. Nevertheless, my instinct was aroused and somehow I felt that I was nearing a great revelation.

It was on the third of July—the date I shall never forget—when I obtained the first decisive experimental evidence of a truth of overwhelming importance for the advancement of humanity. A dense mass of strongly charged clouds gathered in the west and toward the evening a violent storm broke loose which, after spending much of its fury in the mountains, was driven away with great velocity over the plains. Heavy and long persisting arcs formed almost in regular time intervals. My observations were now greatly facilitated and rendered more accurate by the experiences already gained. I was able to handle my instruments quickly and I was prepared. The recording apparatus being properly adjusted, its indications became fainter and fainter with the increasing distance of the storm, until they ceased altogether. I was watching in eager expectation. Surely enough, in a little while the indications again began, grew stronger and stronger and, after passing through a maximum, gradually decreased and ceased once more. Many times, in regularly recurring intervals, the same actions were repeated, until the storm which, as evident from simple computations, was moving with nearly constant speed, had retreated to a distance of about three hundred kilometers (186 miles). Nor did these strange actions stop then, but continued to manifest themselves with undiminished force. Subsequently, similar observations were also made by my assistant, Mr. Fritz Lowenstein, and shortly afterward several admirable opportunities presented themselves which brought out, still more forcibly, and unmistakably, the true nature of the wonderful phenomenon. No doubt whatever remained—I was observing stationary waves.

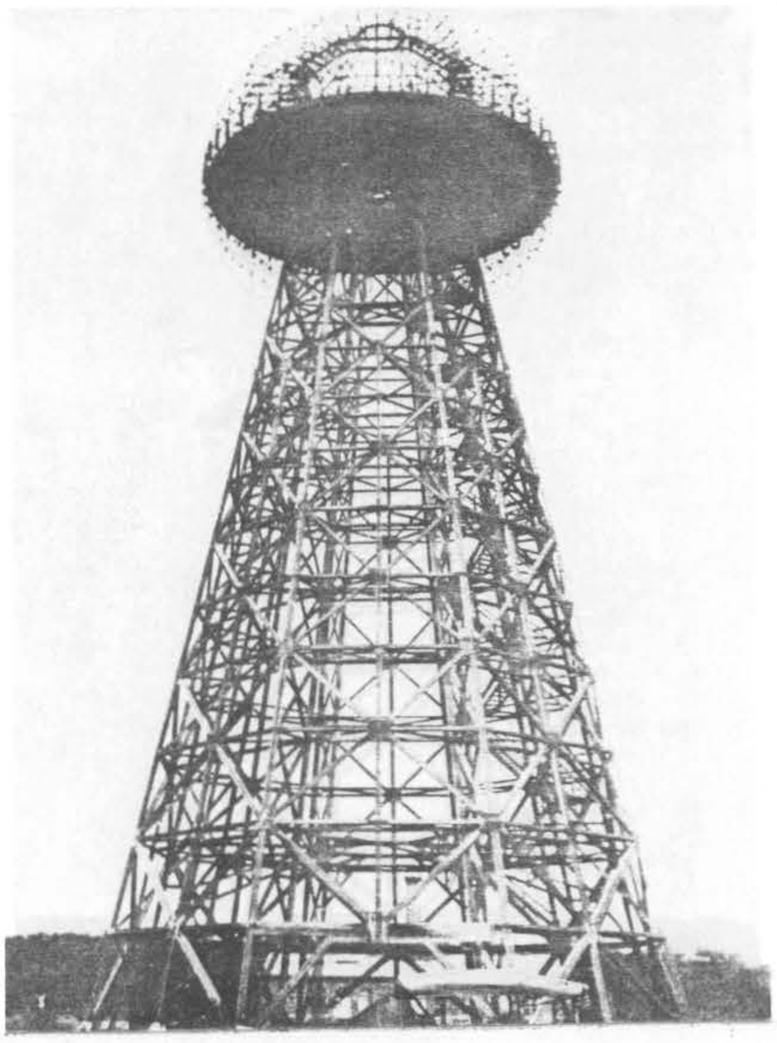

FIG. 2.—TESLA CENTRAL POWER PLANT AND TRANSMITTING TOWER FOR WORLD TELEGRAPHY, AT WARDENCLYFFE, LONG ISLAND, N. Y.

(The tower is a pyramid having eight sides; smallest dimensions across base, 95 feet; height, 154 feet; total height from ground to top, 187 feet; cupola on top, 65.62 feet in diameter.)

* Electrical World and Engineer.

As the source of disturbances moved away, the receiving circuit came successively upon their nodes and loops. Impossible as it seemed, this planet, despite its vast extent, behaved like a conductor of limited dimensions. The tremendous significance of this fact in the transmission of energy by my system had already become quite clear to me. Not only was it practicable to send telegraphic messages to any distance without wires, as I recognized long ago, but also to impress upon the entire globe the faint modulations of the human voice, far more still, to transmit power, in unlimited amounts, to any terrestrial distance and almost without any loss.

With these stupendous possibilities in sight, with the experimental evidence before me that their realization was henceforth merely a question of expert knowledge, patience, and skill, I attacked vigorously the development of my magnifying transmitter, now, however, not so much with the original intention of producing one of great power, as with the object of learning how to construct the best one. This is, essentially, a circuit of very high self-induction and small resistance which, in its arrangement, mode of excitation, and action, may be said to be the diametrically opposite of a transmitting circuit typical of telegraphy by Hertzian or electromagnetic radiations. It is difficult to form an adequate idea of the marvelous power of this unique appliance, by the aid of which the globe will be transformed. The electromagnetic radiations being reduced to an insignificant quantity, and proper conditions of resonance maintained, the circuit acts like an immense pendulum, storing indefinitely the energy of the primary exciting impulses and impressing upon the earth and its conducting atmosphere uniform harmonic oscillations of intensities which, as actual tests have shown, may be pushed so far as to surpass those attained in the natural displays of static electricity.

Simultaneously with these endeavors, the means of individualization and isolation were gradually improved. Great importance was attached to this, for it was found that simple tuning was not sufficient to meet the vigorous practical requirements. The fundamental idea of employing a number of distinctive elements, co-operatively associated, for the purpose of isolating energy transmitted, I trace directly to my perusal of Spencer's clear and suggestive exposition of the human nerve mechanism. The influence of this principle on the transmission of intelligence, and electrical energy in general, cannot as yet be estimated, for the art is still in the embryonic stage; but many thousands of simultaneous telegraphic and telephonic messages, through one single conducting channel, natural or artificial, and without serious mutual interference, are certainly practicable, while millions are possible. On the other hand, any desired degree of individualization may be secured by the use of a great number of co-operative elements and arbitrary variation of their distinctive features and order of succession. For obvious reasons, the principle will also be valuable in the extension of the distance of transmission.

Progress, though of necessity slow, was steady and sure, for the objects aimed at were in a direction of my constant study and exercise. It is, therefore, not astonishing that before the end of 1899 I completed the task undertaken and reached the results which I have announced in my article in the Century Magazine of June, 1900, every word of which was carefully weighed.

Much has already been done toward making my system commercially available, in the transmission of energy in small amounts for specific purposes, as well as on an industrial scale. The results attained by me have made my scheme of intelligence transmission, for which the name of "world telegraphy" has been suggested, easily realizable. It constitutes, I believe, in its principle of operation, means employed, and capacities of application, a radical and fruitful departure from what has been done heretofore. I have no doubt that it will prove very efficient in enlightening the masses, particularly in still uncivilized countries and less accessible regions, and that it will add materially to general safety, comfort, and convenience, and maintenance of peaceful relations. It involves the employment of a number of plants, all of which are capable of transmitting individualized signals to the uttermost confines of the earth. Each of them will be preferably located near some important center of civilization and the news it receives through any channel will be flashed to all points of the globe. A cheap and simple device, which might be carried in one's pocket, may then be set up somewhere on sea or land, and it will record the world's news or such special messages as may be intended for it. Thus the entire earth will be converted into a huge brain, as it were, capable of response in every one of its parts. Since a single plant of but one hundred horse-power can operate hundreds of millions of instruments, the system will have a virtually infinite working capacity, and it must needs immensely facilitate and cheapen the transmission of intelligence.

The first of these central plants would have been already completed had it not been for unforeseen delays which, fortunately, have nothing to do with its purely technical features. But this loss of time, while vexatious, may after all prove to be a blessing in disguise. The best design of which I knew has been adopted, and the transmitter will emit a wave complex of a total maximum activity of ten million horse-power, one per cent of which is amply sufficient to "girdle the globe." This enormous rate of energy delivery, approximately twice that of the combined falls of Niagara, is obtainable only by the use of certain artifices, which I shall make known in due course.

For a large part of the work which I have done so far I am indebted to the noble generosity of Mr. J. P. Morgan, which was all the more welcome and stimulating, as it was extended at a time when those who have since promised most were the greatest of doubters. I have also to thank my friend, Stanford White, for much unselfish and valuable assistance. This work is now far advanced, and though the results may be tardy, they are sure to come.

Meanwhile, the transmission of energy on an industrial scale is not being neglected. The Canadian Niagara Power Company have offered me a splendid inducement, and next to achieving success for the sake of the art, it will give me the greatest satisfaction to make their concession financially profitable to them. In this first power plant, which I have been designing for a long time, I propose to distribute ten thousand horse-power under a tension of one hundred million volts, which I am now able to produce and handle with safety.

The energy will be collected all over the globe, preferably in small amounts, ranging from a fraction of one to a few horse-power. One of its chief uses will be the illumination of isolated homes. It takes very little power to light a dwelling with vacuum tubes operated by high-frequency currents, and in each instance a terminal a little above the roof will be sufficient. Another valuable application will be the driving of clocks and other such apparatus. These clocks will be exceedingly simple, will require absolutely no attention, and will indicate rigorously correct time. The idea of impressing upon the earth American time is fascinating and very likely to become popular. There are innumerable devices of all kinds which are either now employed or can be supplied, and by operating them in this manner I may be able to offer a great convenience to the whole world with a plant of no more than ten thousand horse-power. The introduction of this system will give opportunities for invention and manufacture such as have never presented themselves before.

Knowing the far-reaching importance of this first attempt and its effect upon future development, I shall proceed slowly and carefully. Experience has taught me not to assign a term to enterprises the consummation of which is not wholly dependent on my own abilities and exertions. But I am hopeful that these great realizations are not far off, and I know that when this first work is completed they will follow with mathematical certitude.

When the great truth accidentally revealed and experimentally confirmed is fully recognized, and this planet, with all its appalling immensity, is to electric currents virtually no more than a small metal ball, and that by virtue of this fact many possibilities, each baffling imagination and of incalculable consequence, are rendered absolutely sure of accomplishment; when the first plant is inaugurated and it is shown that a telegraphic message, almost as secret and non-interferable as a thought, can be transmitted to any terrestrial distance, the sound of the human voice, with all its intonations and inflections faithfully and instantly reproduced at any other point of the globe, the energy of a waterfall made available for supplying light, heat or motive power, anywhere—on sea, or land, or high in the air—humanity will be like an antheap stirred up with a stick. See the excitement coming!

NOTES.

Tesla in the "Daily Mail."—Marvels beyond belief—*our* belief, at any rate—are to be accomplished by Mr. Nikola Tesla by-and-by, according, of course, to the *D. M.*:—

"An enormous mushroom-shaped tower has just been completed at Wardenclyffe, Long Island, by Mr. Nikola Tesla, the distinguished electrical inventor. From this tower Mr. Tesla is now preparing to put into operation the most daring and amazing scheme ever conceived in the development of wireless telegraphy.

"For over four years Mr. Tesla has been hard at work almost day and night experimenting and endeavouring to make his marvellous theory practicable. From time to time during that period he had intimated vaguely the immensity of his plan, and the equally tremendous results that would follow its introduction, and now, at last, he has announced his preparedness to put his theories to their first practical test.

"For a large part of the work already done Mr. Tesla is indebted to the generosity of Mr. J. Pierpont Morgan, who is extremely interested in the scheme."

Poor Mr. J. P. M.

"Briefly explained, Mr. Tesla's assurances of what we may expect in the next few years are as follows:—

"A ceaseless day and night service of millions upon millions of volts of electricity from the Canadian Niagara Power Co.'s electric power plants at Niagara Falls to the Wardenclyffe tower, the electric power being forwarded from there by Tesla's wireless system to New York City for the purpose of illuminating the entire metropolis, running elevated and underground trains and tramway cars, operating lifts, motor-cars, trucks, and ferry-boats, furnishing heat, and even winding up clocks and making them keep perfect time by a system of half-hourly regulation.

"Each will distribute about 10,000 H.P. of wireless electricity under a tension of one hundred million volts. Mr. Tesla declares that he is able to produce and handle that much with perfect safety from one tower.

"Among his other schemes Mr. Tesla proposes a perfect system of world-wide wireless telegraphy through which widely separated friends will be able to converse instantaneously and without the slightest danger that their wireless conversations will be overheard by a third person.

"Little instruments about the size and shape of a watch will be carried in the vest pocket and will record market quotations, races, and important news features.

"Another little watch-like instrument is one with a dial face by means of which the wearer can transmit and receive wireless messages to and from friends many miles away. Watches of both sender and receiver will be keyed to a certain pitch to prevent their communications from going astray or falling into the watches of disinterested third persons."

We envy the *D. M.'s* good luck in coming into possession of these wonderful items of news; but we fear they are *bad* news.

The Colorado Springs Gazette July 2, 1904

TESLA'S ELECTRICAL STATION IS SOLD FOR VALUE OF LUMBER

The Nicola Tesla experimental electrical station, near the Deaf and Blind school east of the city, has been abandoned. The building still stands there but even that trace of the visit of the great electrician is soon to disappear, for the station has been sold.

Five years ago last May, Tesla decided to construct this station and did so. He stated that he intended to carry on wireless telegraphy experiments from the summit of Pike's Peak to this station. So far as can be learned he never really carried on any important experiments here. He left this city shortly after erecting his station and has not returned since. He was recently sued for an electricity bill, for power furnished by the Colorado Springs Electrical company. He failed to answer the summons either personally or by an attorney and his property was advertised for sale. He later sent the sheriff enough money to cancel the bill and the station again became his property.

Supposedly on his order the property has been sold; that is, all but the apparatus. This has been stored and will probably be shipped to Tesla in the near future.

The building has been sold to C. E. Maddocks, who is erecting a new house in Ivywild and will use the lumber in its construction or for some other purpose about his property, it is understood. The piping has been sold to St. John Bros.

TESLA "WIRELESS" STATION ABANDONED

Plumber Has Bought Pipes and Some One Else Lumber of Colorado Experiment House.

[SPECIAL DESPATCH TO THE HERALD.]

COLORADO SPRINGS, Col., Sunday.—Nikola Tesla has abandoned his wireless telegraph station which he established here in 1898, and the lumber has been sold to a party who will utilize it in the construction of a residence.

A plumber has bought the pipes connecting the station with the city water system and with the Colorado Springs Electric Company's batteries. The instruments will be shipped to New York. The station stood at an altitude of seven thousand feet, facing Pike's Peak.

[1133.]—Tesla Coils.—I know of no book treating solely on this subject. In my "Electrical Instrument Making for Amateurs" you will find directions for making two forms, along with good constructive drawings. If there is anything I can assist you in as regards other portions of the high frequency apparatus, such as resonators, &c., I shall be only too pleased to do so, if you will only let me know in these pages what you require.

UPHOLDS TESLA PATENTS.

United States Circuit Court of Appeals Reverses Judgment of Lower Body.

[SPECIAL DESPATCH TO THE HERALD.]

BOSTON, Mass., Friday.—The United States Circuit Court of Appeals to-day handed down a decision in the case of the Westinghouse Electric and Manufacturing Company vs. the Stanley Instrument Company, reversing the judgment of the Circuit Court, which dismissed a bill brought with a view to prevent infringement of patents issued to Nikola Tesla relating to the conversion of alternating currents of electricity into a continuous current.

The defendant had contended that the invention was not addressed to the utilization of two-phased currents in a motor, but to a new way of producing the necessary two out-of-phase currents, and that this specific way of producing two out-of-phase currents was old and well known in the art.

Tesla Patents Upheld.

The U. S. Circuit Court of Appeals at Boston has reversed the decision of the lower court and decided in favor of the Westinghouse Electric Manufacturing Company against the Stanley Instrument Company, upholding the Tesla patents, relating to the conversion of alternating currents of electricity into a continuous current.

Sustaining Tesla Patent on Appeal.

The United States Circuit Court of Appeals at Boston on September 9 handed down a decision in the case of Westinghouse Electric & Manufacturing Company vs. Stanley Instrument Company, reversing the judgment of the Circuit Court, which dismissed a bill brought with a view to prevent alleged infringement of patents issued to Nikola Tesla relating to conversion of alternating currents of electricity into a continuous current. The lower court dismissed the bill on the ground that complainant had failed to establish by sufficient proofs a conception of the invention by Tesla prior to April 22, 1888, the date of a certain publication in Italy known as the Ferraris publication. Complainant appealed, and the Appellate Court sustains the appeal, remanding the case to the Circuit Court with a direction to enter a decree for plaintiff for an injunction against defendant restraining the latter from infringing the patents, numbered respectively 511,559 and 511,560, and for an accounting.

Defendant had contended that the alleged invention was not addressed to the utilization of two-phased currents in a motor, but to a new way of producing the necessary two out-of-phase currents; that this specific way of producing two out-of-phase currents was old and well known in the art, and was old and well known as an equivalent of the method in a prior patent; that all the methods of producing two or more out-of-phase alternating currents set out in the Tesla patents were, in and of themselves, old and well known in the art as means and methods of producing such out-of-phase currents; and that their laws and limitations had been known and set out in a way not even approximated in accuracy or fulness in any of the Tesla patents. Respondent further maintained that Dr. Kenney had explained the fact that the invention in the patents involved merely the substitution of one means of obtaining two-phase currents for another means; and that he showed that these two means were old and well known equivalents.

The Court says in regard to the contention: "Of course all this was with the purpose of maintaining that there was no invention in any view of the patents now in issue. It unavoidably concedes, however, that, if there were invention, it was fundamental. When under special circumstances a particular practical application of a known principle proves to be of advantage in the arts, and yet the thought of making it had not occurred to those expert therein, such application, at times, involves invention. The corollary of this proposition, which we will apply later, is that, in cases of this character, where the originator has boldly struck out into a practical application, and stated it, though only in general terms, he has, for the most part, made his conception clear, even though the mechanical details have not been expressed or thought out. Therefore Professor Main was right in testifying that, if Tesla made clear his conception in a general way, he made clear his invention, leaving the artisan skilled in electrical science to work out the practical details required in applying what was previously within the bounds of philosophical knowledge.

"With reference to the apparent lack of supporting proof on the part of complainant which has been very much pressed against it, it must be conceded, as is apparent from the general tone of the record and from the way in which the case has been developed before us, that the patent was long acquiesced in. It is also certain that an interference was declared between Ferraris and Tesla and decided in favor of the latter. The difficulty which pressed itself upon us on the question of infringement grows out of the fact that the amount of power used by respondent is very minute. Nevertheless it is power developed, as set out by Blathy's claims, by 'a metallic rotating body,' and transmitted to a 'suitable counting apparatus, operated by the same rotating body.' If the device stopped with 'a metallic rotating body' and some method other than a counting machine operated by it was used for determining the number of its revolutions, we might not be able to charge respondent with infringing. We might then well apply the proposition of respondent that a mere meter is in a different art from a motor, but as it does not stop there we must look further. The Tesla invention, in issue, as already explained by us, derives its right to recognition from the fact that it was applied to the production of power. The ingenuity of Tesla was displayed in the conception of an adaptation to a particular use."

EDITORIAL COMMENT

The Tesla Motor and the Polyphase System

The types of alternating-current apparatus which are in use to-day have resulted from a process of evolution which has been going on for many years and in which the polyphase induction motor has been the fundamental element. The announcement of the polyphase induction motor and of the polyphase system were made by Mr. Tesla in 1888. The motor excited much interest and expectation. The polyphase system received little consideration. The motor, however, was helpless without a supply of suitable current. The alternators of that day were single-phase, they gave 120 to 133 cycles; alternators and transformers were ill adapted for supplying out-of-phase current. Persistent work, not only in the design and development of the motor but in that of the system as well was required before commercial success could be secured. In reaching this point it was not only necessary to overcome preconceived ideas of the public, but the electrical workers themselves had to unlearn, or at least readjust much of the information which they had acquired in connection with direct-current and single-phase alternating current apparatus and practice. In point of fact the Tesla invention was not merely a motor, but a system. Commercial men and engineers who did not understand the problems involved were naturally impatient and critical because the Tesla motor was not immediately supplied for operation upon existing circuits and in connection with the then prevalent types of generators. As a matter of history it is the Tesla principle and the Tesla system which have been the directing factors in modern electrical engineering practice. Alternators are now polyphase; they are of low frequency, they have close inherent regulation. All of the long distance systems for power transmission involving hundreds of installations, hundreds of thousands of horse-power and many millions of dollars of capital use the polyphase system. Nearly all of the great central stations for city railway and lighting service, even when the consumption circuits are supplied with direct current employ low frequency polyphase alternators. There is scarcely an important city or town in the country that has not a polyphase

plant and polyphase apparatus is largely used for power distribution in industrial establishments.

This evolution has involved far more than the mere perfection of the motor. In fact polyphase motors as made prior to 1890 if operated in connection with modern generators would probably be more successful than the motors of to-day if operated in connection with polyphase alternators of the types first employed. The early polyphase alternators were small, they were of high frequency, they were of poor regulating qualities. Changes have been made in alternators and in transformers. Parallel operation of alternators has become a necessity, imposing exacting problems in the design and operation of steam engines. The extent to which everything in modern electrical power work has been affected by Tesla inventions makes it apparent that the polyphase motor which he proposed was no simple and isolated thing, but it was the central factor in a great and comprehensive system. The whole trend and evolution for the past sixteen years has been in the development of the polyphase system primarily that it may operate the polyphase induction motor. The realization of the Tesla invention was looked for simply in a motor to be forthcoming in a few months; it has come in an evolution of engineering practice which has been the work of years.

CHAS. F. SCOTT.

Tesla Patents Upheld in Stanley Instrument Case.

An opinion was handed down September 9th by the Circuit Court of Appeals for the first circuit in the case of the Westinghouse Electric and Manufacturing Company, complainant and appellant, against the Stanley Instrument Company, defendant and appellee, known as the "Stanley instrument case," the case having been appealed from the United States Circuit Court for the District of Massachusetts. The Court of Appeals reversed the decree of the lower court, which was in favor of the defendant. The opening and closing paragraphs of the opinion of the court, written by Judge Putnam, are of interest, and are here given:

There is so much judicial literature bearing on this case that only a brief preliminary statement is required. The bill alleges an infringement of the two claims of letters patent for an invention, No. 511,559, issued to Nikola Tesla on December 26, 1893, on an application filed on December 8, 1888, and of the first claim of No. 511,560, issued to Tesla on the same December 26th, on an application filed on the same December 8th. No. 511,559 is captioned "Electrical Transmission of Power," and opens with the statement that Tesla had invented "certain new and useful improvements in electrical transmission of power." No. 511,560 is captioned "Systems of Electrical Power Transmission," and opens with the claim that Tesla had invented "certain new and useful improvements in systems of electrical power transmission." The claims of No. 511,559 are as follows:

"1. The method of operating motors having independent energizing circuits, as herein set forth which consists in passing alternating currents through both of the said circuits and retarding the phases of the current in one circuit to a greater or less extent than in the other.

"2. The method of operating motors having independent energizing circuits, as herein set forth, which consists in directing an alternating current from a single source through both circuits of the motor and varying or modifying the relative resistance or self-induction of the motor circuits and thereby producing in the currents differences of phase, as set forth."

The claim of 511,560 in issue is as follows:

"1. The combination with a source of alternating currents, and a circuit from the same, of a motor having independent energizing circuits connected with the said circuit, and means for rendering the magnetic effects due to said energizing circuits of different phase and an armature within the influence of said energizing circuits."

The bill was dismissed by the Circuit Court by an opinion passed down on March 11, 1903, 129 Fed. Rep., 140. The only reason for dismissal given was that the complainant had failed to establish by sufficient proofs a conception of the invention by Tesla prior to April 22, 1888, the date of a certain publication in Italy known as the Ferraris publication. The opinion refers to one of the Circuit Court of Appeals for the second circuit, Westinghouse Company vs. Catskill company, 121 Fed. Rep., 831, passed down on February 25, 1903, wherein it was held that the proofs were insufficient to establish invention by Tesla prior to April 22d, as rendering unnecessary an extended statement by himself. Thereupon, the complainant appealed to us.

The patents in suit relate to the conversion of alternating currents of electricity into a continuous current. The latest condition of the prior art is shown by patents issued to Tesla under date of May 1, 1888, referred to over and over again in the judicial literature on this topic. These describe a system "of electrical power transmission in which the motor contains two or more independent energizing circuits through which were caused to pass alternating currents," "conveyed directly from the generators to the corresponding motor coils by independent lines or circuits." The improvement of the patents in suit dispenses with one of the lines, or circuits.

* * * * * * *

It is not necessary for us to discuss whether what Tesla applied his inventive ability to was a "great engineering problem," as described by plaintiff; but it was a problem practically unsolved in the then state of the art, and of such a character that its solution was certainly a useful one. Therefore, the invention, according to settled rules, is to be protected to its fullest extent unless something of a positive character, either in the patent itself or elsewhere, prevents. It is true that Tesla's specification indicates strongly that he probably had not in mind the application of his invention to any motors except his own. Possibly he valued no other two-phased alternating-current motors, or he conceived that there were no others; so that naturally the practical application which he had in mind was limited accordingly. Nevertheless, he is entitled to the advantage of the well-settled rule by virtue of which an inventor who has patented his invention, is entitled to all the uses to which it may be applied, of the class to which he himself practically applied it. Therefore, we do not perceive how, on any rule relating to the fundamental nature of inventive conceptions, or to the construction and effect to be given to the specifications and claims in patents for invention, it can be held that the respondent can escape, for any reason we are now discussing, the charge of infringement.

Our observations so far have been more particularly with reference to the phraseology of the only claim of patent No. 511,560 in issue. The claims of patent No. 511,559, so far as the topic we are discussing is concerned, are as broad as the single claim of patent No. 511,560. It is true they contain the words "as herein set forth," which are not found in the other patent; but these words connect directly with the words "independent energizing circuits," and they do not necessarily relate, either grammatically or by any reasonable demands of the rules of construction, to any particular description of motors. Therefore, within the rules stated in Reece Button-Hole Company vs. Globe Button-Hole Company, ubi supra, by virtue of which all expressions in specifications or claims are to be held to sustain the actual invention so far as they can reasonably be so construed, this one does not stand in the way of our giving, so far as the topic we are discussing is concerned, as broad a construction to patent No. 511,559 as to the claim of patent No. 511,560 in issue.

The difficulty which presses itself upon us on the question of infringement, grows out of the fact that the amount of power used by the respondent is approximately what is described by it as negligible; that is very minute. Nevertheless, it is power developed, as set out by Blathy's claims, by "a metallic rotating body," and transmitted to a "suitable counting apparatus, operated" by the same rotating body. If the device stopped with "a metallic rotating body," and some method other than a counting machine operated by it was used for determining the number of its revolutions, we might not be able to charge the respondent with infringing. We might then well apply the proposition of the respondent that a mere meter is in a different art from a motor: but, as it does not stop there, we must look further.

The Tesla invention in issue, as already explained by us, derives its right to recognition from the fact that it was applied to the production of power. In that respect, it falls within the limited class referred to or described by us in Davey Company vs. Isaac Prouty & Co., 107 Fed. Rep. 505, 509, 510, 511. The adaptation of the tortional spring which laid the basis of Western Electric Company vs. Larue, 130 U. S. 601, was a marked instance of this class of cases. The ingenuity of Tesla was displayed in the conception of an adaptation to a particular use; and any adaptation which did not involve that conception could hardly infringe. Therefore, as it may well be that, if the counting mechanism was of a kind not operated by the "metallic rotating body" we should not be compelled to find infringement, we hesitate in view of the minute amount of energy exerted. But Blathy did not merely reproduce the academic experiments which must have preceded Tesla. While Tesla uses the word power, he makes no maximum nor minimum: and it is entirely conceivable that, for certain fine work, or work of a peculiar character, the minimum may be of the utmost value. Therefore, we are unable to make any distinction on this account.

Probably we ought to refer to what is spoken of by the parties as Baily and Deprez. We apprehend that Deprez is disclosed by what is known as "Deprez French Patent of 1870," and that Baily is represented by the article in the Philosophical Magazine of October, 1870. These are each relied on by the respondent. Baily was seeking simply a revolving disk, and not looking beyond that. He did not attempt to transmit that electrical power which, as we have shown, was the soul of Tesla's invention, and which we have also shown is involved in the infringing device, although, perhaps, to a minimum. It is apparent, also, that Baily did not concern himself about alternating currents as such; and it is not at all clear that he proposed to make use of them at all. Deprez, on the other hand, made commutators necessary elements in his device, which essentially distinguishes him from both the complainant and respondent, and lays him out of the case without the necessity of further discussion.

Possibly, relating to some other infringers than those at bar, we might be compelled to determine more positively than we have the construction of some of the claims which are put in issue here, pertaining to the two patents in suits. For the present case, however, any further investigation or discussion relating to them would be purely academic and of no practical importance. The infringement by the respondent relates entirely to the method by derivation, or self-induction, which for present purposes, are the same; and, so far as that is concerned, it can make no possible difference as to practical results whether the injunction and accounting relate to all the claims in issue or only to one or two of them. Therefore, in view of the construction which we are now inclined to give the claims, as already stated, we hold that the relief granted should relate to all.

We wish to call attention to the fact that, at various points, the respondent has referred to the affidavits filed in connection with the motion to the

Circuit Court to reopen the case, as though they were adverse to the complainant, and, especially, as though contradicting, in one important particular, the testimony of Mr. Page. On the other hand, at some points, the complainant has undertaken to strengthen its case by reference to the same affidavits. We reject all these, and open the record only so far as it is properly before us. To do otherwise would be to enter on a field which has not been explored by the parties according to proper rules of procedure.

The decree of the Circuit Court is reversed; the case is remanded to that court, with instructions to enter a decree in favor of the complainant for an injunction and an accounting, and to take such further proceedings as may be required not inconsistent with this opinion; and the appellant recovers the costs of this appeal.

Wireless Telegraph Aerial Wires and Earths.*

BY A. FREDERICK COLLINS.

HISTORICAL.

IN a patent granted to Thomas A. Edison, dated December 29, 1901, means are shown for transmitting signals without wires by elevating plates of metal on poles or by balloons. The aerial wire was connected to one terminal of a secondary coil with the opposite terminal leading to the earth; while this is perhaps the earliest reference to aerial wires and earth plates, the method does not employ either a spark-gap or a wave detector for oscillatory currents. In Amos E. Dolbear's patent, issued in 1886, no reference is made to the elevation of the capacities he suggested for the equalization of the coefficients of the circuit connected with the earth. In 1895 Isadore Kitsee obtained a patent for signaling without wires and indicated how one terminal of the system was extended vertically to an elevation approximating the height of a vessel's mast. The antenna and earth utilized by Prof. Popoff in his meterological receptor in 1895 and that by Signor Marconi in his electric wave transmitter, the patent application of which was filed in England in 1896, are the earliest references to the subject of aerial wires and grounds in connection with electric wave wireless telegraphy. In Nikola Tesla's British specification, filed October 21, 1897, he describes a method of producing "a very high electrical pressure, conducting the current thereby to earth and to a terminal at an elevation." The various designs for aerial radiators and antennæ employed in different systems will be treated in sequence in the text appertaining to their application in practice.

THEORETICAL.

There are two theories relating to the probable capacity of the earth and several concerning the rôle the earth plays in the operation and propagation of electric wave signals. The true solution of the problems presented by the earth might prove the key to syntonic wireless telegraphy. In one of the two theories referred to the earth is considered as a sphere insulated in space; the second and opposition theory assumes the earth with its surrounding envelope of air to be a condenser. Koepsel[1] by a formula in electrostatics for the potential of a charged sphere insulated in space deduced a result showing the earth's capacity to have a low value and comparable with artificial capacities used in wireless telegraph practice.

The second theory treats the earth and air as if they were two concentric spherical shells, the medium between them representing its specific inductive capacity, when their capacity will be the same as in the case of two parallel plates with their surfaces brought in close proximity with each other in the form of a condenser. If, as the first theory postulates, the earth is a single spherical shell insulated in space, its capacity must necessarily be very limited, since a single coating on a glass jar would be incapable of acquiring more than the slightest charge; but if the stratum of atmosphere holds a charge opposite to that of the earth, then it may be likened to a complete Leyden jar with its inner and outer coatings, and its capacity would be enormously increased. The importance of knowing absolutely the capacity of the earth cannot be overestimated, but could such conclusions be thus positively ascertained, the density of the charge at a given point could only be taken as a theoretical standard; for, owing to the differences of atmospheric densities, the electric charge may be maximum or minimum at any point at any given instant, and even then of a different sign.

Many different views have been submitted to explain the relation of the earth to the radiating and receiving systems; among the most prominent may be mentioned the following: (*a*) that high-frequency currents are projected from the earthed terminal of the oscillator, whence they are conducted by the earth to the resonator; (*b*) that the earth acts simply as a local capacity for the aerial wires; and (*c*) that the earth, having a large value, serves to tune the oscillator and resonator, since both being grounded would represent the same capacity. As to the nature of the earth as a conducting medium for electric waves there is also a variance of opinion; by those advocating sliding waves the sea is regarded as opaque to electric waves, and it is claimed that in this it fulfills Maxwell's law in that salt water is a conductor of electricity. Others voice the opinion that the sea will transmit electric waves, since salt water does not follow the general law for conductors, in that it conducts by electrolytic action. One fact, however, is positively known, namely, that electric waves are much more easily transmitted over salt water than over fresh water or land. Whatever these conditions may be, it is well known that if a metallic conductor, as a lightning rod, be extended upward in the air and its lower terminal connected with the earth, a constant current will flow through it, equalizing in a small measure a difference of potential that is always present. If this conductor is divided and the resulting terminals form an air-gap, the potential difference may be measured by a galvanometer, or if the air-gap is microscopic in size sparks will pass; if a detector of the coherer type is inserted in the gap the filings will cohere under certain meterological conditions and the restoration of the charge will be indicated. In practice these atmospheric disturbances often produce characters on the tape of the recording instrument, and these untoward indications are called "X's," or strays. The purpose of the aerial wire, on the one hand, is to send out transverse vibrations in the ether in the form of electric waves, and on the other, to receive them; it was ascertained by Dr. Slaby and Prof. Braun that the proper length of the aerial wires should be one-fourth the length of the emitted wave, and therefore the radiator and antenna should have as nearly the same height as possible.

A law relating to the distance over which electric waves may be transmitted with a given height of aerial wire was deduced empirically by Marconi very early in the practice of the art. This law states that with a given current, instruments of standard dimensions and all other factors being equal, the distance to which signals may be transmitted increases as the square of the length of the radiating wire; or, graphically, if a wire 20 feet in height will transmit one mile, a wire 40 feet in height will send waves four

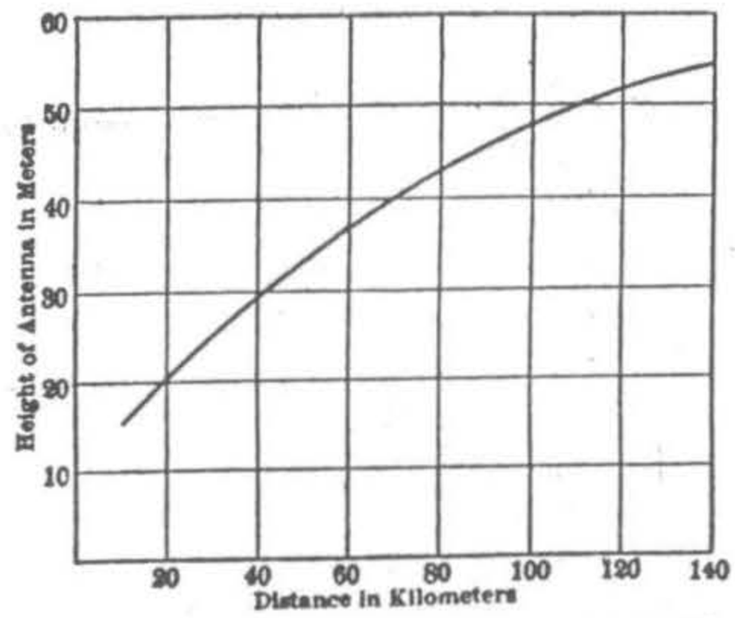

FIG. 1.—CURVE OF TRANSMISSION DISTANCES.

miles, and one 80 feet in height will transmit waves sixteen miles, *et cetera*. This general law was mathematically evolved by Prof. Ascoli, who deduced his conclusions in accordance with Neumann's formula and found the reciprocal action to be proportional to the square of the length of one of the two aerial wires if these are of equal length, and in simple inverse proportion of the distance between them.

It would seem that the empirical law of Marconi and the deductions of Ascoli are subject to modification for Captain Bonomo, of the Royal Italian Navy has determined that the distance to which signals may be transmitted is in accordance with the formula $L = O.15 \sqrt{D}$ where L represents the length of the aerial wire, D the signaling distance in meters and $O.15$ is a constant. Where a number of parallel wires are employed instead of the single vertical wire as first used by Marconi this apparent discrepancy is accounted for, not only because of the greater radiation of energy, but also in virtue of a longer wave length emitted.

The intensity of the oscillations does not diminish with the increase of distance if the length of the aerial wires is increased in proportion or as the square of the distance; therefore, by doubling the height of the aerial wires the distance of signaling may be four times as great. In a series of experiments carried out by Dr. Slaby to determine with precision the exact height of aerial wire required to transmit messages over a given distance the curve shown in Fig. 1 was plotted. Starting with an initial energy of 746 watts, the curve represents the maximum distance for transmission over bodies of salt water, with the Slaby-Arco standard station apparatus. Considerable latitude has been allowed for meterological, climatic changes and unfavorable conditions of the year, as, for instance, the heated atmosphere of the summer months. The accuracy of the

*From advance sheets of "Wireless Telegraphy; Its History, Theory and Practice" in press.

[1]Koepsel, Dingler's Polytechnisches Journal, June, 1903.

curve has been tested carefully, and while the sending and receiving instruments are calibrated in accordance with the curve, their actual working distance may be much greater, as, for instance, it was found possible to obtain messages between the *Deutschland* and the *Duhmen*, a distance of 150 kilometers, whereas the curve gives the working distance as 80 kilometers. The photo-electric effect of sunlight on aerial wires was deduced by Marconi[1] upon the conclusions reached by Hertz[2] in 1887, who found that the effect of one electric spark from an induction coil on another had a tendency to diminish the size of the latter, and that this curious result was due to the ultra-violet radiation—in which the disruptive discharge is rich—dissipating the charge of electricity stored in the second oscillatory system. Righi[3] attributed the cause to the ultra-violet radiation producing correction or the process of dispersing negative electricity, the charge being carried away by the molecules of air. Righi also determined that ultra-violet radiation charged wires, when insulated, with positive electricity, and Elster and Geitel have been able to show the dissipating influence of not only sunlight, but of diffused daylight on conductors. This phenomenon was observed at the antennæ by Marconi when he received signals a distance of 2,099 miles from Poldhu, Cornwall, England, on the steamship *Philadelphia*. During the tests made on this trip it was ascertained on one occasion that the signals were distinct and clear at night for 2,000 miles, but in daylight the signaling distance was only a fourth part as great, or 500 miles.

PRACTICAL.

In practice it is of vital importance to maintain absolute insulation of the aerial wires and earthed terminals of the radiator and resonator, for in utilizing high-frequency, high-potential currents leakage becomes excessive should any portions of the systems come in contact with masts, buildings or other physical appurtances. Where the aerial and ground wires are sustained or supported heavy glass or porcelain insulators are desirable. The wires themselves should be highly insulated, since this protects the oscillatory currents from dissipating their energy in the atmosphere and does not retard the action of the electric waves, for insulators are transparent to them.

METHOD OF SUSPENSION.—A simple and efficient method for suspending aerial wires from the yardarm of a mast is shown in Fig. 2; the mast is represented at 1, the yardarm 2, insulator 3, capacity area 4, and wire 5. The insulator is supported by a loop of tarred rope attached to the yardarm, and the capacity area, or wire if it be used direct, is inserted longitudinally in the insulator as as shown. The method illustrated in Fig. 3 was designed by Ducretet and is a superior modification of the one just described.

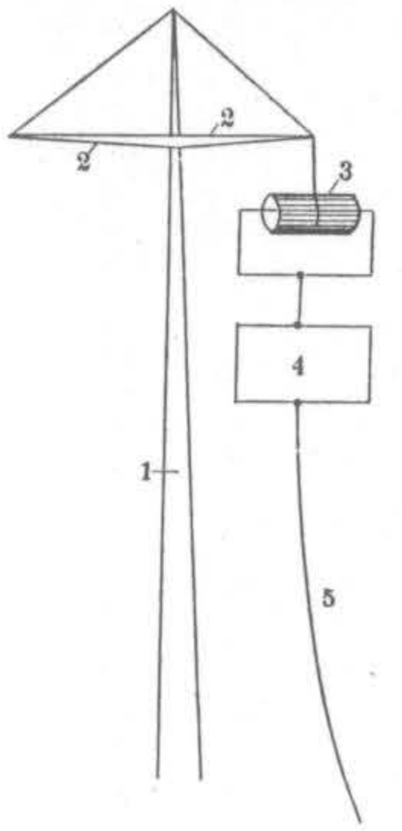

FIG. 2.—METHOD OF SUSPENSION.

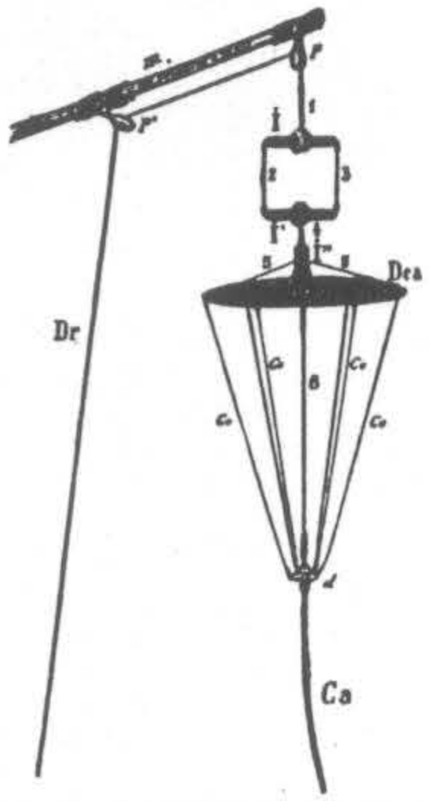

FIG. 3.—DUCRETET METHOD OF SUSPENSION.

A method to eliminate leakage where the aerial wire leads into the station to the instruments is shown in Fig. 4 and is due to Dr. Braun; it will be seen that the leading-in wire passes through a porcelain bushing inserted in an aperture cut in the window-pane.

FORMS OF ORDINARY AERIALS.—The early Popoff antenna consisted of a lightning-rod, while that employed by Marconi in his first essays comprised a single copper wire leading from the instruments and to which a large metal plate was attached to its upper free terminal. Various forms of aerial wires are shown in Fig. 5; the object of adding to the number of wires is to obtain a greater radiating and receptive surface. Referring to the figures, *a* is the ordinary single wire aerial, *b* parallel wires which are in some cases arranged in fan shape, *c* multiple quadrangular aerial, *d* multiple cylindrical aerial, and *e* inverted pyramidal aerial form for long-distance transmission. The length of aerials is from 50 to 200 feet. Fleming has pointed out that if an aerial is composed of seven strands of wire, each having a diameter of No. 22 B. S. G., and a

length of 150 feet, and insulated from the earth. Its capacity, if held vertically, is 0.0003 microfarads. If a number of wires are placed very closely together, their combined capacity is not merely equal

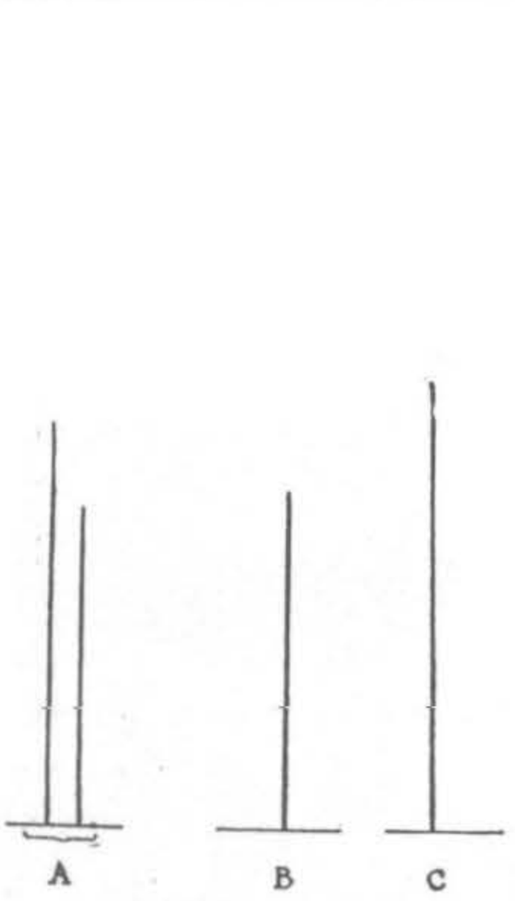

FIG. 7.—DIFFERENTIAL AERIAL SYSTEM OF JEGON.

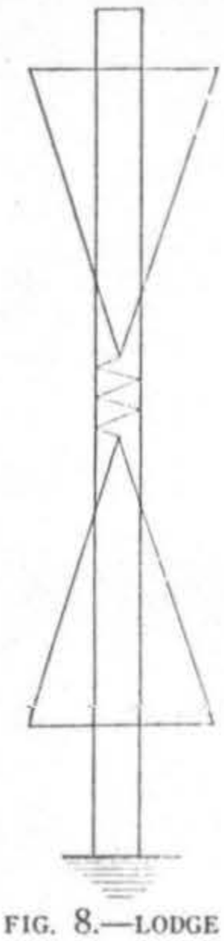

FIG. 8.—LODGE CAPACITY AERIAL

to the sum of their individual capacities[4], and therefore the wires should be placed at a considerable distance apart.

LODGE CAPACITY AERIAL.—The earliest form of aerial, if such it may be termed, for the purpose of selective signaling, is due to Lodge; it is shown in diagram Fig. 8. Two cones of large dimensions, made of metal and insulated from themselves and the earth, served to increase the capacity of the system as well as to indicate and receive the electric wires. The capacity areas were of a definite value, but were connected with an inductance coil so that this factor could be changed.

TOMMASSI JEGON DIFFERENTIAL WIRE AERIAL.—The differential aerial system introduced by Tommassi Jegon some years ago was intended to receive various wave lengths simultaneously by employ-

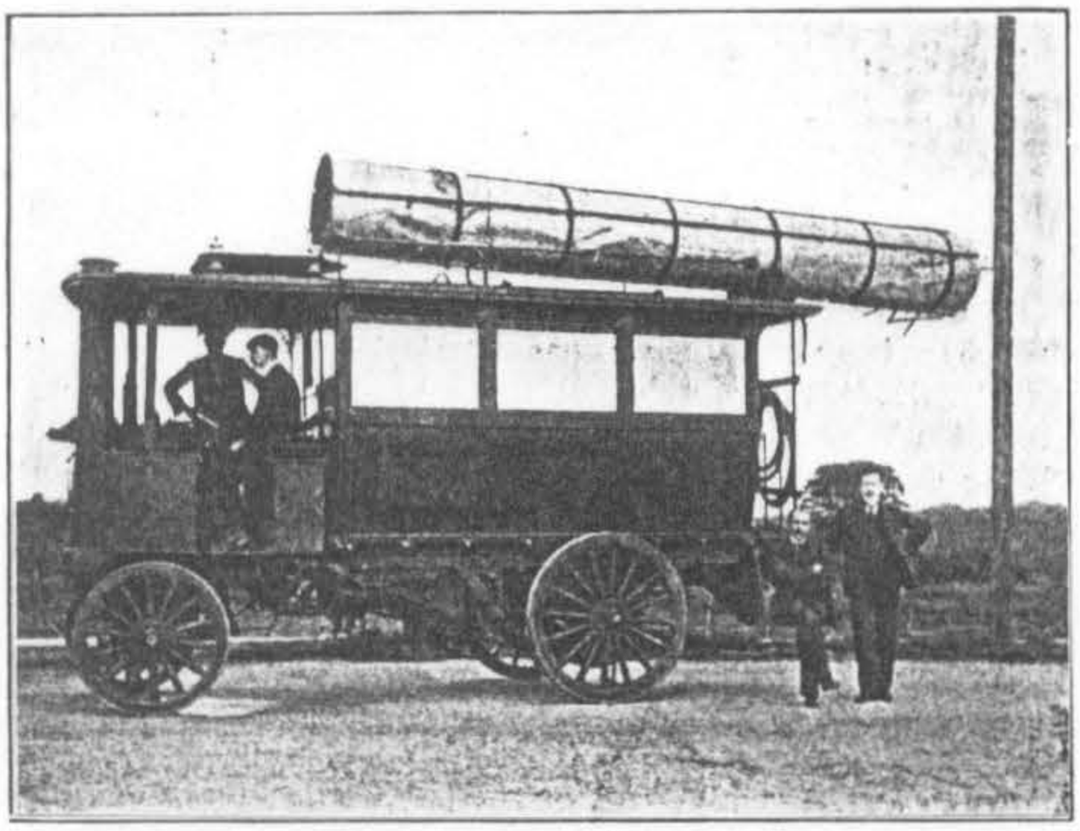

FIG. 9.—MARCONI WIRELESS TELEGRAPH AUTOMOBILE.

ing two or more wires at the transmitting station, as at *A*, Fig. 7; these radiating wires were of different lengths at the receiving station, *B*; 5 km. distant the antenna was equal in length to the shorter one at *A*, while at station *C*, 10 km. distant, the antenna was equal to the longest wire at *A*. By a proper adjustment the indications will not respond except when the shortest wire at *A* is sending to *B* or the longest one at *A* to *C*, except where a definite value of the distance produces a neutral effect on both receivers.

GUARINI SHEATHED AERIAL.—The fact that electric waves are intercepted, reflected and absorbed by metals led Guarini to devise the sheathed aerial shown in Fig. 6; the aerial wires emitting and receiving the waves were insulated and then encased in a metallic sheath diverging at the top, forming a cylinder of large diameter in which a slot was cut; the purpose of this arrangement was to reflect the emitted waves in a given direction or to receive them from a

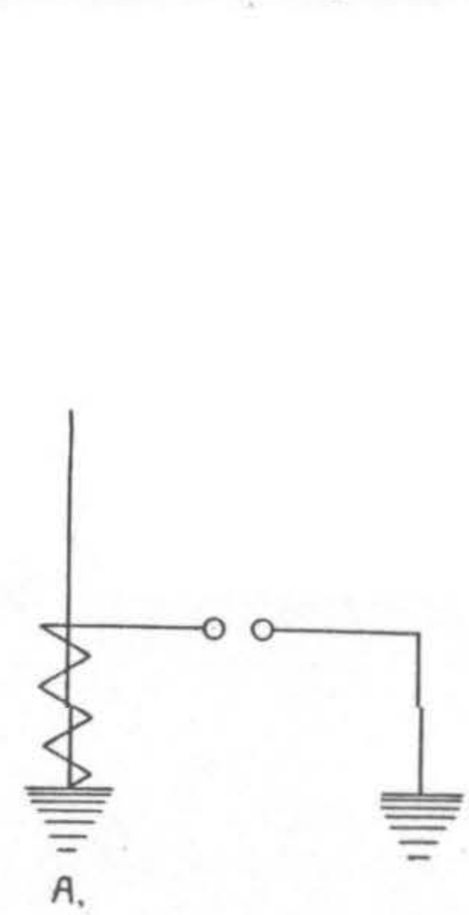

FIG. 10.—SLABY-ARCO DIRECT-EARTHED AERIAL.

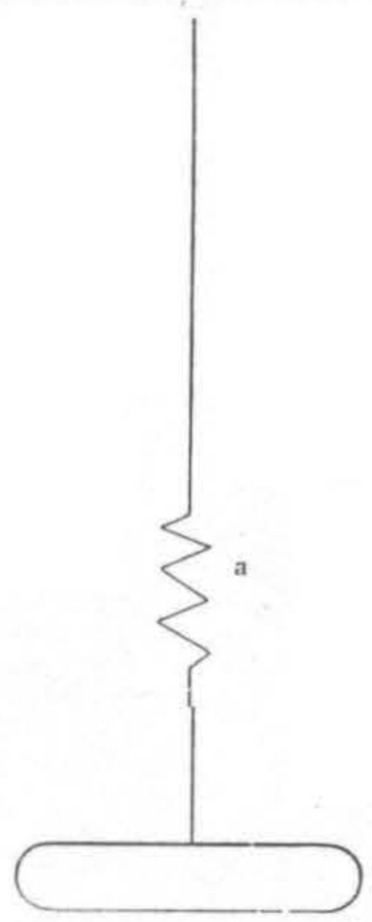

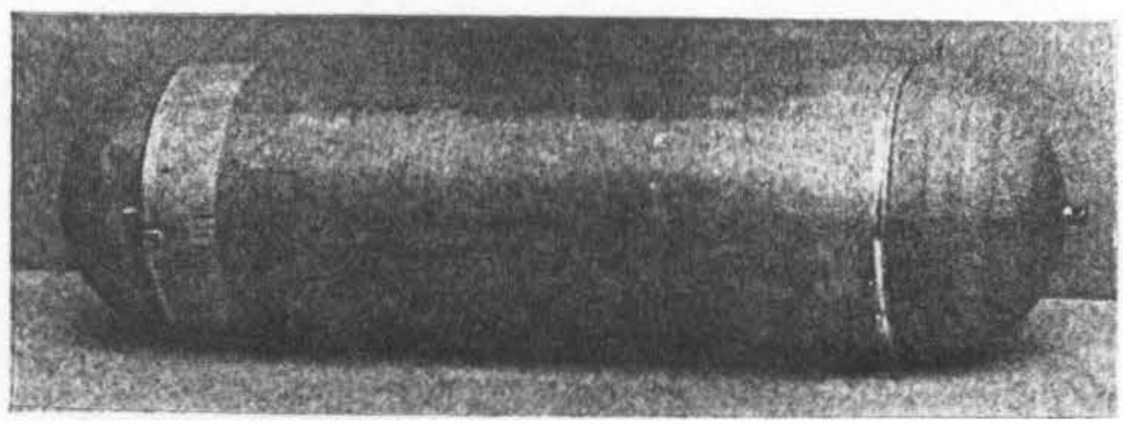

FIG. 11.—BRAUN ARTIFICIAL EARTH.

given point of the compass. There is a very great loss of energy in this method of transmission, but in specific cases it might be useful.

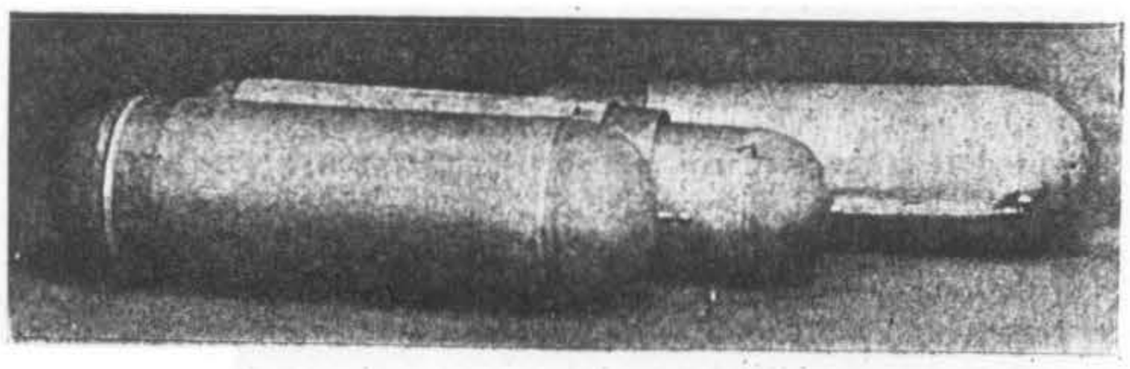

FIG. 12.—BRAUN ARTIFICIAL EARTH.

When receiving all extraneous electric waves are either reflected from the steath surrounding the aerial wire or transformed into oscillations which are conducted to the earth.

MARCONI AERIAL (SECOND FORM).—The aerials employed by Marconi in his first syntonic system, composed of inner and outer metal cylinders, mark the first attempt to eliminate the high vertical wire as a factor in wireless telegraphy. Marconi has used single cylin-

[4]Cantor Lectures, Society of Arts, London, March, 1903.

ders of four or five meters in height in some of his experiments, and it is stated that messages have been sent and received a distance of twenty miles with their aid. A wireless telegraph automobile designed by this inventor for military purposes is equipped with an adjustable cylinder arranged to fold back on top of the vehicle when not in active service. It is illustrated in Fig. 9.

SLABY-ARCO DIRECT EARTHED AERIAL.—To Dr. Slaby and Count Arco is due the credit of having employed the sending and receiving aerials directly connected with the earth. Before the researches which led to this method it was the common practice to connect the lower free end of the aerial wire with one side of the spark-gap or coherer and the earth to the complementary side, but it was subsequently found that if the oscillators and wave detectors were connected to the aerial wire at a point where it found contact with the earth, as in Fig. 10, the potential of the oscillators was equally effec-

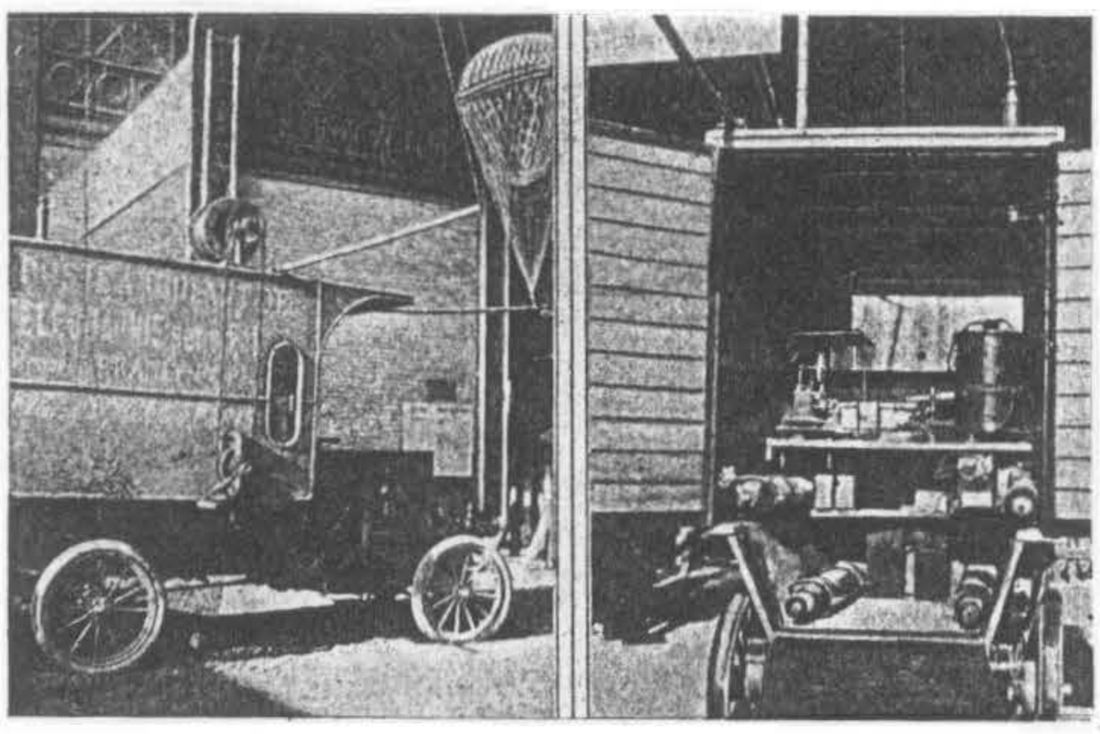

FIG. 14.—BRANLY-POPP WIRELESS TELEGRAPH AUTOMOBILE.

tive, while the discharge of atmospheric through the detector would be dissipated in the earth at *A*. In accordance also with the theory evolved, all waves received by the aerial which were not of a predetermined length will pass into the earth, since the nodal point is at *A;* the aerial wire should be in this case one-fourth the length of the wave it is desired to receive.

BRAUN NON-EARTHED AERIAL.—In Braun's system the radiator, Fig. 11, *A,* is connected with the primary of a transformer coil, *a,* whose opposite terminal is not earth, but is attached to a cylinder of copper or zinc, called an artificial earth, illustrated in the photograph, Fig. 12. This is one of the striking features of the Braun system and an original departure in commercial wireless telegraphy. It is claimed that this method effectually eliminates the disturbances due to atmospheric electricity.

DE FOREST MAST AND AERIAL.—One of the stations of the De Forest system is located at Steeplechase Park, Coney Island. It is equipped with a mast 210 feet in height; it is constructed of four

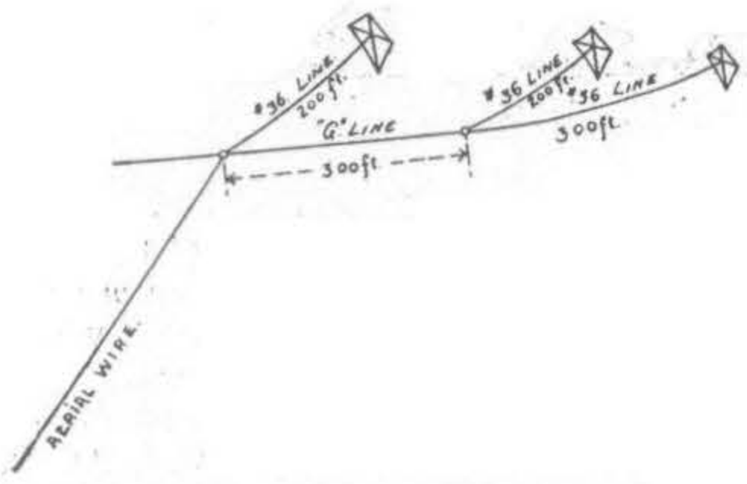

FIG. 15.—AERIAL ATTACHED TO KITES.

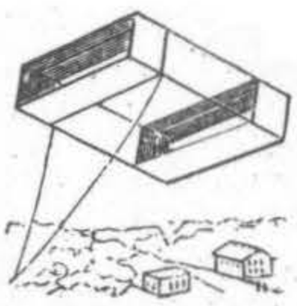

FIG. 16.—BLUE HILL BOX KITE.

poles set in crosstrees and supported by square bars of iron with a shoulder at one end to sustain the topmast over the head of the lower mast. These are termed fids; the mast is guyed to braces sunk into the sand sixteen feet deep. The guys are of wire rope with hemp rope terminals spliced to about 100 feet from the ground; the object of this combination is to maintain the insulation of the aerial cables, of which there are two supported by a yardarm near the top, and to prevent them from coming in contact with the guys.

FESSENDEN WAVE CHUTE.—In a recent patent granted to Prof. Fessenden additional data are given relating to aerials and grounds. This physicist has found it desirable to have a highly conducting surface over which the waves are propagated in the neighborhood of the point where they are generated, and that this highly conducting surface should extend to a distance from the point of their production at least one-fourth of the length of the wave in air and in the direction toward the station to which it is desired to send the

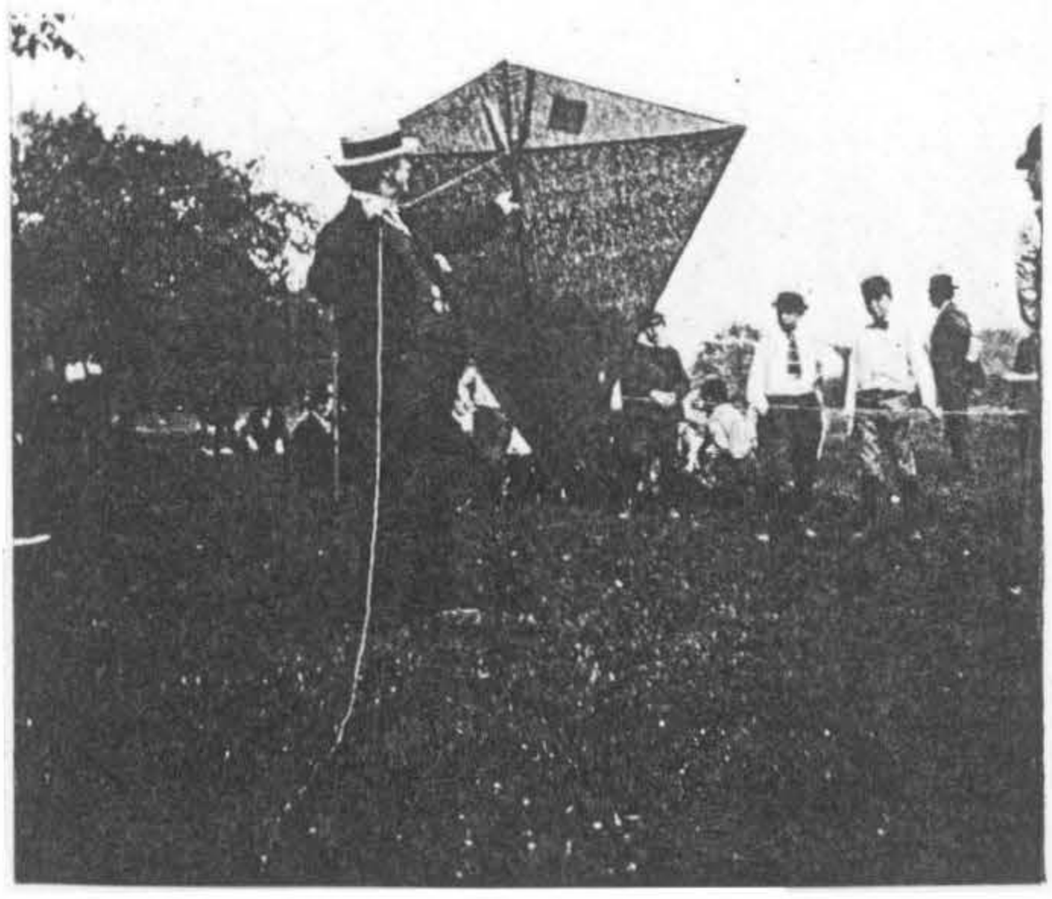

FIG. 17.—MALAY OR EDDY KITE.

message. The diagram, Fig. 13, illustrates the method for producing the desired results and is termed by Fessenden *a wave chute;* in the figure, 1 is the sending conductor, and 2, 2′, 2″ is the grounded conductor leading across building and other obstacles to a $\frac{\gamma}{4}$ beyond the limit of obstructions where the terminals are earthed as shown. The coils 3 and 4, forming guys from the mast, have a period of oscillation different from that of the antenna, and this with the grounded conductor or wave chute eliminates the interference of extraneous waves and serves to dissipate atmospheric potentials which occur in ordinary aerial wire systems. In practice Fessenden employs a sending wire having a large capacity and low inductance. The former is regulated by increasing the area of the

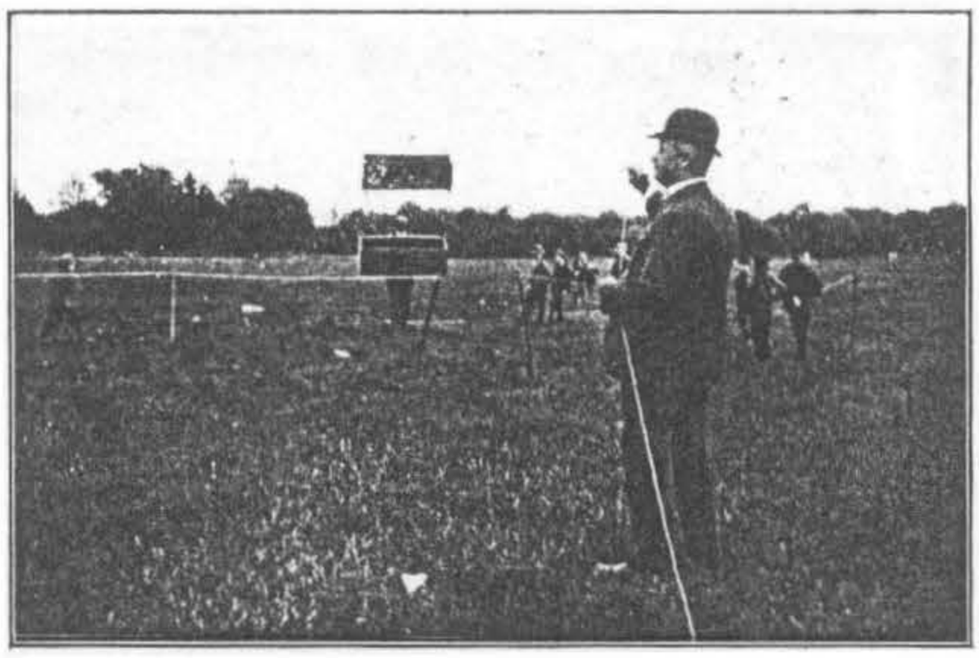

FIG. 18.—BLUE HILL BOX KITE IN FLIGHT.

aerial wire and the latter by adding to the number of turns of wire connecting the vertical wire with oscillator.

KITE-SUSTAINED AERIALS.—With the advent of the auto-coherer and current-actuated detectors came portable transmitters and receptors and the kite-sustained aerial wires. Heretofore one of the greatest obstacles to the successful transmission of wireless messages in military operations was the heavy accoutrements entailed by the use of masts, as these are much too cumbersome to be transported with the facility necessary in such all-important operations, and instruments without 80- or 100-foot aerials are useless. The kite and the balloon offer the solution. Kites are preferable, except in cases when there is no wind, and then small hydrogen gas-bags are useful. In the Branly-Popp wireless telegraph automobile ambulances and balloons are employed. The exterior and interior of these ambulances are reproduced in Fig. 14. Various forms of kites

especially adapted to the velocity of the wind may be obtained for elevating and sustaining the aerial wires. The aerial is attached to the kite as illustrated in Fig. 15. Aluminum wire, in virtue of its extreme lightness, makes a desirable vertical wire for this purpose. The transmitter and receptor utilizes the same vertical wire for radiating and receiving the waves, the change being made by means of an ordinary switch.

FIG. 19.—PORTABLE ARMY EQUIPMENT.

In very light winds the Malay, or, as its improved form is known,

FIG. 20.—INSTRUMENTS IN OPERATION.

the Eddy kite, is largely employed; it is shown in Fig. 17. These kites are fitted with a "bridle," which is already adjusted. To the ring or loop at the center of this bridle the end of the ball of kite-

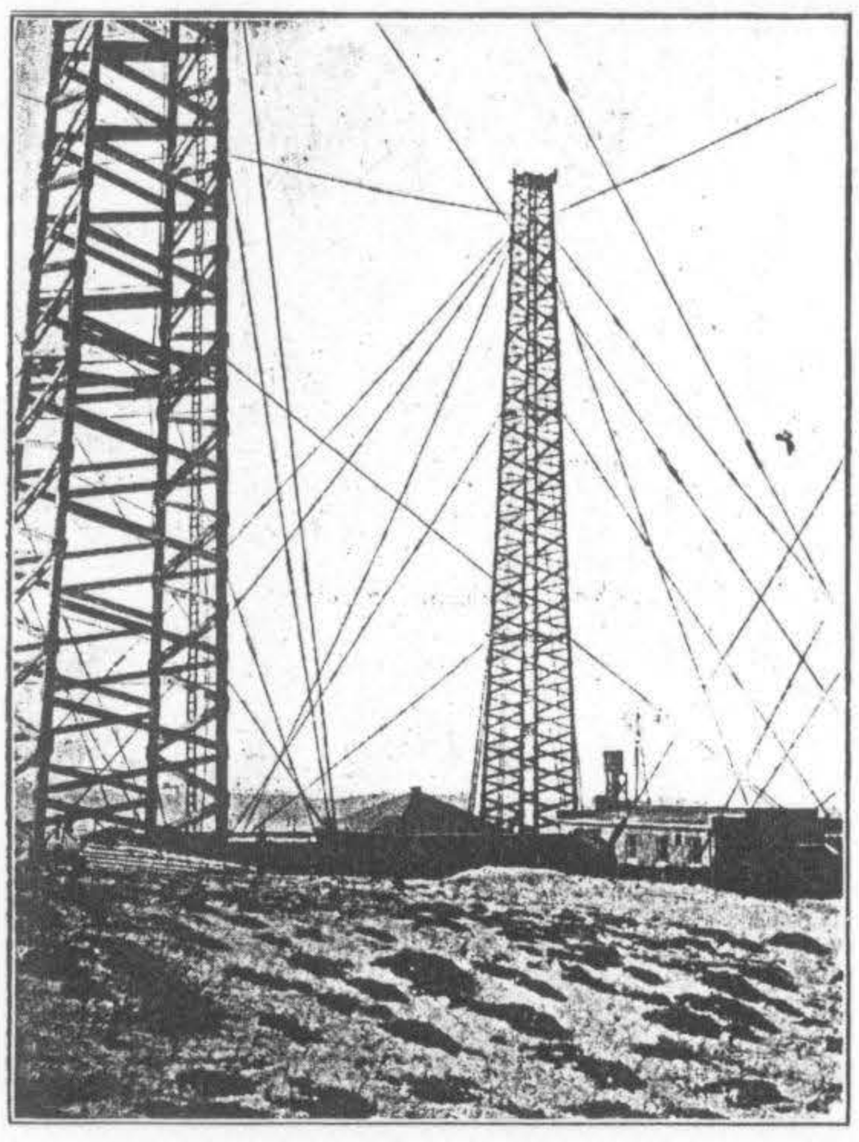

FIG. 21.—MARCONI SOUTH WELLFLEET STATION IN COURSE OF CONSTRUCTION.

cord is secured so that the knot is a firm one. These kites are tailless, may be flown in a very light breeze, and a number of the kites may be connected in tandem and their sustaining properties increased. In winds having a higher velocity the cellular or the American modification of it, known as the Blue Hill box kite, shown in Fig. 17 in outline, and a photographic reproduction in Fig. 18. It has a large sustaining surface and may be used in winds of ordinary velocities; in winds having a velocity of thirty or forty miles per hour a box kite having a very small sustaining surface is especially serviceable, since it possesses marvelous stability. Fig. 19 is a complete portable army equipment constructed by the Braun-Siemens and Halske Company for the German Government; it was placed in charge of the Royal Military Aerostat Battalion; Fig. 20 shows the aerial wire suspended from a kite and the instruments in operation. The transmitting apparatus includes a dynamo direct connected to a gasolene engine and is arranged on one while the receiver is placed on a second gun-carriage.

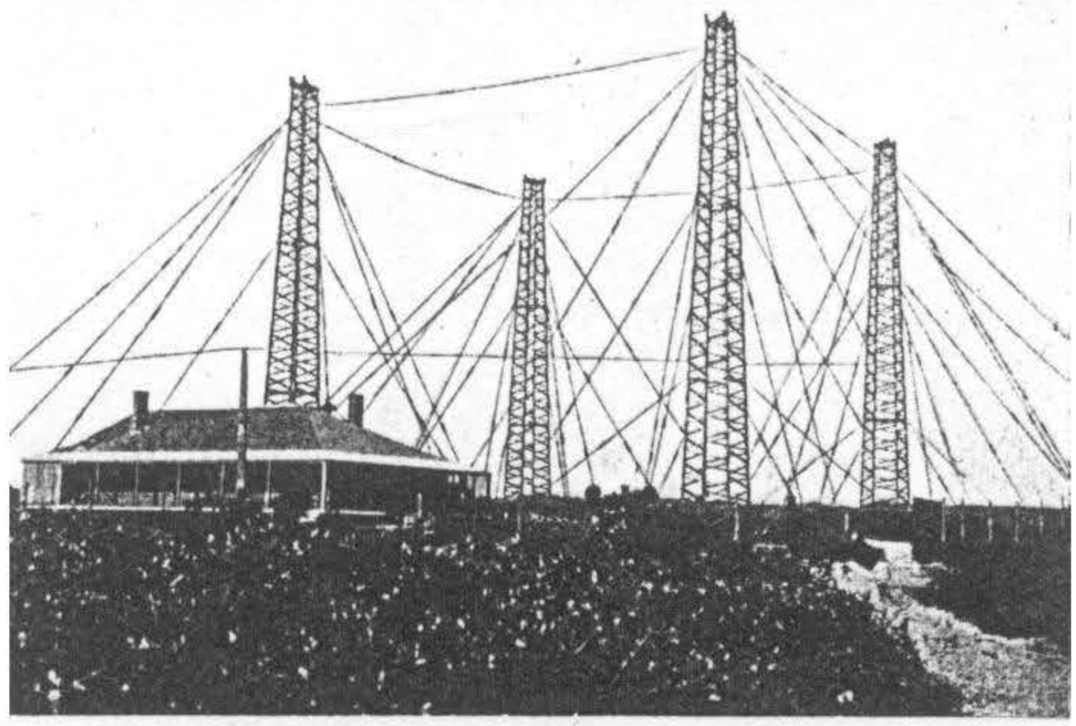

FIG. 22.—SOUTH WELLFLEET STATION IN COURSE OF CONSTRUCTION.

MARCONI CABLELESS STATION AERIAL.—The first transatlantic signals transmitted from the cableless station at Poldhu, England, on December 12, 1901, were received by a single aerial wire suspended from a kite at an elevation of 400 feet at St. Johns, Newfoundland. The kites employed during these aerial tests were constructed on the same general lines as those designed by Major Baden-Powell, consisting of a bamboo frame nine feet in height

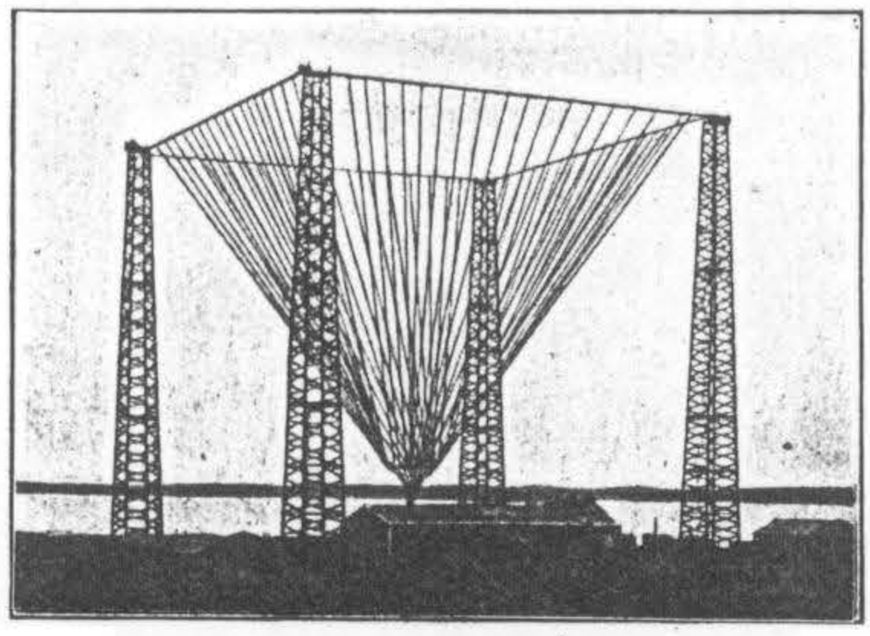

FIG. 23.—WELLFLEET STATION COMPLETED.

covered with silk and having a hexagonal form. The aerial wire passed through a window and was attached to a pole, and from this it led to the kite. The wire leading to earth forming the opposite arm of the resonator was suspended over the cliff from the station at Signal Hill and was connected to heavy plates of copper anchored in the sea. The aerial wires of the transmitting station at Poldhu, England, consisted of 15 vertical wires suspended from masts 210 feet in height and arranged in a circle. The construction of the multiplex aerials at Glace Bay, Nova Scotia, and South Wellfleet, Mass., cableless stations are designed especially for emitting long and powerful electric waves. Figs. 21 and 22 are photographs of the South Wellfleet station in the course of construction; four wooden standards 210 feet in height are arranged in a quadrangle and are sustained by guy wires, appearing as in Fig. 23 when completed; the aerial is composed of 400 wires forming an inverted pyramid; the upper terminals are insulated and the lower ends terminate in a single conductor of large dimensions. The opposite arm of the system is connected with several large metal plates deeply imbedded in the earth to make good contact.

Tesla Currents.

In a paper read before the Bunsen Society at Bonn, Prof. Nernst discusses the fact that it is possible to pass through the body without the least discomfort Tesla currents of a strength which at a much lower frequency would certainly cause death. The explanation hitherto offered has been that the current passed by the surface of the body only. According to Prof. Nernst, however, the explanation is to be found elsewhere; and he maintains that the solution of the problem lies in the fact that the current never lasts sufficiently long in one direction to alter the concentration of the contents of the cell. He finds that changes in concentration vary directly with the strength of the current, and inversely as the square root of the frequency. He has confirmed this hypothesis by an experiment on a frog submitted to a current, the frequency of which could be varied between 100 and 200 cycles per second.

The New York Sun November 1, 1904

THE NEW SUBWAY.

Its Electrical Equipment and System Criticised Severely by Mr. Tesla.

TO THE EDITOR OF THE SUN—*Sir:* I would not disturb the hymn sung by the press in praise of the subway had it not occurred to me that just these few fugitive moments of ecstasy offer the best opportunity for pointing out the necessity of its speedy reequipment. My idea is by no means as odd as it must at first appear to your readers. Permit me to explain.

Electrical power transmission has been my specialty for many years. After the general adoption of my alternating system of distribution, popularly known as the "two, three, multi, or poly phase," I turned my attention exclusively to currents of high tension and devised a scheme of artificial insulation by power, permitting an indefinite extension of the distance of transmission and doing away altogether with the loss in the mains. Finally, through a series of improvements, I arrived at my high potential system, dispensing with wires, in which I have carried the arc of electrical energy transmission well toward its highest technical perfection and capacity of application. These inventions, abolishing all barriers to electrical development, will soon sweep the world with irresistible force.

Naturally enough, I have been intensely interested in this great project, in the city of my home, from its very inception, and have devoted much thought to the best means to employ. The tunnel itself I have never seen and do not know its location. It must be a fine piece of engineering. I am compelled to confess to the same ignorance as regards the power house. The Rapid Transit company has never asked me for any expert advice or suggestion and I have never been invited to examine any part of the work. It is true that my "three phase" system with my "rotary converters" has been adopted, but it is precisely because of this that a change will be necessary in the near future. This combination of alternating and direct current should not have been employed. It represents the state of the art of more than ten years ago. In the power house three phase dynamos are installed. The electro-motive force of the currents is raised by "static transformers." The high tension currents operate in each of the sections of the road a "rotating transformer," in this case one of my three phase synchronous motors having its field excited by and generating direct currents, which in turn, actuate the motors on the cars.

Now, this plan, while operative, is for a great many reasons objectionable, more so in this particular instance. The subway problem was peculiar. The length of the circuits was insignificant. The facilities for placing and insulating the mains were great. Financial limitations, which usually hamper an electrical enterprise, did not exist. There was money to burn. The quickness of travel, the safety of the public and of the adjacent property were the dominating requirements. These have not been properly met. A mistake was made in not asking the electric companies to furnish the best instead of the cheapest equipment.

But it is better to mend late than never. Ignoring the improvements which might be made in the power house, the mains should be insulated artificially by refrigeration. This would save the energy which is now lost in the mains and money besides. More than this, it would insure complete safety against any breakdown of the insulation, which, however, would be self-restorative. The "rotating transformers," introducing many elements of incertitude and danger, should be done away with and "static transformers," if necessary, installed in the sub-stations. Direct currents, which are a constant menace to life and property, despite subdivision, should be most certainly avoided. Motors of this kind, with their brushes and commutators, sparks, copper dust, nitric acid and what not, are not suitable for so important a thoroughfare, and should be replaced by my "induction motors" without brushes and commutators, and perfectly free from the innumerable troubles these devices entail. It would be advisable also to employ a greater number of correspondingly smaller motors on each car. This would be, in my opinion, an entirely safe, economical, and in the long run the cheapest apparatus, which could be taxed, without the slightest risk, in the hours of rush, to its utmost capacity, and which, if properly constructed, should last a century.

To conclude, as I examine the equipment of the subway, I find that about all to be preserved would be Mr. Belmont's beautiful car, this as a *corpus delicti*. The changes suggested will have to be made sooner or later, and I am quite earnest in recommending an immediate appropriation and commencement of this work of reconstruction without delay, else Philadelphia will have an underground railway several decades ahead of ours.

NEW YORK, Oct. 30. N. TESLA.

BOOK TABLE.

EXPERIMENTS WITH ALTERNATE CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY. By Nikola Tesla. New York: McGraw Publishing Company. 1904. Pp. (five by seven inches), ix., 162, with a new portrait of the author and 40 illustrations in the text. Price, $1.

Tesla's is a name to conjure by, and this little book will not lack for readers, although it is but a reprint of a lecture delivered several years ago before the Institution of Electrical Engineers in London and of an article on "The Transmission of Electric Energy Without Wires," published in the Electrical World and Engineer last spring. There is a fascination about the personality and work of Tesla, due partly to his fame as an inventor, but largely to his daring conceptions and prodigal predictions. An example of the latter and of the writer's fervid style is the very last paragraph of the book:

"When the great truth, accidentally revealed and experimentally confirmed, is fully recognized, that this planet, with all its appalling immensity, is to electric currents virtually no more than a small metal ball and that by this fact many possibilities, each baffling imagination and of incalculable consequence, are rendered absolutely sure of accomplishment; when the first plant is inaugurated and it is shown that a telegraphic message, almost as secret and non-interferable as a thought, can be transmitted to any terrestrial distance, the sound of the human voice, with all its intonations and inflections faithfully and instantly reproduced at any other point of the globe, the energy of a waterfall made available for supplying light, heat or motive power anywhere—on sea or land, or high in the air—humanity will be like an ant heap stirred up with a stick. See the excitement coming!"

An interesting biographical sketch forms the introduction to the lecture. In this it is said that Mr. Tesla is "tall and spare, with a clean-cut, thin, refined face and eyes that recall all the stories one has read of keenness of vision and phenomenal ability to see through things."

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Mr. Nicola Tesla, in a communication to a daily paper, criticized the equipment of the New York Subway very unfavorably, which drew forth the following reply from Mr. L. B. Stillwell, the electrical director of the Interborough Company: "My recollection of what Mr. Tesla has done for electrical progress in the past is so vivid that I am disinclined to comment upon his technical suggestions, which perhaps appear more plausible to the average reader than to the engineer. I would suggest to Mr. Tesla, however, that a paper from him containing specific and definite criticism of the electrical equipment of the Subway might be presented before the American Institute of Electrical Engineers, and that if he will present such a paper I shall be glad to meet him upon such an occasion for the purpose of a full and frank discussion."

SUBWAY ELECTRIC TRACTION.

The Views of Mr. Tesla on the Subject Presented and Defended.

TO THE EDITOR OF THE SUN—Sir: My attention has been called to numerous comments on my letter, published in your issue of Nov. 1, and relating to the electrical equipment of the newly opened catacomb in this city. Some of them are based on erroneous assumptions, which it is necessary for me to correct.

When I stated that my system was adopted, I did not mean that I originated every electrical appliance in the subway. For instance, the one which that ill fated electrician was repairing when he was killed, two days after the catacomb was ready for public use, was not invented by me. Nor was that other device on the sidetracked car, which, as will be remembered, caused the burning of two men. I also must deny any connection with that switch or contrivance which was responsible for the premature death of a man immediately afterward, as well as with that other, which cut short the life of his unfortunate successor. None of these funeral devices, I emphatically state, or any of the others which brought on collisions, delays and various troubles and were instrumental in the loss of arms and legs of several victims, are of my invention, nor do they form, in my opinion, necessary appurtenances of an intelligently planned scheme for the propulsion of cars. Referring to these contrivances, it is significant to read in some journals of the 8th inst. that a small firm failed because their bid was too low. This is indicative of keen competition and sharp cutting of prices, and does not seem in keeping with the munificence claimed for the Interborough company.

I merely intended to say in my letter that my system of power transmission with three-phase generators and synchronous motor converters was adopted in the subway, the same as on the elevated road. I devised it many years ago for the express purpose of meeting the varied wants of a general electrical distribution of light and power. It has been extensively introduced all over the world because of its great flexibility, and under such conditions of use has been found of great value. But the idea of employing in this great city's main artery in a case presenting such rigid requirements, this flexible system, offering innumerable chances for breakdowns, accidents and injuries to life and property, is altogether too absurd to dignify it with any serious comment. Here only my multiphase system, with induction motors and closed coil armatures—apparatus unfailing in its operation and minimizing the dangers of travel should have been installed. Nothing, not even ignorance, will prevent its ultimate adoption; and the sooner the change is made the better it will be for all concerned. Personally I have no financial or other interest in the matter, except that as a long resident of this city I would have been glad to see my inventions properly used to the advantage of the community. Under the circumstances I must forego this gratification.

The consequences of the unpardonable mistake of the Interborough company are not confined to this first subway or even to this city. We are driven to travel underground. The elevated road is the eighth world wonder, as colossal and imposing in the feature of public forbearance as the Pyramid of Cheops in its dimensions. Sooner or later all interurban railways must be transformed into subterranean. This will call for immense investments of capital, and if defective electrical apparatus is generally adopted the damage to life and property will be incalculable, not to speak of inconvenience to the public.

It seems proper for me to acknowledge on this occasion the painstaking suggestions of some friends of mine, mostly unknown to me, both in the large domain of electrical achievement and in the small sphere of my friendship, to again address the American Institute. It is customary with scientific men to present an original subject only once. I have done so and do not desire to depart from this established precedent. A lecture on the defects of the subway offers great opportunities, but would not be original. In view of certain insinuations I may cite a recently published statement of Mr. C. F. Scott, formerly president of the American Institute: "As a matter of history it is the Tesla principle and the Tesla system which have been the directing factors in modern electrical engineering practice." There are but a few men whose acknowledgment of my own work I would quote. Mr. Scott is one of them, as the man whose cooperation was most efficient in bringing about the great industrial revolution through these inventions. But the suggestions of my good friends have fallen on fruitful ground, and should it be possible for me to spare time and energy I may ask the city authorities for power to investigate the subway and make a sworn report to them on all the defects and deficiencies I may discover, in the interest of public welfare.

A few more words in relation to the signs. With all due respect to general opinion, I entertain quite a different view on that subject. Advertising is a useful art, which is being lifted continually to a higher plane and will soon be quite respectable. It should not be hampered, but rather encouraged. I would give the Interborough company every facility for exploiting it, restricting it only in so far as the artistic execution is concerned. A commission of capable men, comprising a painter, a sculptor, an architect, a literary man, an engineer and an executive business man, might be appointed, to pass upon the merits of the signs submitted for acceptance. I do not see why the public should object to them if they were regulated in this manner. They will further business, make travel less tedious and help many skilful artisans. The subways are bound to become municipal property, and the city will then derive a revenue from them. What is most important for the safety of life and property, quickness and security of travel, should be first considered. All this depends on the electrical equipment. The engineers have built a good tunnel, and proper apparatus should be installed to match it.

NEW YORK, Nov. 26. NIKOLA TESLA.

TESLA'S CAUSTIC LETTER.

The following communication from Mr. Nikola Tesla appeared in the New York *Sun* November 27:

"My attention has been called to numerous comments on my letter, published in your issue of November 1, and relating to the electrical equipment of the newly opened catacomb in this city. Some of them are based on erroneous assumptions, which it is necessary for me to correct.

"When I stated that my system was adopted, I did not mean that I originated every electrical appliance in the subway. For instance, the one which that ill-fated electrician was repairing when he was killed, two days after the catacomb was ready for public use, was not invented by me. Nor was that other device on the sidetracked car, which, as will be remembered, caused the burning of two men. I also must deny any connection with that switch or contrivance which was responsible for the premature death of a man immediately afterward, as well as with that other, which cut short the life of his unfortunate successor. None of these funeral devices, I emphatically state, or any of the others which brought on collisions, delays and various troubles and were instrumental in the loss of arms and legs of several victims, are of my invention, nor do they form, in my opinion, necessary appurtenances of an intelligently planned scheme for the propulsion of cars. Referring to these contrivances, it is significant to read in some journals of the 8th inst. that a small firm failed because their bid was too low. This is indicative of keen competition and sharp cutting of prices, and does not seem in keeping with the munificence claimed for the Interborough Company.

"I merely intended to say in my letter that my system of power transmission with three-phase generators and synchronous motor converters was adopted in the subway, the same as on the elevated road. I devised it many years ago for the express purpose of meeting the varied wants of a general electrical distribution of light and power. It has been extensively introduced all over the world because of its great flexibility, and under such conditions of use has been found of great value. But the idea of employing in this great city's main artery, in a case presenting such rigid requirements, this flexible system, offering innumerable chances for breakdowns, accidents and injuries to life and property, is altogether too absurd to dignify it with any serious comment. Here only my multiphase system, with induction motors and closed coil armatures—apparatus unfailing in its operation and minimizing the dangers of travel—should have been installed. Nothing, not even ignorance, will prevent its ultimate adoption; and the sooner the change is made the better it will be for all concerned. Personally, I have no financial or other interest in the matter, except that as a long resident of this city I would have been glad to see my inventions properly used to the advantage of the community. Under the circumstances I must forego this gratification.

"The consequences of the unpardonable mistake of the Interborough Company are not confined to this first subway or even to this city. We are driven to travel underground. The elevated road is the eighth world wonder, as colossal and imposing in the feature of public forbearance as the Pyramid of Cheops in its dimensions Sooner or later all interurban railways must be transformed into subterranean. This will call for immense investments of capital, and if defective electrical apparatus is generally adopted the damage to life and property will be incalculable, not to speak of inconvenience to the public.

"It seems proper for me to acknowledge on this occasion the painstaking suggestions of some friends of mine, mostly unknown to me, both in the large domain of electrical achievement and in the small sphere of my friendship, to again address the American Institute. It is customary with scientific men to present an original subject only once. I have done so and do not desire to depart from this established precedent. A lecture on the defects of the subway offers great opportunities, but would not be original. In view of certain insinuations I may cite a recently published statement of Mr. C. F. Scott, formerly president of the American Institute: 'As a matter of history it is the Tesla principle and the Tesla system which have been the directing factors in modern electrical engineering practice.' There are but a few men whose acknowledgment of my own work I would quote. Mr. Scott is one of them, as the man whose co-operation was most efficient in bringing about the great industrial revolution through these inventions. But the suggestions of my good friends have fallen on fruitful ground, and should it be possible for me to spare time and energy I may ask the city authorities for power to investigate the subway, and make a sworn report to them on all the defects and deficiencies I may discover, in the interest of public welfare.

"A few more words in relation to the signs. With all due respect to general opinion, I entertain quite a different view on that subject. Advertising is a useful art, which is being lifted continually to a higher plane, and will soon be quite respectable. It should not be hampered, but rather encouraged. I would give the Interborough Company every facility for exploiting it, restricting it only in so far as the artistic execution is concerned. I do not see why the public should object to them if they were regulated in this manner. They will further business, make travel less tedious, and help many skillful artisans. The subways are bound to become

municipal property, and the city will then derive a revenue from them. What is most important for the safety of life and property, quickness and security of travel, should be first considered. All this depends on the electrical equipment. The engineers have built a good tunnel, and proper apparatus should be installed to match it. NIKOLA TESLA.

"New York. Nov. 26."

Design for an Edison Medal.

A meeting of the jury in the matter of a competition for the selection of a design for an Edison medal commemorating the invention of the incandescent lamp, under the auspices of the National Sculpture Society, was held recently at the studio of Mr. J. Q. A. Ward, New York City.

Those present were J. Q. A. Ward, chairman, Daniel C. French, Augustus Saint Gaudens, for the National Sculpture Society; Edward D. Adams and T. C. Martin, for the Edison Medal Association and on behalf of the American Institute of Electrical Engineers.

After a further examination of the 29 designs submitted in competition, the committee by unanimous action, awarded the first prize of $1,000 for the successful design, including its execution in such shape and detail as will permit direct reduction to medal size, to Mr. James Earl Fraser. The second prise of $100 to Mr. Adolph A. Weinman, and the third prize of $50 to Miss Evelyn B. Longman. The successful competitor, Mr. Fraser, has been requested to develop his design for final consideration by the committee.

Supreme Court Action on Tesla Split-Phase Patents.

On Monday, November 28, the United States Supreme Court denied a petition for a writ of certiorari directing the United States Court of Appeals for the First Circuit to certify a case tried by that court for review by the Supreme Court. The petitioner was the Stanley Instrument Company and the respondent the Westinghouse Electric & Manufacturing Company.

The patents in suit were the Tesla patents, Nos. 511,559 and 511,560, granted December 26, 1893, and commonly known as the Tesla split-phase patents. The first stage of the litigation ended March 11, 1903, when Judge Colt, of the Massachusetts Circuit Court, declared the patents invalid owing to a publication in an Italian journal dated April 22, 1888, of a lecture by Ferraris. The case was then carried to the Circuit Court of Appeals and on September 9, 1904, that court decided that sufficient proof had been presented to show that Tesla had made the invention involved prior to the date of the Ferraris publication.

The principal contention for a review of the case by the Supreme Court was that the Circuit Court of Appeals for the Second Circuit had decided in an opinion dated February 25, 1903, that the said patents were invalid on the grounds of the Ferraris anticipation, and that the decisions of the Courts of Appeal of the First and Second Districts were at variance and conflict with each other, and that the error of one or the other could only be authoritatively corrected by the Supreme Court. The respondents in answer to this contention held that the alleged divergence between the courts relates only to the sufficiency of the Tesla proofs as contained in the two records, on a question of fact; that the two courts had before them substantially different records, and therefore there was no "conflict" and the case consequently was not appropriate for certiorari.

Advertising Almost Respectable.

In a recent letter to the New York Sun Mr. Tesla spoke, among other features of the New York subway, of the advertising signs that have been criticized. He made this curiously worded statement: "A few more words in relation to the signs. With all due respect to general opinion, I entertain quite a different view on that subject. Advertising is a useful art, which is being lifted continually to a higher plane, and will soon be quite respectable. It should not be hampered, but rather encouraged. I would give the Interborough company every facility for exploiting it, restricting it only in so far as the artistic execution is concerned."

Wonderful Discoveries in Electricity

ELECTRICAL FORCE WITHOUT WIRES

Nikola Tesla Talks of His Wonderful Discoveries in Transmitting Energy.

THE INVENTOR'S QUEER MIND

Expects to Send Force and Intelligence Around the World Sans Cable.

By FRANK G. CARPENTER.

[*Special Letter to The Dispatch.*]

NEW YORK, Dec. 17.—I give you today the substance of two remarkable talks with Nikola Tesla. The first I had in his laboratory on East Houston street nine years ago last September. The second was held in the Waldorf to-night.

The first interview was most interesting, giving a wonderful insight into Tesla the inventor and Tesla the man, but it was never published, for Mr. Tesla, at its close, on the ground of business reasons, begged that I say nothing about him for months to come. I wrote out the notes, however, and laid them away, and when I met Mr. Tesla to-night I told him I now intended to use them. At the same time we had the extraordinary conversation about his recent discoveries and inventions as to the transmission of force, which I reproduce in the latter part of this article.

Tesla the Man.

First take a glance at Tesla the man. He looked more like an Italian savant than a hard-working inventor when I saw him in the Waldorf to-night. He was in evening dress and was the most striking figure of the score of public men who stood about the lobby. Mr. Tesla is now 47 years of age and is in his physical and intellectual prime. He is tall and slender, his head is long, thin and intellectual, with a forehead high and full. He was born in Hungary and educated there, but he speaks English perfectly and is one of the most charming conversationalists I have ever met.

During my chat of some years ago he talked of his boyhood. His father was a clergyman of the Greek Church, and Nikola was intended for the priesthood. He had a brother older than himself, whom the rest of the family considered much brighter. That brother died young, and this so crazed his father and mother that it took them long to realize the genius of Nikola. If he stood well in his studies his father's eyes would fill as he thought how much better, perhaps, the other son might have done, and whatever Nikola did was always compared with the possible work of the boy who had passed away. His first education was in the public schools of Gospich, and after that he went to the Real Schule at Karlstadt. As he went on with his studies he liked mathematics so much that he intended to fit himself to be a professor of mathematics and physics, and with that view studied at the Polytechnic School at Gratz. He changed to the engineering course, and later on studied philosophy and languages in the colleges at Prague and Budapest. He has since been made a doctor of laws by Yale and Columbia.

Shortly after completing his studies Mr. Tesla was associated with the Government of Austria-Hungary in the telegraph engineering department, where he invented several improvements. From there he went to Paris to be eingineer of a large lighting company, and thence to the United States, where he was employed by Thomas Edison in his laboratory. His next position was that of electrician to the Tesla Electric Light Company, and at the same time he established the Tesla laboratory here, from which his great inventions have come.

Tesla the Inventor.

During my chat with Mr. Tesla I asked him when he first realized that he had the inventive faculty and he told me he had always been inventing something or other. When he was quite a small boy he made toy guns, which would shoot birds, and as he was the only one who could make them he supplied the boys of his neighborhood. He made clocks at 8 or 9 years and began to dabble in electricity before he was in his teens. His first determination to devote his life to invention came shortly after he went to London to deliver a lecture before a scientific society there. At this lecture he met Lord Rayleigh, the great physicist, and showed him some of his experiments. Rayleigh said that he had undoubtedly the faculty of discovery and that he would succeed as an inventor.

"Shortly after this my mother died," said Mr. Tesla, "and I concluded to exert this faculty. Lord Rayleigh had said I possessed it and upon examining myself I believed him correct. I did not want to waste my powers on small things and I decided to strive toward something that would benefit humanity. I am working on an invention for the transmission of force. This invention will, I believe, revolutionize the world of labor. I am also working on electricity and I cannot remember when I was not working more or less in the direction of a successful flying machine. My idea as to that is along different lines than any yet proposed and I expect to see it realized. Indeed, we shall eventually have flying machines that will be large enough to carry crowds through the air. They must be large in order to succeed."

TESLA IN HIS WORKSHOP.

These words were uttered by Mr. Tesla nine years ago. To-day he says he has completed his force transmission invention, as will be seen by my Waldorf conversation, which follows. He has also done other things which he proposed in that interview. Remember it was before the time of the wireless telegraph, but he then said to me the following:

"I tell you, we are on the threshold of a new era. We have only begun to master the great forces of nature, and the inventions of the next few decades will be far superior to any of the past. What would you think of standing on the shore and telephoning to your friends in midocean? What of being in the center of a room and making your whole body blaze with light? What of sending power to and fro over the earth at will and making it do its work anywhere and almost anyhow?"

How Tesla Works.

As to Mr. Tesla himself, there is no harder worker known. He told me that he seldom slept more than four hours of a night, and during some periods not more than three. When in the thick of a new invention it is hard to sleep. His work is always with him and he says that his mind sometimes works in his sleep. He awakens in the morning to find that the problem which had worried him when he went to bed has been practically sloved over night. He has always been a light sleeper. His mother died at 70 and she never took more than four hours' sleep. His father was a light sleeper.

Tesla is a peculiar worker. Failures do not trouble him. After he undertakes a thing and decides that it should come out a certain way he keeps on experimenting and experimenting, believing in his success. He says that if he doubted his ability it would make him crazy. He seems to have a dual mind. He told me that he often found himself carrying on two trains of thought at the same time, and said that while he was talking to me he could see the figures of some of his calculations behind me and could carry them on at the same time. He is always figuring. His scrap basket is filled with the calculations which he has torn up and thrown away. He keeps a record of his experiments, and when his laboratory burned some years ago he lost the work of years in ideas and suggestions which had been thus recorded.

Tesla's New Inventions.

And now to Mr. Tesla's latest discoveries. If he has what he thinks he has he will revolutionize labor and give man greater benefits than have come from any inventor since the world began. Indeed, the statements made me to-night in the mouth of any other man would be a fair test of insanity. But many of Tesla's wild statements of the past have been verified by great working inventions. He said he could harness Niagara, and through his experiments in the rotary magnetic fields Niagara is now furnishing a power equal to that of tens of thousands of horses, and electrical works are being run by the same principle all over the globe. The New York subway, for instance, is founded upon it. Tesla demonstrated that wireless telegraphy could be done in 1893, and it is a question whether his inventions in that field are not prior to those of Marconi or De Forrest.

To-night he told me that he had almost completed inventions by which he could send electrical power to any distance without wires, and that in any quantity, small or great. Said he:

"I have proved that power can be thus transmitted. Let us suppose I have my plant at Niagara and you are running a sugar factory in Australia; by my discoveries it will be possible to send you 100, 500 or 1,000 horse-power for your factory, and to supply the same regularity by the force furnished from Niagara Falls. Suppose you are traveling in the wilds of the Andes and make your camp on the shores of Lake Titicaca. By the outcome of this principle you may have telegraphed to you there instantaneous reports of the news of the world as it happens from time to time. You may cook your dinner over an electric fire thus transmitted, and you may have the same at will on any part of the globe. We shall be able to send power from place to place at will, and that at such a small cost that it will be industrially profitable."

The Transmission Energy

"How did you discover that this might be done, Mr. Tesla?" I asked.

"I have for years been working on the transmission of electrical energy, and in 1898 established a laboratory on the edge of the Rock mountains near Colorado Springs. My laboratory there was over 6,000 feet high, higher than the top of Mount Washington, and I had extraordinary conditions for my experiments. Colorado is famous for its natural displays of electrical force. The earth at times is alive with electrical vibrations and the air is full of electricity. I have seen 12,000 lightning discharges within two hours and all within a radius of 30 miles of my laboratory. These discharges were of great violence, some of them looking like trees of fire on the heavens. It was among such discharges that I had my electrical transmission through the earth and air. One day while watching the lightning I noticed that the discharges afar off often affected the instruments in my laboratory more than those near by. Upon examination I found that this could not be caused by the difference of intensity in the individual discharges.

"What could it be?

"Through instruments made for the purpose I tested the matter from time to time and finally came to the conclusion that the vibrations caused by the lightning moved around the world and that there were stationary waves. I could gauge the discharges near the laboratory and see them fade away and after a certain fixed period find them returning with almost no loss of power. In short, this planet, as big as it is, was acting as a conductor, and I became convinced that upon it not only telegraphic messages, but also the modulations of the human voice and electrical power in unlimited amounts could be carried around the entire globe and sent to any part of it with hardly any perceptible loss. With my transmitter I actually sent electrical vibrations around the world and received them again, and I then went on to develop my machinery. I had, as I have told you, been studying and inventing along the lines of electrical transmission and was ready to take advantage of my discovery. I have since so improved the means of individualization and isolation that such energy may be sent in any amount to any fixed place without danger of its going elsewhere or affecting others, and I believe the individualization can be carried out to almost any degree."

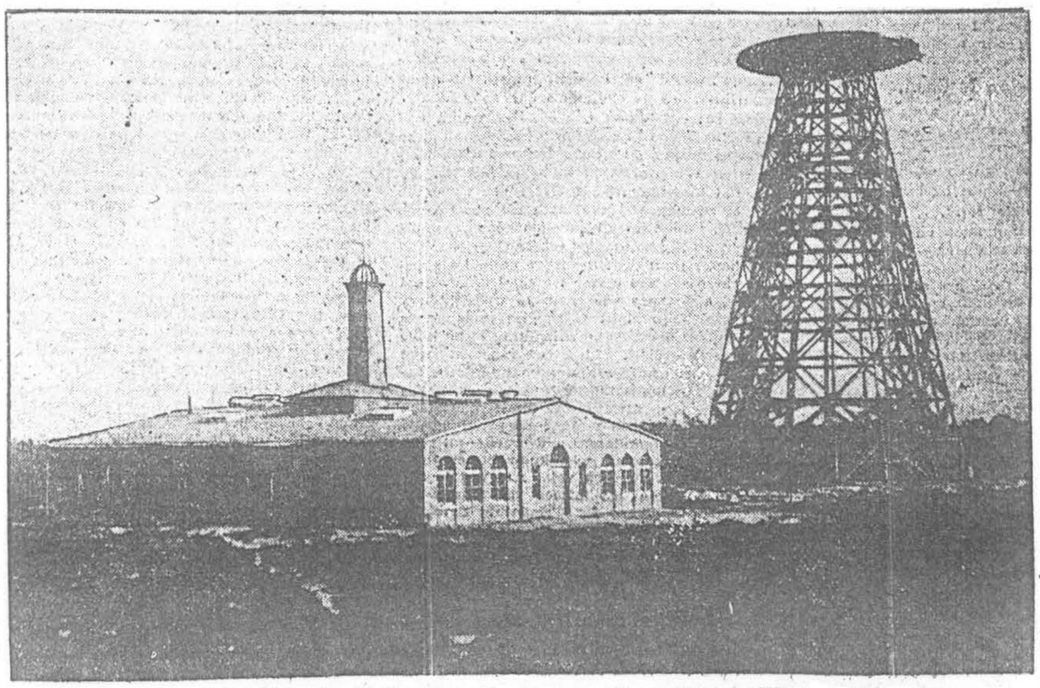
Niagara for the World.

"Will this enable the power of Niagara to be sent anywhere over the world?"

"Yes. I have been experimenting at my laboratory on Long Island. I have machinery and buildings there which have cost in the neighborhood of $350,000, and the results show me that a plant could be erected at Niagara which can transmit its force to any place desired. I am designing such a plant now at my laboratory, and would have had it completed had it not been for unforeseen delays, which have nothing to do with its technical features. The design which I have adopted will have a transmitter which will emit a wave complex of a total maximum activity of 10,000,000-horse power, 1 per cent of which is enough to girdle the globe. This enormous rate of energy delivery—it is twice as much as the force of Niagara Falls—is obtainable only by the use of certain artifices which I shall make known some time in the future.

"We have been offered 10,000-horse power from the Canadian Power Company. What I want to do is to build machinery there and transmit this power to different parts of the globe. The value of that amount of horse power would be about $200,000 per year, and a plant erected to take advantage of it will pay large dividends."

"How much would the plant cost?"



"It might cost in the neighborhood of $2,000,000, but its value would be enormous, and its success would revolutionize the working forces of the globe. It would result in other plants being erected otherwheres and in the utilization of all the great waterfalls for the work of man."

"By this invention every live part of Mother Earth's body would be brought into action. Energy will be collected all over the globe in amounts small or large, as it may exist, ranging from a fraction of one to a few horse power or more. Every water fall can be utilized, every coal field made to produce energy to be transmitted to vast distances, and every place on earth can have power at small cost. One of the minor uses might be the illumination of isolated homes. We could light houses all over the country by means of vacuum tubes operated by high frequency currents. We could keep the clocks of the United States going and give every one exact time; we could turn factories, machine shops and mills, small or large, anywhere, and I believe could also navigate the air.

The Transmission of Intelligence.

"One of the most important features of this invention," said Mr. Tesla, "will be the transmission of intelligence. It will convert the entire earth into a huge brain, capable of responding in every one of its parts. By the employment of a number of plants, each of which can transmit signals to all parts of the world, the news of the globe will be flashed to all points. A cheap and simple receiving device, which might be carried in one's pocket, can be set up anywhere on sea or land, and it will record the world's news as it occurs, or take such special messages as are intended for it. If you are in the heart of Sahara your wife can telegraph to you from Washington, and if the instrument is properly made you alone will get the message. A single plant of a few horse power could operate hundreds of such instruments, so that the invention has an infinite working capacity and will cheapen the transmission of all kinds of intelligence."

THE TESLA POWER PLANT FOR TRANSMITTING FORCE WITHOUT WIRES.

A TALK WITH NIKOLA TESLA

Written for The State.

Copyright, 1904, by Frank G. Carpenter.

New York, Dec. 17.—I give you today the substance of two remarkable talks with Nikola Tesla. The first I had in his laboratory on east Houston street nine years ago last September. The second was held in the Waldorf tonight.

The first interview was most interesting, giving a wonderful insight into Tesla the inventor and Tesla the man, but it was never published, for Mr. Tesla at its close, for business reasons, begged that I say nothing about him for months to come. I wrote out the notes, however, and laid them away, and when I met Mr. Tesla tonight I told him I now intended to use them. At the same time we had the extraordinary conversation about his recent discoveries and inventions as to the transmission of force, which I reproduce in the latter part of this article.

TESLA THE MAN.

First take a glance at Tesla the man. He looked more like an Italian savant than a hard working inventor when I saw him in the Waldorf tonight. He was in evening dress and was the most striking figure of the score of public men who stood about the lobby. Mr. Tesla is now 47 years of age and is in his physical and intellectual prime. He is tall and slender, his head is long, thin and intellectual, with a forehead high and full. He was born in Hungary and educated there, but he speaks English perfectly and is one of the most charming conversationalists I have ever met.

During my chat of some years ago he talked of his boyhood. His father was a clergyman of the Greek church, and Nikola was intended for the priesthood. He had a brother older than himself, whom the rest of the family considered much brighter. That brother died young, and this so crazed his father and mother that it took them long to realize the genius of Nikola. If he stood well in his studies his father's eyes would fill as he thought how much better, perhaps, the other son might have done, and whatever Nikola did was always compared with the possible work of the boy who had passed away. His first education was in the public schools of Gospich, and after that he went to the Real Schule at Karlstadt. As he went on with his studies he liked mathematics so much that he intended to fit himself to be a professor of mathematics and physics, and with that view studied at the polytechnic school at Gratz. He changed to the engeering course, and later on studied philosophy and languages in the colleges at Prague and Budapest. He has since been made a doctor of laws by Yale and Columbia.

Shortly after completing his studies Mr. Tesla was associated with the government of Austria-Hungary in the telegraph engineering department, where he invented several improvements. From there he went to Paris to be engineer of a large lightning company, and thence to the United States, where he was employed by Thomas Edison in his laboratory. His next position was that of electrician to the Tesla Electric Light company, and at the same time he established the Tesla laboratory here, from which his great inventions have come.

TESLA THE INVENTOR.

During my chat with Mr. Tesla I asked him when he first realized that he had the inventive faculty and he told me he had always been inventing something or other. When he was quite a small boy he made toy guns, which would shoot birds, and as he was the only one who could make them he supplied the boys of his neighborhood. He made clocks at eight or nine years and began to dabble in electricity before he was in his teens. His first determination to devote his life to invention came shortly after he went to London to deliver a lecture before a scientific society there. At this lecture he met Lord Rayleigh, the great physicist, and showed him some of the experiments. Rayleigh said that he had, undoubtedly, the faculty of discovery and that he would succeed as an inventor.

"Shortly after this my mother died," said Mr. Tesla, "and I concluded to exert this faculty. Lord Rayleigh had said I possessed it and, upon examining myself, I believed him correct. I did not want to waste my powers on small things and I decided to strive toward something that would benefit humanity. I am working on an invention for the transmission of force. This invention will, I believe, revolutionize the world of labor. I am also working on electricity and I cannot remember when I was not working more or less in the direction of a successful flying machine. My idea, as to that, is along different lines than any yet proposed and I expect to see it realized. Indeed, we shall eventually have flying machines that will be large enough to carry crowds through the air. They must be large in order to succeed."

These words were uttered by Mr. Tesla nine years ago. Today he says he has completed his force transmission invention, as will be seen by my Waldorf conversation, which follows. He has also done other things which he proposed in that interview. Remember it was before the time of the wireless telegraph, but he then said to me the following:

"I tell you, we are on the threshold of a new era. We have only begun to master the great forces of nature, and the inventions of the next few decades will be far superior to any of the past. What would you think of standing on the shore and telephoning to your friends in midocean? What of being in the centre of a room and making your whole body blaze with light? What of sending power to and fro over the earth at will and making it do its work anywhere and almost anyhow?

HOW IT FEELS TO INVENT.

Mr. Tesla told me that his greatest pleasure was in his work, and that he could conceive no moment so exciting and rapturous as that connected with the discovery of a new principle which, when put into use, would revolutionize the work of the world. Take, for instance, the invention which brought forth the apparatus used in the transmission of power at Niagara Falls. Said he, as he took me to a great coil of wire wound about a stationary magnet, which was connected with the dynamo, and held above it a little glass globe in which was a steel wheel moving on a pivot: "I had been working upon that experiment for a long time, and this was the test. I knew that if I were correct that the wheel in this globe would revolve as soon as I turned on the electricity. It did revolve, and I knew I had discovered what would revolutionize the labor of the world. You can run all sorts of power by that principle. You can take power from Niagara and bring it to New York. The cars can be pulled by it, factories run, houses heated and dinners cooked. I cannot describe my sensation when I saw the wheel revolve. I thought I should go crazy, and I went to my laboratory and took some bromide of potassium to quiet me.

"It has been the same in some of my experiments with electric lights and other things. No; the greatest rapture one can have is to discover a new force or series of forces, which will reduce man's working necessities to the minimum. I do not believe in laziness, and I should like to see the loafer wiped from the face of the earth; but I want that those who are willing to work should accomplish their results with the least labor and in the best way."

HOW TESLA WORKS.

As to Mr. Tesla himself, there is no harder worker known. He told me that he seldom slept more than four hours of a night, and during some periods not more than three. When in the thick of a new invention it is hard to sleep. His work is always with him and he says that his mind sometimes works in his sleep. He awakes in the morning to find that the problem which had worried him when he went to bed has been practically solved over night. He has always been a light sleeper. His mother died at seventy and she never took more than four hours' sleep. His father was a light sleeper.

Tesla is a peculiar worker. Failures do not trouble him. After he undertakes a thing and decides that it should come out a certain way, he keeps on experimenting and experimenting, believing in his success. He says that if he doubted his ability it would make him crazy. He seems to have a dual mind. He told me that he often found himself carrying on two trains of thought at the same time, and said that while he was talking to me he could see the figures of some of his calculations behind me and could carry them on at the same time.

TESLA'S NEW INVENTIONS.

And now to Mr. Tesla's latest discoveries. If he has what he thinks he has he will revolutionize labor and give man greater benefits than have come from any inventor since the world began. Indeed, the statements made me tonight in the mouth of any other man would be a fair test of insanity. But many of Tesla's wild statements of the past have been verified by great working inventions. He said he could harness Niagara, and through his experiments in the rotary magnetic fields Niagara is now furnishing a power equal to that of tens of thousands of horses, and electrical works are being run by the same principle all over the globe. The New York subway, for instance, is founded upon it. Tesla demonstrated that wireless telegraphy could be done in 1893, and it is a question whether his inventions in that field are not prior to those of Marconi or De Forrest.

Tonight he told me that he had almost completed inventions by which he could send electrical power to any distance without wires, and that in any quantity, small or great. Said he:

"I have proved that power can be thus transmitted. Let us suppose I have my plant at Niagara and you are running a sugar factory in Australia; by my discoveries it will be possible to send you a hundred, five hundred or a thousand horsepower for your factory, and to supply the same regularly by the force furnished from Niagara Falls. Suppose you are traveling in the wilds of the Andes and make your camp on the shores of Lake Titicaca. By the outcome of this principle you may have telegraphed to you there instantaneous reports of the news of the world as it happens from time to time. You may cook your dinner over an electric fire thus transmitted, and you may have the same at will on any part of the globe. We shall be able to send power from place to place at will, and that at such a small cost that it will be industrially profitable."

TRANSMISSION OF ELECTRICAL ENERGY WITHOUT WIRES.

"How did you discover that this might be done, Mr. Tesla?" I asked.

"I have for years been working on the transmission of electrical energy, and in 1898 established a laboratory on the edge of the Rocky mountains near Colorado Springs. My laboratory there was over six thousand feet high, higher than the top of Mount Washington, and I had extraordinary conditions for my experiments. Colorado is famous for its natural displays of electrical force. The earth at times is alive with electrical vibrations and the air is full of electricity. I have seen 12,000 lightning discharges within two hours and all within a radius of 30 miles of my laboratory. These discharges were of great violence, some of them looking like trees of fire on the heavens. It was among such discharges that I had my electrical instruments and studied the principles of electrical transmission through the earth and air. One day while watching the lightning I noticed that discharges afar often affected instruments in my laboratory more than those near by. Upon examination I found that this could not be caused by the difference of intensity in the individual discharges.

"What could it be?

"Through instruments made for the purpose I tested the matter from time to time and finally came to the conclusion that the vibrations caused by the lightning moved around the world and that there were stationary waves. I could gauge the discharges near the laboratory and see them fade away and after a certain fixed period find them returning with almost no loss of power. In short, this planet, as big as it is, was acting as a conductor, and I became convinced that upon it not only telegraphic messages, but also the modulations of the human voice and electrical power in unlimited amounts, could be carried around the entire globe and sent to any part of it with hardly any perceptible loss. With my transmitter I actually sent electrical vibrations around the world and received them again, and I then went on to develop my machinery. I had, as I have told you, been studying and inventing along the lines of electrical transmission and was ready to take advantage of my discovery. I have since so improved the means of individualization and isolation that such energy may be sent in any amount to any fixed place without danger of its going elsewhere or affecting others, and I believe the individualization can be carried out to almost any degree."

NIAGARA FOR THE WORLD.

"Will this enable the power of Niagara to be sent anywhere over the world?"

"Yes. I have been experimenting at my laboratory on Long Island. I have machinery and buildings there which have cost in the neighborhood of $350,000, and the results show me that a plant could be erected at Niagara which can transmit its force to any place desired. I am designing such a plant now at my laboratory, and would have had it completed had it not been for unforeseen delays, which have nothing to do with its technical features. The design which I have adopted will have a transmitter which will emit a wave complex of a total maximum activity of 10,000,000 horse power, 1 per cent. of which is enough to girdle the globe. This enormous rate of energy delivery—it is twice as much as the force of Niagara Falls—is obtainable only by the use of certain artifices which I shall make known some time in the future.

"We have been offered 10,000 horse power from the Canadian Power company. What I want to do is to build machinery there and transmit this power to different parts of the globe. The value of that amount of horse power would be about $200,000 per year, and a plant erected to take advantage of it will pay large dividends."

"How much would the plant cost?"

"It might cost in the neighborhood of $2,000,000, but its value would be enormous, and its success would revolutionize the working forces of the globe. It would result in other plants being erected otherwheres and in the utilization of all the great water falls for the work of man."

MOTHER EARTH PUT TO WORK.

"By this invention every live part of Mother Earth's body would be brought into action. Energy will be collected all over the globe in amounts small or large, as it may exist, ranging from a fraction of one to a few horse power or more. Every water fall can be utilized, every coal field made to produce energy to be transmitted to vast distances, and every place on earth can have power at small cost. One of the minor uses might be the illumination of isolated homes. We could light houses all over the country by means of vacuum tubes operated by high frequency currents. We could keep the clocks of the United States going and give every one exact time; we could turn factories, machine shops and mills, small or large, anywhere, and I believe could also navigate the air.

THE TRANSMISSION OF INTELLIGENCE.

"One of the most important features of this invention," said Mr. Tesla, "will be the transmission of intelligence. It will convert the entire earth into a huge brain, capable of responding in every one of its parts. By the employment of a number of plants, each of which can transmit signals to all parts of the world, the news of the globe will be flashed to all points. A cheap and simple receiving device, which might be carried in one's pocket, can be set up anywhere on sea or land, and it will record the world's news as it occurs, or take such special messages as are intended for it. If you are in the heart of the Sahara, your wife can telegraph to you from Washington, and if the instrument is properly made you alone will get the message. A single plant of a few horse power could operate hundreds of such instruments, so that the invention has an infinite working capacity and will cheapen the transmission of all kinds of intelligence."

Frank G. Carpenter.

ELECTRIC AUTOS.

Nicola Tesla's View of the Future in Motive Power.

[Special Cor. Manufacturers' Record.]
New York, December 27.

In view of the great interest which is being taken in the articles published by the Manufacturers' Record and some of the magazines on the development of new power-producers, through the internal-combusion engine, for use for transportation purposes both by land and sea, the following signed statement, made by Mr. Nicola Tesla after a discussion of a new type of auto-bus designed by Mr. Charles A. Lieb, mechanical engineer of the Manhattan Transit Co., will doubtless be read with much general interest:

"New York, December 17.

"*Mr. Albert Phenis, Special Correspondent Manufacturers' Record, New York*:

"Dear Sir—Replying to your inquiry of yesterday, the application of electricity to the propulsion of automobiles is certainly a rational idea. I am glad to know that Mr. Lieb has undertaken to put it into practice. His long experience with the General Electric Co. and other concerns must have excellently fitted him for the task.

"There is no doubt that a highly-successful machine can be produced on these lines. The field is inexhaustible, and this new type of automobile, introducing electricity between the prime mover and the wheels, has, in my opinion, a great future.

"I have myself for many years advocated this principle. You will find in numerous technical publications statements made by me to this effect. In my article in the Century, June, 1900, I said, in dealing with the subject: 'Steamers and trains are still being propelled by the direct application of steam power to shafts or axles. A much greater percentage of the heat energy of the fuel could be transformed in motive energy by using, in place of the adopted marine engines and locomotives, dynamos driven by specially-designed high-pressure steam or gas engines, by utilizing the electricity generated for the propulsion. A gain of 50 to 100 per cent. in the effective energy derived from the fuel could be secured in this manner. It is difficult to understand why a fact so plain and obvious is not receiving more attention from engineers.'

"At first glance it may appear that to generate electricity by an engine and then apply the current to turn a wheel, instead of turning it by means of some mechanical connection with the engine, is a complicated and more or less wasteful process. But it is not so; on the contrary, the use of electricity in this manner secures great practical advantages. It is but a question of time when this idea will be extensively applied to railways and also to ocean liners, though in the latter case the conditions are not quite so favorable. How the railroad companies can persist in using the ordinary locomotive is a mystery. By providing an engine generating electricity and operating with the current motors under the cars a train can be propelled with greater speed and more economically. In France this has already been done by Heilman, and although his machinery was not the best, the results he obtained were creditable and encouraging. I have calculated that a notable gain in speed and economy can also be secured in ocean liners, on which the improvement is particularly desirable for many reasons. It is very likely that in the near future oil will be adopted as fuel, and that will make the new method of propulsion all the more commendable. The electric manufacturing companies will scarcely be able to meet this new demand for generators and motors.

"In automobiles practically nothing has been done in this direction, and yet it would seem they offer the greatest opportunities for application of this principle. The question, however, is which motor to employ—the direct-current or my induction motor. The former has certain preferences as regards the starting and regulation, but the commutators and brushes are very objectionable on an automobile. In view of this I would advocate the use of the induction motor as an ideally simple machine which can never get out of order. The conditions are excellent, inasmuch as a very low frequency is practicable and more than three phases can be used. The regulation should offer little difficulty, and once an automobile on this novel plan is produced its advantages will be readily appreciated.

"Yours very truly, N. TESLA."

The Transmission of Electrical Energy Without Wires As a Means for Furthering Peace.

By NIKOLA TESLA.

UNIVERSAL PEACE, assuming it to be in the fullest sense realizable, might not require eons for its accomplishment, however probable this may appear, judging from the imperceptibly slow growth of all great reformatory ideas of the past. Man, as a mass in movement, is inseparable from sluggishness and persistence in his life manifestations, but it does not follow from this that any passing phase, or any permanent state of his existence, must necessarily be attained through a *stataclitic* process of development.

Our accepted estimates of the duration of natural metamorphoses, or changes in general, have been thrown in doubt of late. The very foundations of science have been shaken. We can no longer believe in the Maxwellian hypothesis of transversal ether-undulations and the literal truth of its corollaries. The practical utilization of electrical vibrations, this most important field of human endeavor, particularly in the advancement of philanthropy and peace, was in no small measure retarded by that fascinating illusion, which I since long hoped to dispel. I have noted with satisfaction the first signs of a change of scientific opinion. The brilliant discovery of the exceptionally "radio-active" substances, radium and polonium, by Mrs. Sklodowska Curie, has likewise afforded me much personal gratification, being an eclatant confirmation of my early experimental demonstrations, of electrified radiant streams of primary matter or corpuscular emanations (*Electrical Review*, New York, 1896-1897), which were then received with incredulity. They have awakened us from the poetical dream of an intangible conveyor of energy, weightless, structureless ether, to the plain, palpable reality of a ponderous medium of coarse particles, or bodily carriers of force. They have led us to a radically new interpretation of the changes and transformations we perceive. Enlightened by this recognition, we cannot say the sun is hot, the moon is cold, the star is bright, for all these might be purely electrical phenomena. If this be the case, then even our conceptions of time and space may have to be modified.

So, too, as regards the organic world, a similar revolution of thought is distinctly observable. In biological and zoological research the bold ideas of Haensel have found support in recent discoveries. A heretic belief in such possibilities as the artificial production of simple living material aggregates, the spontaneous natural creation of complex organisms and willful sex control, is gaining ground. We still brush it aside, but not with pedantic disdain as before. The fact is—our faith in the orthodox theory of slow evolution is being destroyed!

Thus a state of human life vaguely defined by the term "Universal Peace," while a result of cumulative effort through centuries past, might come into existence *quickly*, not unlike a crystal suddenly forms in a solution which has been slowly prepared. But just as no effect can precede its cause, so this state can never be *brought on* by any pact between nations, however solemn. Experience is made before the law is formulated, both are related like cause and effect. So long as we are clearly conscious of the expectation, that peace is to result from such a parliamentary decision, so long have we a conclusive evidence that we are not fit for peace. Only then when we shall feel that such international meetings are mere formal procedures, unnecessary except in so far as they might serve to give definite expression to a common desire, will peace be assured.

To judge from current events we must be, as yet, very distant from that blissful goal. It is true that we are proceeding towards it rapidly. There are abundant signs of this progress everywhere. The race enmities and prejudices are decidedly waning. A recent act of His Excellency, the President of the United States, is significant in this respect. We begin to think cosmically. Our sympathetic feelers reach out into the dim distance. The bacteria of the "Weltschmerz," are upon us. So far, however, universal harmony has been attained only in a single sphere of international relationship. That is the postal service. Its mechanism is working satisfactorily, but—how remote are we still from that scrupulous respect of the sanctity of the mail bag! And how much farther again is the next milestone on the road to peace—an international judicial service equally reliable as the postal!

The coming meeting at the Hague, now indefinitely postponed, can only consider temporary expedients. General disarmament being for the present entirely out of question, a proportionate reduction might be recommended. The safety of any country and of the world's commerce depending not on the absolute, but relative amount of war material, this would be evidently the first reasonable step to take towards universal economy and peace. But it would be a hopeless task to establish an equitable basis of adjustment. Population, naval strength, force of army, commercial importance, water-power, or any other natural resource, actual or prospective, are equally unsatisfactory standards to consider.

In view of this difficulty a measure suggested by Carnegie might be adopted by a few strong countries to scare all the weaker ones into peace. But while for the time being such a course may seem advisable, the beneficial effects of this homœopathic treatment of the martial disease could hardly be lasting. In the first place, a coalition of the leading powers could not fail to create an organized opposition, which might result in a disaster all the greater as it was long deferred. The ultimate falling out of the virtuous, peace-dictating nations, as *certain* as the law of gravitation, should be all the more reckoned with, as it would be extremely demoralizing. Again, it is by no means demonstrated that any combination of a few powers would have sufficient authority.

To conquer by sheer force is becoming harder and harder every day. Defensive is getting continuously the advantage of offensive, as we progress in the satanic science of destruction. The new art of controlling electrically the movements and operations of individualized automata at a distance without wires, will soon enable any country to render its coasts impregnable against all naval attacks. It is to be regretted, in this connection, that my proposal to the United States Navy four years ago, to introduce this invention, did not receive the least encouragement. Also that my offer to Secretary Long to establish telegraphic communication across the Pacific Ocean by my wireless system was thrown in the naval waste basket in Washington, quite *sans façon*. At that time I had already announced in the *Century Magazine* of June, 1900, my successful "girdling" of the globe with electrical impulses (stationary waves), and my "telautomata" had been publicly exhibited. But that was not the fault of the naval officials, for then these inventions of mine were decried as bald, visionary schemes, loudest indeed by those who have since become Crœsuses of Promise—in "light" storage batteries, "Ocean" telephony and "transatlantic" wireless telegraphy, yet remained to this day—Sisyphuses of Attainment. Had only a few "telautomatic" torpedoes been constructed and adopted by our navy, the mere moral influence of this would have been powerfully and most beneficially felt in the present Eastern complication. Not to speak of the advantages which might have been secured through the direct and instantaneous transmission of messages to our distant colonies and scenes of the present barbarous conflicts. Since advancing that principle, I have invented a number of improvements, making it possible to direct such a torpedo, submersible at will, from a distance much greater than the range of the largest gun, with *unerring* precision, upon the object to be destroyed. What is still more surprising, the operator will not need to see the infernal engine or even know its location, and the enemy will be unable to interfere, in the slightest, with its movements by any electrical means. One of these devil-telautomata will soon be constructed, and I shall bring it to the attention of governments. The development of this art must unavoidably arrest the construction of expensive battleships as well as land fortifications, and revolutionize the means and methods of warfare. The distance at which it can strike, and the destructive power of such a *quasi-intelligent* machine being for all practical purposes unlimited, the gun, the armor of the battleship and the wall of the fortress, lose their import and significance. One can prophesy with a Daniel's confidence that skilled electricians will settle the battles of the near future. But this is the least. In its effect upon war and peace, electricity offers still much greater and more wonderful possibilities. To stop war by the perfection of engines of destruction alone, might consume centuries and centuries. Other means must be employed to hasten the end. What are these to be? Let us consider.

Fights between individuals, as well as governments and nations, invariably result from misunderstandings in the broadest interpretation of this term. Misunderstandings are always caused by the inability of appreciating one another's point of view. This again is due to the ignorance of those concerned, not so much in their *own*, as in their *mutual* fields. The peril of a clash is aggravated by a more or less predominant sense of combativeness, possessed by every human being. To resist this inherent fighting tendency the

best way is to dispel ignorance of the doings of others by a systematic spread of general knowledge. With this object in view, it is most important to aid exchange of thought and intercourse.

Mutual understanding would be immensely facilitated by the use of one universal tongue. But which shall it be, is the great question. At present it looks as if the English might be adopted as such, though it must be admitted that it is not the most suitable. Each language, of course, excels in some feature. The English lends itself to a terse, forceful expression of facts. The French is precise and finely distinctive. The Italian is probably the most melodious and easiest to learn. The Slavic tongues are very rich in sound but extremely difficult to master. The German is unequaled in the facility it offers for coining and combining words. A practical answer to that momentous question must perforce be found in times to come, for it is manifest that by adopting one common language the onward march of man would be prodigiously quickened. I do not believe that an artificial concoction, like Volapuk, will ever find universal acceptance, however time-saving it might be. That would be contrary to human nature. Languages have grown into our hearts. I rather look to the possibility of a reversion to the old Latin or Greek mother tongues, basing myself in this conclusion on the Spencerian law of rhythm. It seems unfortunate that the English-speaking nations, who are now fittest to rule the world, while endowed with extraordinary energy and practical intelligence, are singularly wanting in linguistic talent.

Next to speech we must consider permanent records of all kinds as a means for disseminating general information, or that knowledge of *mutual* endeavor which is chiefly conducive to harmony. Here the newspapers play by far the most important part. They are undoubtedly more effective than institutions of learning, libraries, museums and individual correspondence, all combined. The knowledge they convey is, on the whole, superficial anl sometimes defective, but it is poured out in a mighty stream that reaches far and wide. Disregarding the force of electrical invention, that of journalism is the greatest in urging us to peace. Our schools are instrumental, mainly, in the furtherance of special thorough knowledge in our *own* fields, which is destructive of concordance. A world composed of crass specialists only would be perpetually at war. The diffusion of general knowledge through libraries and similar sources of information is very slow. As to individual correspondence, it is principally useful as an indispensable ingredient of the cement of commercial interest, that most powerful binding material between heterogeneous masses of humanity. It would be hard to overestimate the beneficial influence of the marvelous and precise art of photography, nor can that of other arts or means of recording be ignored. But a simple reflection will show that the peace-making force of all permanent, printed or other records, resides not in themselves. It must be sought elsewhere. This is also true of speech.

Our senses enable us to perceive only a minute portion of the outside world. Our touch, taste and smell, require actual contact. Our hearing extends to a small distance. Our sight is impeded by intervening bodies and shadows. To know each other we must reach beyond the sphere of our sense perceptions. We must transmit our intelligence, travel, transport the materials and transfer the energies necessary for our existence. Following this thought we now realize, forcibly enough to dispense with argument, that of all other conquests of man, without exception, that which is most desirable, which would be most helpful in the establishment of universal peaceful relations is—the complete *ANNIHILATION OF DISTANCE.*

To achieve this wonder, electricity is the one and only means. Inestimable good has already been done by the use of this all-powerful agent, the nature of which is still a mystery. Our astonishment at what has been accomplished would be uncontrollable were it not held in check by the expectation of greater miracles to come. That one, the greatest of all, can be viewed in three aspects: *Dissemination of intelligence, transportation, and transmission of power.*

Referring to the first, the present systems of telegraphic and telephonic communication are very limited in scope. The conducting channels are costly and of small working capacity. There is serious inductive disturbance, and storms render the service unsafe which, moreover, is too expensive. A vast improvement will be effected by placing the wires underground and insulating them artificially, by refrigeration. Their working capacity also could be indefinitely augmented by resorting to the new principle of "individualization," which I have more recently announced, permitting the simultaneous transmission of thousands of telegraphic and telephonic messages, without interference, over a single wire. The public would be already profiting from these great advances were it not for the stolid indifference of the leading companies engaged in the transmission of intelligence. But new concerns are springing into existence and the near future will witness a great transformation along these two lines of invention. The submarine cables are subject to still greater limitations. Some obstacles to rapid signaling, through them, seem insuperable. The attempts to overcome these have been numerous, but so far all have proved futile. The celebrated mathematician, O. Heaviside, and several able electricians following in his footsteps, have fallen into the singular error that rapid telegraphy and even telephony through ocean cables would be made practicable by the use of induction coils. Inductances might be to some extent helpful on comparatively short lines with thick paper insulation; on long lines insulated with rubber or gutta-percha they would be positively detrimental. Improvements will, undoubtedly, be made, but great electrostatic capacity and unavoidable loss of energy in the insulation and surrounding conductors will always restrict the usefulness of these delicate and precious nerves of commerce. Apart from all this, the transmission through artificial conductors is necessarily confined to a small number of stations.

It is therefore evident that the abolishment of all these drawbacks by the conveyance of signals or messages without wires, as I have undertaken in my "world" telegraphy and telephony, will be of the greatest moment in the furtherance of peace. The unifying influence of this advance will be felt all the more, as it will not only completely annihilate distance, but also make it possible to operate from a single "world" telegraphy plant, an unlimited number of receiving stations distributed all over the globe, and with equal facility, irrespective of location. Within a few years a simple and inexpensive device, readily carried about, will enable one to receive on land or sea the principal news, to hear a speech, a lecture, a song or play of a musical instrument, conveyed from any other region of the globe. The invention will also meet the crying need for cheap transmission to great distances, more especially over the oceans. The small working capacity of the cables and the excessive cost of messages are now fatal impediments in the dissemination of intelligence which can only be removed by transmission without wires.

The deficiencies of Hertzian telegraphy have created in the public mind the impression that exclusive or private messages without the use of artificial channels are impracticable. As a matter of fact, nothing could be more erroneous. Ever since its first appearance in 1891, I have denied the commercial possibilities of the system of signaling by Hertzian or electromagnetic waves, and my forecasts have been fully confirmed. It lends itself little to tuning, still less to the higher artifices of "individualization," and transmission to considerable distances is wholly out of the question. Portentous claims for this method of communication were made three years ago, but they have been unable to stand the hard, cruel test of time. Moreover, I have recently learned through the leading British electrical journal (*Electrician,* London, February 27, 1903), that some experimenters have abandoned all their own and have been "converted" to my methods and appliances, without my approval and officiation. I was both astonished and pained—astonished at the nonchalance and lack of appreciation of these men, pained at the inability exhibited in the construction and use of my apparatus. My high hopes raised by that excellent journal, however, are still to be realized, for I have ascertained that His Majesty the King of England, His Excellency the President of the United States, and other persons of exalted positions have, after all, not conferred upon me the imperishable honor of graciously condescending to the use of my coils, transformers and high-potential methods of transmission, but have exchanged their august greetings through the medium of a cable in the old-fashioned way. What has been actually achieved by Hertzian telegraphy can only be conjectured.

Quite different conditions exist in my system in which the electromagnetic waves or radiations are designedly minimized, the connection of one of the terminals of the transmitting circuit to the ground having, itself, the effect of reducing the energy of these radiations to about one-half. Under observance of proper rules and artifices the distance is of little or no consequence, and by skillful application of the principle of "individualization," repeatedly referred to, the messages may be rendered both non-interfering and non-interfer-

able. This invention, which I have described in technical publications, attempts to imitate, in a very crude way, the nervous system in the human body. It was the outcome of long-continued tests demonstrating the impossibility of satisfying rigorous commercial requirements by my earlier system, based on simple tuning, in which the selective quality is dependent on a single characteristic feature. In this later improvement the exclusiveness and non-interferability of impulses transmitted through a common channel result from cooperative association of a *number* of distinctive elements, and can be pushed as far as desired. In actual practice it is found that by combining only two vibrations or tones, a degree of privacy sufficient for most purposes is attained. When three vibrations are combined, it is extremely difficult, even for a skilled expert, to read or to disturb signals not intended for him, with four it is a vain undertaking. The probability of his getting the secret combinations at the right moments and in proper order, is much smaller than that of drawing an ambo, terno or quaterno, respectively, in a lottery. From experimental facts, I conclude that the invention will permit the simultaneous transmission of several millions of separately distinguishable messages through the earth, which, strangely enough, is in this respect much superior to an artificial conductor. This number ought to be sufficient to meet all the pressing necessities of intelligence transmission for at least one century to come. It is important to observe that but one "world" telegraphy plant, such as I am now completing, will have a greater working capacity than *all the ocean cables combined.* Once these facts are recognized this new art, which I am inaugurating, will sweep the world with the force of a uragan.

In transportation a great change is now going on. The trolley lines are being extended, the steam locomotive is making place for the electric motor. The ocean liners are adopting the turbine. Land travel is being improved by the automobile. The waterfalls are being harnessed and the energy used in the propulsion of cars. The advantages of first generating electricity by a prime mover, and then applying the current to produce mechanical motion, are being more and more appreciated. To the majority, this may appear a roundabout way of doing, but in reality it is as direct as the driving of a pulley from another by a belt. The idea is already being applied to railroads, and automobiles of this new type are making their appearance. The ocean vessels are bound to follow. An immense and virgin field will be thus opened up to the manufacturers of electric machinery. Effort towards saving time and money is characteristic of all modern methods of transportation. In many of these new developments, the artificial insulation of the high-tension mains by refrigeration will be very useful. However paradoxical, it is true, that by the use of this invention, power for all industrial purposes can be transmitted to distances of many hundreds of miles, not only without any loss, but with appreciable *gain* of energy. This is due to the fact that the conductor is much colder than the surrounding medium. The operativeness of this method is restricted to the use of a gaseous refrigerant, no known liquid permitting the attainment of a sufficiently low temperature of the transmission line. Hydrogen is by far the best cooling agent to employ. By its use electric railways can be extended to any desired distance. Owing to the smallness of ohmic loss, the objections to the multiphase system disappear and induction motors with closed coil armatures can be adopted. I find that even transmission through a submarine cable, as from Sweden to England, of great amounts of power is perfectly practicable. But the ideal solution of the problem of transportation will be arrived at only when the complete annihilation of distance in the transmission of power in large amounts shall have become a commercial reality. That day we shall invade the domain of the bird. When the vexing problem of aerial navigation, which has defied his attempts for ages, is solved, man will advance with giant strides.

That electrical energy can be economically transmitted without wires to any terrestrial distance, I have unmistakably established in numerous observations, experiments and measurements, qualitative and quantitative. These have demonstrated that it is practicable to distribute power from a central plant in unlimited amounts, with a loss not exceeding *a small fraction of one per cent.* in the transmission, even to the greatest distance, twelve thousand miles—to the opposite end of the globe. This seemingly impossible feat can now be readily performed by any electrician familiar with the design and construction of my "high-potential magnifying transmitter," the most marvelous electrical apparatus of which I have knowledge, enabling the production of effects of unlimited intensities in the earth and its ambiant atmosphere. It is, essentially, a freely vibrating secondary circuit of definite length, very high self-induction and small resistance, which has one of its terminals in intimate direct or inductive connection with the ground and the other with an elevated conductor, and upon which the electrical oscillations of a primary or exciting circuit are impressed under conditions of resonance. To give an idea of the capabilities of this wonderful appliance, I may state that I have obtained, by its means, spark discharges extending through more than one hundred feet and carrying currents of one thousand amperes, electromotive forces approximating twenty million volts, chemically active streamers covering areas of several thousand square feet, and electrical disturbances in the natural media *surpassing* those caused by lightning, in itensity.

Whatever the future may bring, the universal application of these great principles is fully assured, though it may be long in coming. With the opening of the first power plant, incredulity will give way to wonderment, and this to ingratitude, as ever before. The time is not distant when the energy of falling water will be man's life energy. So far only about three million horse-power have been harnessed by my system of alternating-current transmission. This is little, but corresponds, nevertheless, to the adding of sixty million indefatigable laborers, working virtually without food and pay, to the world's population. The projects which have come to my own attention, however, contemplate the exploitation of water-powers aggregating something like one hundred and fifty million horse-power. Should they be carried out in a quarter of a century, as seems probable from present indications, there will be, on the average two such untiring laborers for every individual. Long before this consummation, coal and oil must cease to be important factors in the sustenance of human life on this planet. It should be borne in mind that electrical energy obtained by harnessing a waterfall is probably fifty times more effective than fuel energy. Since this is the most perfect way of rendering the sun's energy available, the direction of the future material development of man is clearly indicated. He will live on "white coal." Like a babe to the mother's breast will he cling to his waterfall. "Give us our daily waterfall," will be the prayer of the coming generations. *Deus futurus est deus aquae deiectus!*

But the fact that stationary waves are producible in the earth is of special and, in many ways, still greater significance in the intellectual development of humanity. Popularly explained, such a wave is a phenomenon generically akin to an echo—a result of reflection. It affords a positive and uncontrovertible experimental evidence that the electric current, after passing into the earth travels to the diametrically opposite region of the same and rebounding from there, returns to its point of departure with virtually undiminished force. The outgoing and returning currents clash and form nodes and loops similar to those observable on a vibrating cord. To traverse the entire distance of about twenty-five thousand miles, equal to the circumference of the globe, the current requires a certain time interval, which I have approximately ascertained. In yielding this knowledge, nature has revealed one of its most precious secrets, of inestimable consequence to man. So astounding are the facts in this connection, that it would seem as though the Creator, himself, had electrically designed this planet just for the purpose of enabling us to achieve wonders which, before my discovery, could not have been conceived by the wildest imagination. A full account of my discoveries and improvements will be given to the world in a special work which I am preparing. In so far, however, as they relate to industrial and commercial uses, they will be disclosed in patent specifications most carefully drawn.

As stated in a recent article (ELECTRICAL WORLD AND ENGINEER, March 5, 1904), I have been since some time at work on designs of a power plant which is to transmit ten thousand horse-power without wires. The energy is to be collected all over the earth at many places and in varying amounts. It should not be understood that the practical realization of this undertaking is *necessarily* far off. The plans could be easily finished this winter, and if some preliminary work on the foundations could be done in the meantime the plant might be ready for operation before the close of next fall. We would then have at our disposal a unique and invaluable machine. Just this *one* oscillator would advance the world a century. Its civilizing influence would be felt even by the humblest dweller in the wilderness. Millions of instruments of all kinds, for all imaginable purposes, could be operated from that one machine. Universal time could be distributed by simple inexpensive clocks requiring no attention and running with nearly mathematical

precision. Stock-tickers, synchronous movements and innumerable devices of this character could be worked in unison all over the earth. Instruments might be provided for indicating the course of a vessel at sea, the distance traversed, the speed, the hour at any particular place, the latitude and longitude. Incalculable commercial advantages could be thus secured and countless accidents and disasters avoided. Here and there a house might be lighted or some other work requiring a few horse-power performed. What is far more important than this, flying machines might be driven in any part of the world. They could be made to travel swiftly because of their small weight and great motive power. My intention would be to utilize this first plant rather as means of enlightenment, to collect its power in very small amounts, and at as many places as possible. The knowedge that there is throbbing through the earth energy readily available everywhere, would exert a strong stimulus on students, mechanics and inventors of all countries. This would be productive of infinite good. Manufacture would receive a fresh and powerful incentive. Conditions, such as never existed before in commerce, would be brought about. Supply would be ever inadequate to demand. The industries of iron, copper, aluminum, insulated wire and many others, could not fail to derive great and lasting benefits from this development.

The economic transmission of power without wires is of all-surpassing importance to man. By its means he will gain complete mastery of the air, the sea and the desert. It will enable him to dispense with the necessity of mining, pumping, transporting and burning fuel, and so do away with innumerable causes of sinful waste. By its means, he will obtain at any place and in any desired amount, the energy of remote waterfalls—to drive his machinery, to construct his canals, tunnels and highways, to manufacture the materials of his want, his clothing and food, to heat and light his home—year in, year out, ever and ever, by day and by night. It will make the living glorious sun his obedient, toiling slave. It will bring peace and harmony on earth.

Over five years have elapsed since that providential lightning storm on the 3d of July, 1899, of which I told in the article before mentioned, and through which I discovered the terrestrial stationary waves; nearly five years since I performed the great experiment which, on that unforgettable day, the dark God of Thunder mercifully showed me in his vast, awe-sounding laboratory. I thought then that it would take a year to establish commercially my wireless girdle around the world. Alas! my first "world telegraphy" plant is not yet completed, its construction has progressed but slowly during the past two years. And this machine I am *building* is but a plaything, an oscillator of a maximum activity of only ten million horse-power, just enough to throw this planet into feeble tremors, by sign and word—to telegraph and to telephone. *When* shall I see completed that first power plant, that big oscillator which I am *designing?* From which a current stronger than that of a welding machine, under a tension of one hundred million volts, is to rush through the earth! Which will deliver energy at the rate of one thousand million horse-power—one hundred Falls of Niagara combined in one, striking the universe with blows—blows that will wake from their slumber the sleepiest electricians, if there be any, on Venus or Mars! . . . It is not a dream, it is a *simple feat of scientific electrical engineering,* only expensive—blind, faint-hearted, doubting world! . . . Humanity is not yet sufficiently advanced to be willingly led by the discoverer's keen searching sense. But who knows? Perhaps it is better in this present world of ours that a revolutionary idea or invention instead of being helped and patted, be hampered and ill-treated in its adolescence—by want of means, by selfish interest, pedantery, stupidity and ignorance; that it be attacked and stifled; that it pass through bitter trials and tribulations, through the heartless strife of commercial exisence. *So* do we get our light. So all that was great in the past was ridiculed, condemned, combatted, suppressed—only to emerge all the more powerfully, all the more triumphantly from the struggle.

Practical Letters from our Readers.

[*The Editor invites readers to make use of this column for the full discussion of matters of practical and mutual interest. Letters may be signed with a* nom-de-plume *if desired, but the full name and address of the sender* MUST *invariably be attached, though not necessarily intended for publication.*]

The Use of Tesla Coils for *X*-ray Work.

TO THE EDITOR OF *The Model Engineer*.

DEAR SIR,—Mr. Howgrave-Graham's criticism of my article of November 17th loses much of its point by reason of the fact that he omitted to first read up my previous article of May 28th, 1903. Indeed, I, or anyone fully acquainted with the facts of the case, might be excused if on reading in "*X*-rays Simply Explained" a reference to the article just referred to, I came to the conclusion that even then Mr. Graham had not read it, and consequently had not seen the photographic illustration which accompanied it. The criticism thus becomes purely academic. I quite agree with Mr. Howgrave Graham on one point—viz., that an *iron core* would be worse than useless in such a coil. Mr. Graham refers to the matter in one of his articles dated June 4th, 1903, MODEL ENGINEER, page 533, and for my part I should find it difficult to say who first suggested the use of an *iron* core for high frequency transformer or self-induction coils. Certainly, unless I am greatly mistaken, Tesla makes no reference to it in his article of April, 1892, *Journal of the Institute of Electrical Engineers*.

Early in the history of Röntgen ray work a more or less simple form of Tesla coil was introduced for the purpose of supplementing or augmenting the power of existing induction coils in the production of the *X*-rays. More than one list of "*X*-ray apparatus and accessories" contains estimate for this; £6 10s. appears to have been the usual figure, and, presumably, making every and liberal allowance for profits, there was a nicely made and more or less efficient piece of apparatus for the money. The only objection raised to the method was, so far as my memory serves, that the life of the tube was considerably shortened from the fact probably that the apparatus and tube were used frequently without sufficient discrimination.

That a simple form of Tesla (and I refer to apparatus on a small scale) was used, and *found efficient*, is indisputable. Personally, I never purchased such a coil, but simple forms were described from time to time in *Electricity* and, I believe, the *English Mechanic*. My first was made several years ago, and was used by me mainly for demonstration purposes, as I found that for a long continued run, or when it was desired to show the *X*-rays through a cryptoscope, there was much less risk of damage to one's *coil* (less current being required), while the deterioration of the *tube* was thought to be somewhat exaggerated. At all events, I was more disposed to risk a focus-tube than my coil!

Theoretically, I suppose, the Tesla discharges being oscillatory, by this arrangement *X*-ray should *not be so completely harnessed* for purposes of visual examination by means of a screen, as they undoubtedly are. Photographically, also, starting from similar premises, the absence of absolute sharpness—and this might be disputed—over a wider area is balanced by their greater power of *penetration*, and the consequent increase in the number of subjects available for purposes of delineation.

An inspection of the tube while working shows

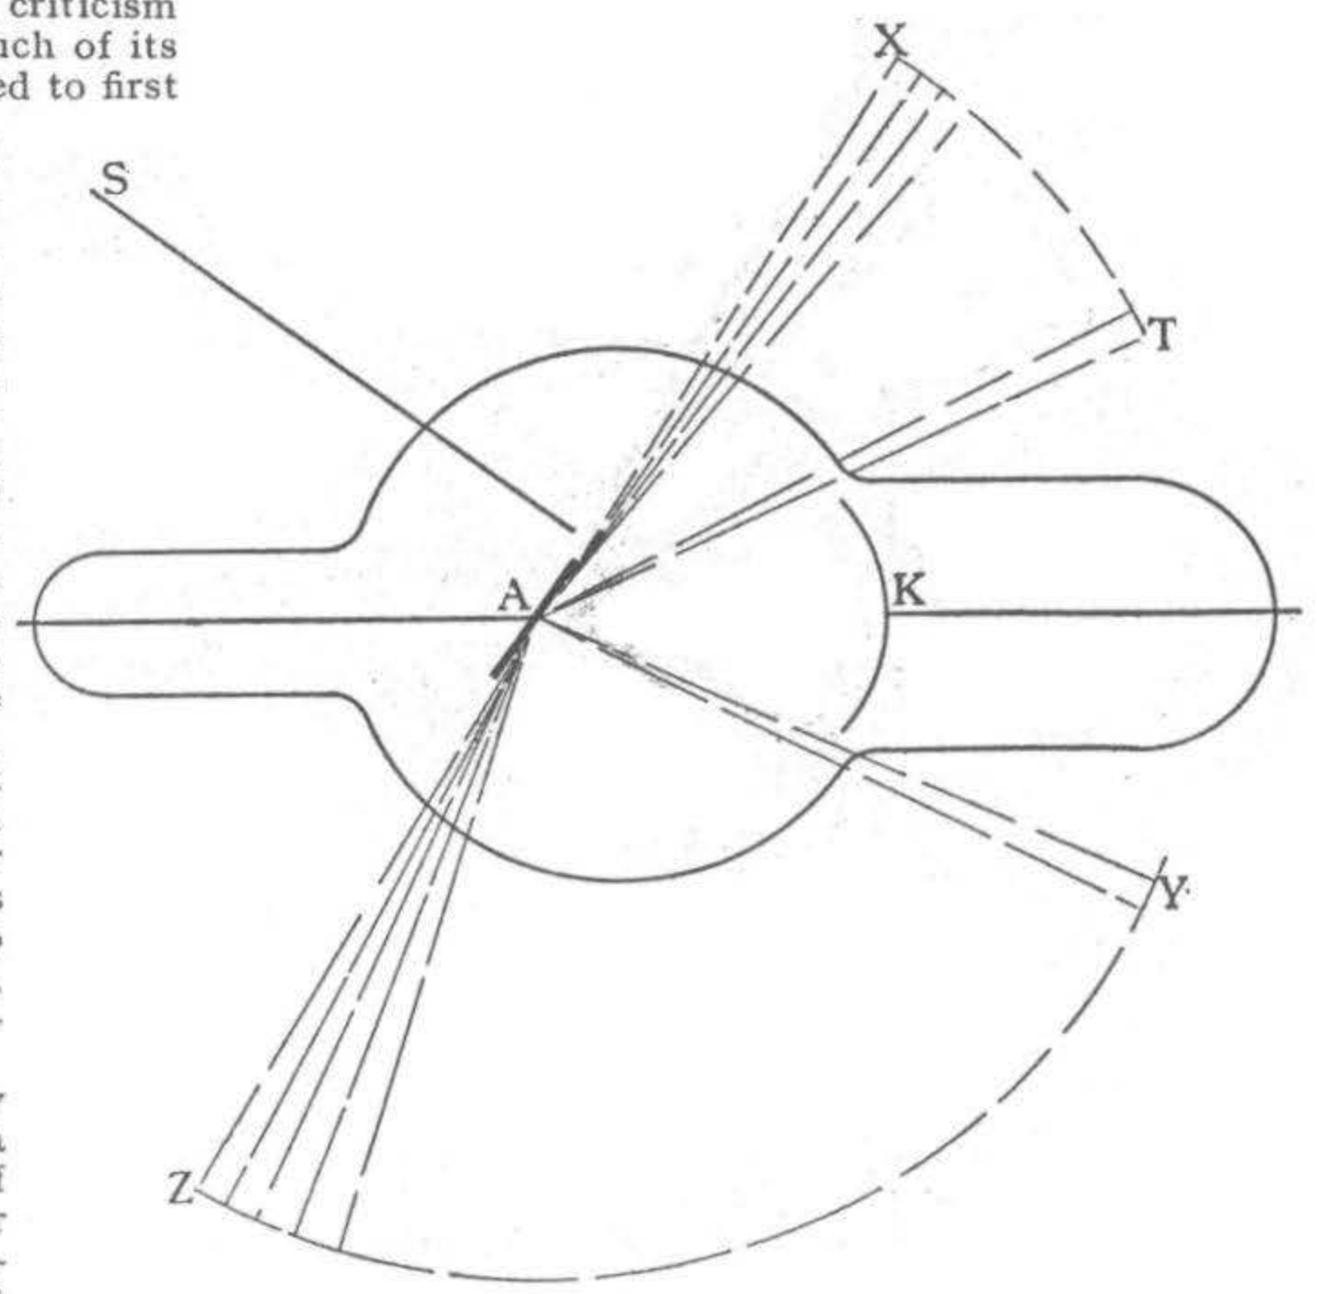

FIG. 1.

that (referring to Fig. 1) there is the usual line of demarcation from Z to X, not perhaps so strongly marked as when using induction coil only, but still perfectly definite; between S and X there is also fluorescence, and in greater volume than between X and T. Examining the tube also per cryptoscope, slowly revolving same, faint glimmers of rays are visible here and there, but nothing in comparison with the volume of *X*-rays which illumine the screen from Z to Y; and the conclusion arrived at must be that although A and K are constantly alternating, it is always to the advantage of the illuminated space between Y and Z. It would

appear that every other half-wave or reversal *does not decrease the efficiency of working*, but results photographically, in not a loss of definition exactly, but rather a *diffusion of focus*, which is not unpleasing.

The accompanying radiograph, which was taken for the purpose of this letter, is one more proof of

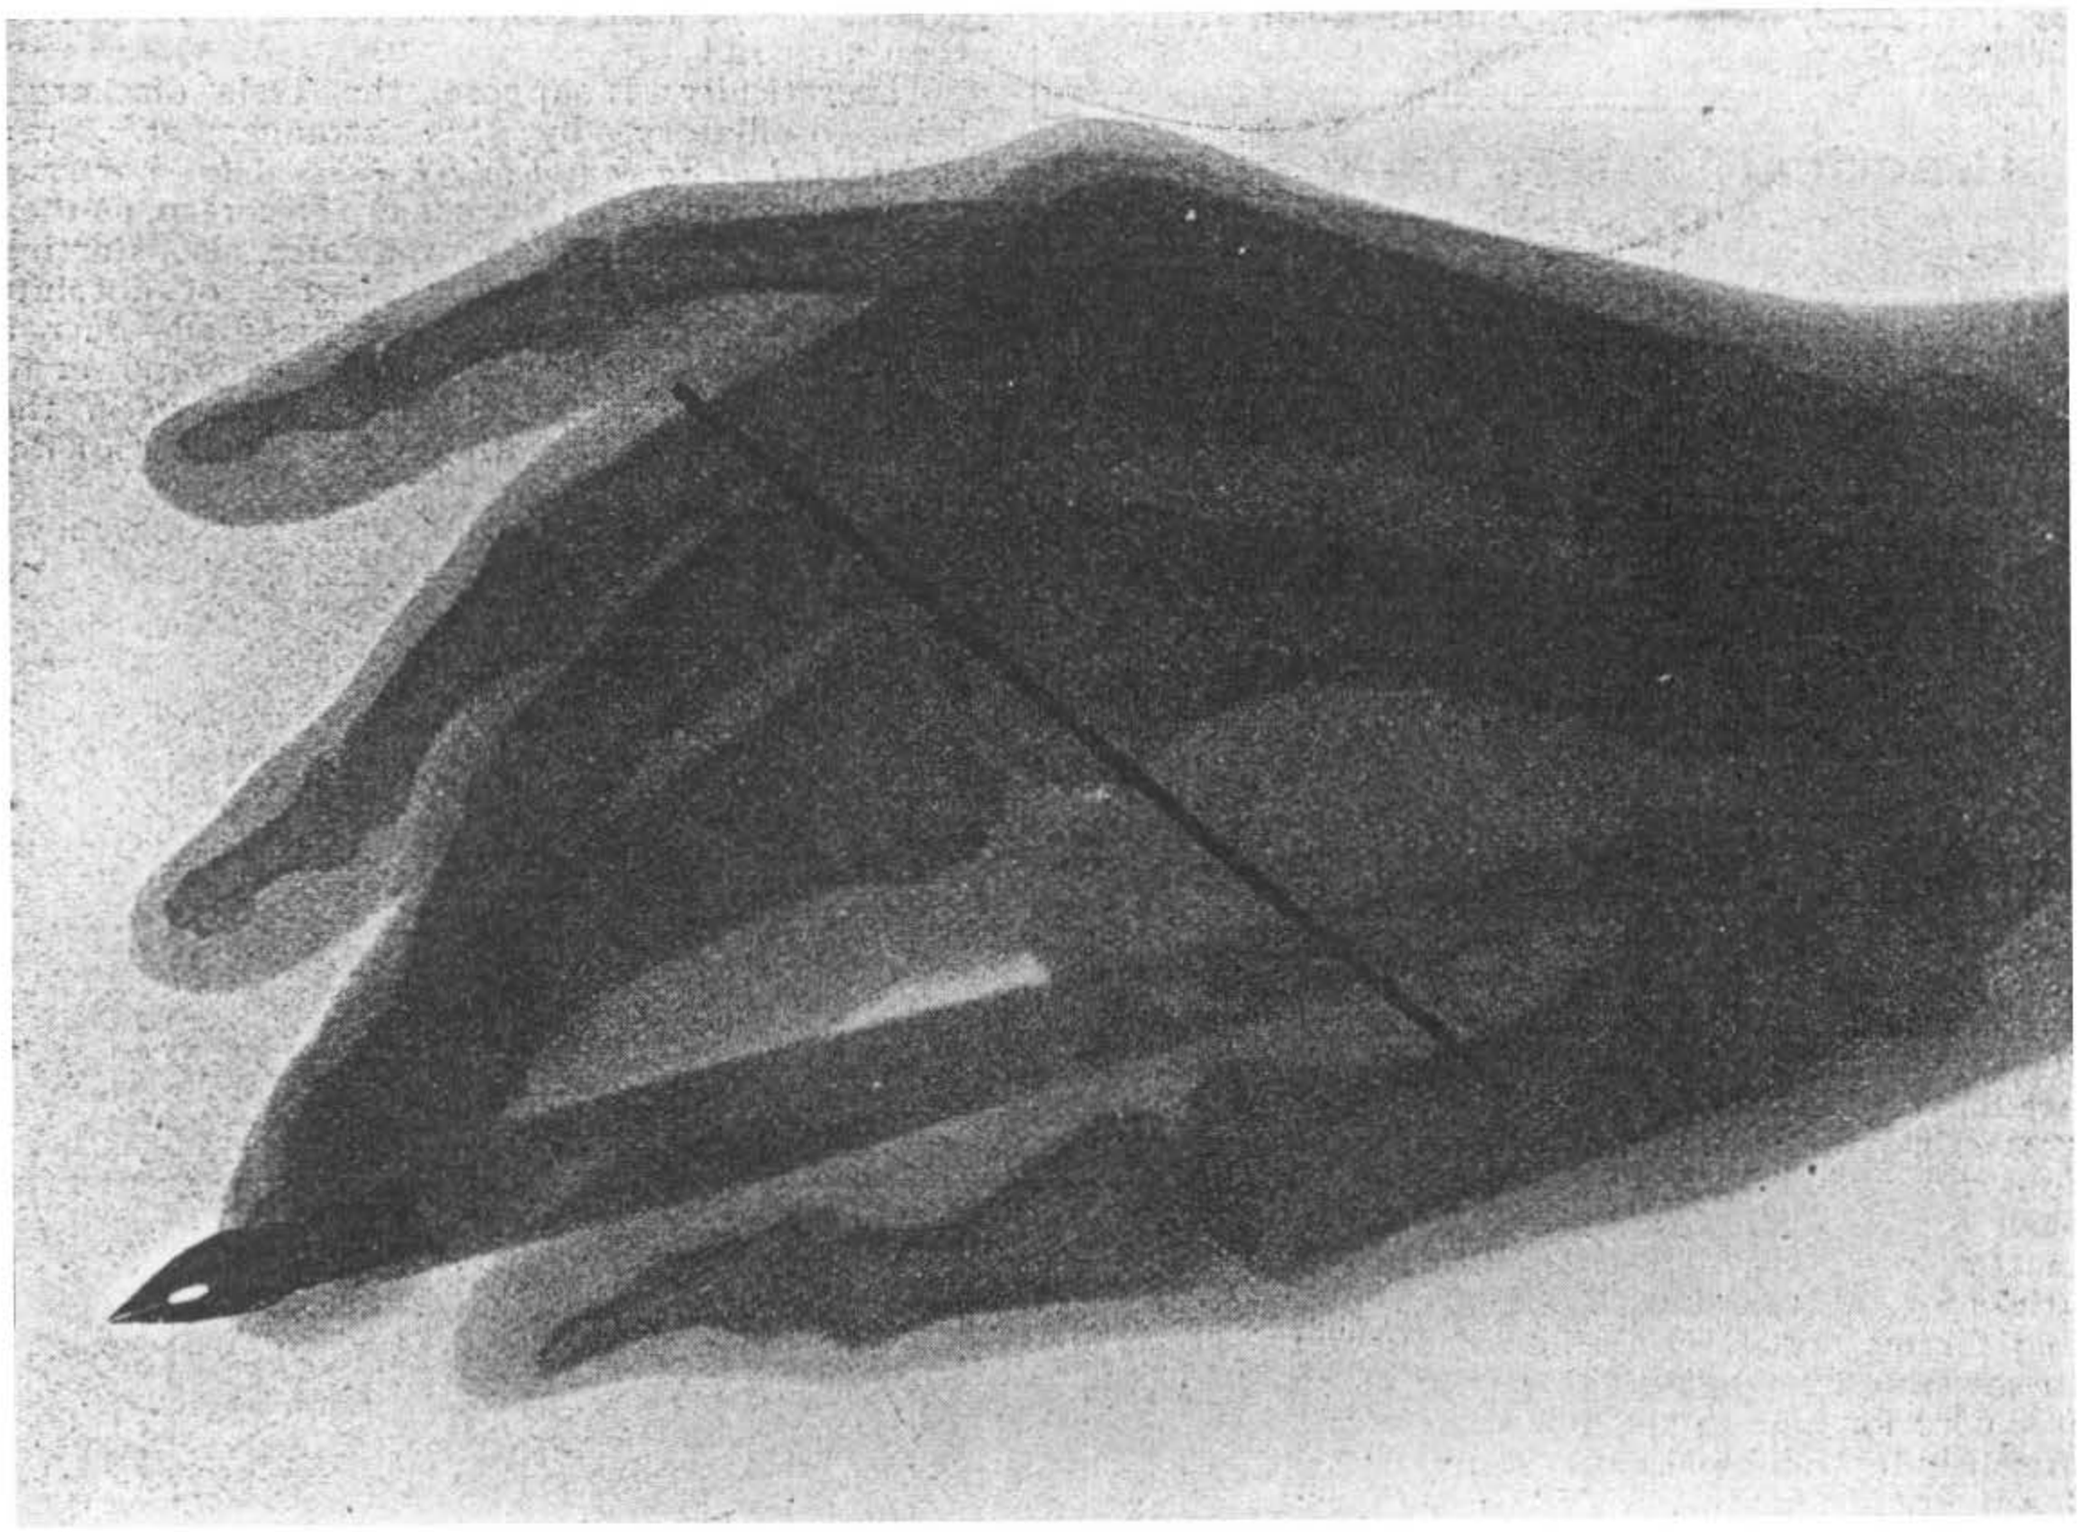

FIG. 2.

the efficiency of the apparatus. Here the hand is arched, the apex of the figure being 3 ins. above the base—a distinct handicap from the photographic point of view, as, for uniform sharpness in the usual way, the bones should be co-planar. The radiograph may, I think, be left to tell its own tale.

—Yours truly,
J. PIKE.

Nottingham.

An Important Decision Sustaining the Tesla Patents.

On February 20 Judge Seaman, in the United States Circuit Court for the Eastern District of Wisconsin, handed down a decision sustaining the Tesla patents owned by the Westinghouse Electric and Manufacturing Company. The defendant was the National Electric Company, and infringement was claimed of the broad rights covered in Tesla patents Nos. 381,968, 381,969, 382,280 and 382,281. Judge Seaman, in Milwaukee, on February 24 enjoined the defendant company from the further sale of synchronous motors. The decision in the suit is the first that has been obtained in the litigation begun some time ago by the Westinghouse company to prevent the sale of synchronous motors and rotary converters by American manufacturers not enjoying a license under the Tesla polyphase motor patents. A decision is pending in the United States Circuit Court for the Southern District of Ohio in the suit brought by the Westinghouse company against the Bullock Electric Manufacturing Company, alleging infringement of the same patent rights. The final hearing in the latter suit was conducted before Judge Thompson, in Cincinnati, on February 7 and 8.

The Tesla patents involved in these suits have been the subject of considerable litigation in the past few years. The action instituted by the Westinghouse company a number of years ago against the Thomson-Houston Company, for alleged infringement of the Tesla patents, was discontinued upon the execution of a patent agreement under which the General Electric Company has for several years manufactured and sold induction and synchronous motors and rotary converters. A number of manufacturers have been enjoined from manufacturing induction motors, but the decision by the Wisconsin court is the first court ruling that the synchronous motor is within the generic Tesla invention. Judge Seaman's decision, covering the main points, is as follows:

"With the excellent and thorough review of the earlier patents and prior art, and the well considered concurrent view of the novelty and scope of the Tesla invention covered by the patents (thus appearing in several of these opinions) I am relieved of any need to attempt an analysis of the general showing in the present case, which departs from the prior cases only in respect of the application of the invention of the synchronous-motor type. Although the enquiry thus presented is not free from difficulty—involving abstruse discussion and distinctions in the electrical art which are perplexing to the non-expert understanding, and are not clarified by the many pages of conflicting expert testimony—the arguments at the bar were clear and well directed, and I am convinced that the issue as now presented is within narrow compass and governed by tests for its solution which are not complicated.

"The defendant's contentions are, in substance, that the Tesla invention, embodied in each of the patents, is the rotating field mode of operation, which is 'the production of the conjoint effect of out-of-phase currents of a progressive shifting by the polarity,' and thus 'identical in its effect with that of a rotating physical magnet;' that it is limited to a self-starting motor so operated and both by the terms of the patents and the state of the art, the defendant's synchronous motor with direct-current excitation is not within the invention; that the defendant's synchronous motor is simply a reversed 'two-phase alternating-current dynamo of the prior art used as a generator,' adapted to alternating use; and that the claims of patents 381,969 and 382,281, which bring in 'direct-current excitation producing synchronous operation,' must be limited to such use 'after the motor is started by the Tesla means and method and brought up to speed.' If the invention is so limited by the prior art it is plain that the defendant escapes infringement. On the other hand, if not so restricted, it is equally clear that the patents are broad enough to reach the defendant's means and methods of operation.

"The Tesla discovery for which these patents were granted revolutionized the art of electrical power transmission, as well demonstrated in the record from both judicial and scientific standpoints. Judge Townsend's definition in reference to the generic patents in the New England Granite case, repeatedly approved by other courts, is adopted for this consideration, namely, 'Tesla's invention, considered in its essence, was the production of a continuously rotating or whirling field of magnetic forces for power purposes by generating two or more displaced or different phases of the alternating current, transmitting such phases, with their independence preserved, to the motor, and utilizing the displaced phases as such in the motor.' So viewed the patent monopoly was rightly granted for its brief term to the use of the means and methods thus discovered. While it could not exclude the known uses of the prior art, it is surely entitled to be protected against like motor structure and mode of operation, not clearly disclosed in the prior art, and the patent claims to that end must be fairly construed in conformity with the rule applicable to such inventions. I am of the opinion, therefore, that the several contentions for the defendant are either without force or untenable for the following reasons:

"Whether the effect of the Tesla invention in its production of the 'whirling field of magnetic force' is identical with that of a rotating physical magnet, as argued by experts and counsel, does not impress me as material to this issue. Nor does it seem material that in the one form of motor 'the rotation is produced by the unaided effect of alternating out-of-phase currents,' as described by counsel, and that so applied a self-starting motor is obtained. The discovery was of means and method in the polyphase rotating field motor to produce the whirling field of force, and employment thereof was patentable with or without direct-current excitation of the armature or secondary element. So the fact that its use produced a self-starting motor without the aid of such excitation can not alone serve to limit the invention to that effect, and I find no such limitation in the terms of the patent. The quotations from the arguments of counsel and experts for the complainant in prior cases, urging the distinction of this self-starting effect in reference to the application of the generic patents to non-synchronous motors, are without force in the present controversy, and it is unnecessary to ascertain their consistency or inconsistency with the interpretation sought on this hearing. Unless limitation to self-starting motors arises out of the prior art none can be imposed upon the claims in suit.

"The further propositions urged by way of defence—aside from the defence founded upon prior inventions of the synchronous type to be considered—are these (1) that the synchronous motor of the defendant is the old generator of the art, simply reversed; and (2) that the Tesla invention is not present therein, because (as asserted) 'the prepondering magnetization of the' direct current displaced and obliterates the 'shifting alternating-current magnetization,' or Tesla 'whirling field of force.' However specious both propositions appear on their face and in the argument, neither of them impresses me as controlling.

"I believe that no proposition in the able and extended arguments on the part of the defence have been overlooked in my consideration of this case, although it has not seemed needful to discuss all of them for the purposes of this opinion. My conclusions are that the defendant's synchronous motor structure and operation are within the generic invention as patented, and expressly covered by the claims of Nos. 381,969 and 382,281; that the invention is utilized in the defendant's motor operation, notwithstanding the introduction of direct-current excitation to make it synchronous, in lieu of the full realization of the revolving field effect for self-starting; that such supplemental aid does not escape infringement, with or without advantage in such associations; and that, in any view the combination patents referred to are not limited to after-effect of the direct-current excitation, but apply to the defendant's combination. Decree will be entered accordingly as prayed in the bill."

Tesla Polyphase Patents held to Cover Polyphase Synchronous Motors.

On February 20 Judge Seaman, of the Circuit Court of the United States of the Eastern District of Wisconsin, handed down an opinion holding that the fundamental Tesla patents, issued May 1, 1888, cover the rotary converter and synchronous motor operated by polyphase currents. The defendants to the suit contended that Tesla's invention is the rotating field mode of operation and this is limited to a self-starting motor so operated; that the defendants' synchronous motor with direct-current excitation is not within the invention, being simply a reversed two-phase alternating-current dynamo of the prior art used as a generator; and that the claims in the Tesla patents which introduced "direct-current excitation producing synchronous operation" must be limited to such use after the motor is started by the Tesla means and method and brought up to speed. The court held that if the invention is to be so limited the defendant escapes infringement; on the other hand, if not so restricted, it is equally clear that the claims of the patents are broad enough to reach the defendants' means and method of operation.

The court stated that the Tesla discovery was of means and methods in the polyphase rotating field motor to produce the "whirling field of force," and employment thereof was obtainable, with or without direct-current excitation of the armature or secondary element. The fact that its use produced a self-starting motor without the aid of such excitation cannot alone serve to limit the invention to that effect. The theory advanced of the obliteration of the alternating-current magnetization by that of the direct current of the secondary element of the motor, the court held, was not material, as it is unquestionable that the Tesla invention is brought into the operation of the motor and the structure is within the patent description.

As to the Bradley patent, upon which stress was laid in the argument as showing a polyphase machine stated to be adapted for use "as a motor when fed or actuated by alternating currents," this is subsequent in date of patent issue to the Tesla patents, though the original application bears date prior to that of Tesla. The testimony of Mr. Bradley and his attorney cannot affect the interpretation which must be given the disclosure of the invention in the original application, and if such application can be treated as a disclosure of the prior art, it fails to reach the Tesla conception. Its deficiencies in that regard were pointed out in previous suits involving the Tesla patents.

The conclusions of the court are that the defendants' synchronous motor structure and operation are within the generic invention covered by the claims of two of the fundamental Tesla patents; that the invention is utilized in the defendants' motor operation, notwithstanding the introduction of direct-current excitation to make it synchronous in lieu of the full realization of the revolving field effect for self-starting; that such supplemental aid does not escape infringement with or without advantage in such association; and that, in any view the combination patents referred to are not limited to after effect of direct-current excitation, but apply to the defendants' combination.

The parties of the suit were the Westinghouse Electric & Manufacturing Company and the National Electric Company.

Tesla Synchronous Motor Patents Upheld.

In pursuance of a decision handed down by him on February 20th, in the United States Circuit Court for the Eastern District of Wisconsin, sustaining the contention of the Westinghouse Electric and Manufacturing Company that synchronous motors made by the National Electric Company were an infringement of the broad rights covered in Tesla patents Nos. 381,969 and 382,281, Judge Seaman, in Milwaukee, on February 24th, enjoined the National company from the sale of such motors. The decision in the suit is the first that has been obtained in the litigation begun some time ago by the Westinghouse company to prevent the sale of synchronous motors and rotary converters by American manufacturers not enjoying a license under the Tesla polyphase-motor patents. The hearing in the suit against the National Electric Company was conducted before Judge Seaman on February 6th and 7th, Thomas B. Kerr and Parker W. Page appearing for the Westinghouse company.

The Tesla patents involved in suit have been the subject of considerable litigation in the last few years. Other manufacturers have been enjoined from manufacturing induction motors, but the decision in the suit against the National company is the first court ruling that the synchronous motor is within the generic Tesla invention. Extracts from Judge Seaman's decision are as follows:

"The defendant's contentions are, in substance, that the Tesla invention, embodied in each of the patents, is the rotating-field mode of operation, which is 'the production of the conjoint effect of out-of-phase currents of a progressive shifting by the polarity,' and thus 'identical in its effect with that of a rotating physical magnet' that it is limited to a self-starting motor so operated, and both by the terms of the patents and the state of the art, the defendant's synchronous motor with direct-current excitation is not within the invention; that the defendant's synchronous motor is simply a reversed 'two-phase alternating-current dynamo of the prior art used as a generator,' adapted to alternative use; and that the claims of patents 381,969 and 382,281, which bring in 'direct-current excitation producing synchronous operation,' must be limited to such use 'after the motor is started by the Tesla means and method and brought up to speed.' If the invention is so limited by the prior art it is plain that the defendant escapes infringement. On the other hand, if not so restricted, it is equally clear that the claims of the patents are broad enough to reach the defendant's means and method of operation."

"The Tesla discovery for which these patents were granted revolutionized the art of electrical power transmission, as well demonstrated in the record from both judicial and scientific standpoints. Judge Townsend's definition, in reference to the generic patents in the New England Granite case, repeatedly approved by other courts, is adopted for this consideration, namely, 'Tesla's invention, considered in its essence, was the production of a continually rotating or whirling field of magnetic forces for power purposes by generating two or more displaced or different phases of the alternating current, transmitting such phases, with their independence preserved, to the motor, and utilizing the displaced phases as such in the motor.' So viewed, the patent monopoly was rightly granted for its brief term to the use of the means and methods thus discovered. While it could not exclude the known uses of the prior art, it is surely entitled to be protected against like motor structure and mode of operation, not clearly disclosed in the prior art, and the patent claims to that end must be fairly construed in conformity with the rule applicable to such inventions. I am of the opinion, therefore, that the several contentions for the defendant are either without force or untenable."

"Whether the effect of the Tesla invention in its production of the 'whirling field of magnetic force' is identical with that of a rotating physical magnet, as argued by experts and counsel, does not impress me as material to this issue. Nor does it seem material that in the one form of motor 'the rotation is produced by the unaided effect of alternating out-of-phase currents,' as described by counsel, and that so applied a self-starting motor is obtained. The discovery was of means and method in the polyphase rotating-field motor to produce the whirling field of force, and employment thereof was patentable with or without direct-current excitation of the armature or secondary element. So the fact that its use produced a self-starting motor without the aid of such excitation cannot alone serve to limit the invention to that effect, and I find no such limitation in the terms of the patent. The quotations from the arguments of counsel and experts for the complainant in prior cases, urging the distinction of this self-starting effect in reference to the application of the generic patents to non-synchronous motors, are without force in the present controversy, and it is unnecessary to ascertain their consistency or inconsistency with the interpretation sought on this hearing. Unless limitation to self-starting motors arises out of the prior art none can be imposed upon the claims in suit."

"The further propositions urged by way of defense—aside from the defense founded upon prior inventions of the synchronous type to be considered—are these—(1) that the synchronous motor of the defendant is the old generator of the art, simply reversed, and (2) that the Tesla invention is not present therein, because (as asserted) 'the preponderating magnetization of the direct current displaced and obliterates the 'shifting alternating-current magnetization,' or Tesla's 'whirling field of force.' However specious both propositions appear on their face and in the argument, neither of them impresses me as controlling."

"I believe that no proposition in the able and extended arguments on the part of the defense have been overlooked in my consideration of this case, although it has not seemed needful to discuss all of them for the purposes of this opinion. My conclusions are that the defendant's synchronous-motor structure and operation are within the generic invention as patented, and expressly covered by the claims of Nos. 381,969 and 382,281; that the invention is utilized in the defendant's motor operation, notwithstanding the introduction of direct-current excitation to make it synchronous, in lieu of the full realization of the revolving-field effect for self-starting; that such supplemental aid does not escape infringement, with or without advantage in such associations; and that, in any view, the combination patents referred to are not limited to after-effect of the direct-current excitation, but apply to the defendant's combination. Decree will be entered accordingly as prayed in the bill."

The National Electric Company has given notice of appeal from the injunction. On its behalf, it is also declared that the patents expire in May of this year in any event.

A WIDE APPLICATION OF THE TESLA POLYPHASE patents was made by Judge Seaman in the Federal Circuit Court at Milwaukee, Wis., in the decision in a suit brought by the Westinghouse Electric & Mfg. Co., of Pittsburg, Pa., against the National Electric Co., of Milwaukee, Wis. The complainants, owners of the Tesla polyphase patents, sought to enjoin the defendant from the further sale of synchronous motors (reversed alternating-current generators). Their contention was that the claim of Tesla for producing a rotating field by means of currents differing in phase applies to synchronous polyphase motors and rotary converters as well as to induction motors. This contention was upheld by the court. The material portion of the decision delivered Feb 24, 1905, is reproduced in the "Electrical Review" of March 4, from which we quote the following:
